AN INTRODUCTION

Hepatitis C is an infectious disease caused by the hepatitis C virus (HCV) that primarily affects the liver. The virus persists in the liver in about 75% to 85% of those initially infected. It often leads to liver disease and occasionally cirrhosis. In some cases, those with cirrhosis will develop complications such as liver failure, liver cancer, or esophageal and gastric varices (R). Ribavirin as anti viral drug has therapeutic efficacy against HCV, in a combination with other drugs, but Ribavirin has many adverse effects; some of which are severe as hemolytic anemia which sometimes necessitate patients to discontinue therapy, which sometimes necessitate patients to discontinue therapy, giving supplement therapy as erythropoietin, or at last blood transfusion is needed. To overcome or minimize the risk of Ribavirin adverse effects, Ribavirin should be targeted to reticulo endothelial system (RES) mainly to the liver. Erythrocyte has been exploited as potential carrier for bioactive substances, especially biopharmaceuticals, in recent decades1,2,3. Erythrocytes are preferred as a drug carrier system because they have many advantages as availability in abundant cells in the body, biocompatibility, biodegradability, loading with a variety of drugs and considerable circulation life-span of the auto logous carrier erythrocytes which allow them to serve as prolonged release intravenous reservoirs for various drugs. On the other hand, abnormal or aged erythrocytes are destructed or phagocytosed by the RES and they can be used as drug targeting carriers to RES organs mainly liver, spleen and kidney. The drugs or bioactive substances can be successfully loaded or entraped into erythrocytes by different methods as osmosis based method (e.g. hypotonic dilution, pre swelling and hypotonic dialysis methods), chemical method (e.g., chemical perturbation of the erythrocyte membrane), an electrical pulse method and endocytosis method. In this paper, the human erythrocytes have been loaded by Ribavirin
using endocytosis method and the in-vitro characteristics of the prepared cellular carriers have been evaluated. The obtained results from this study such as remarkable shape and morphological changes erythrocytes make it possible to target the Ribavirin a high dose in a short time period, thereby potentially augmenting the biological response using a relatively low drug dose, consequently diminishing of deleterious adverse effects of Ribavirin as hemolytic anemia. This benefit is intended as the scope of work of this study.

MATERIALS AND METHODS
Ribavirin was obtained as gift from MEMPHIS, El-Amirya-Cairo–Egypt; Sodium chloride, potassium di hydrogen phosphate, Disodium hydrogen phosphate, calcium chloride and d-glucose were supplied from El-Nasr Pharm. Chem. Company, (Cairo, Egypt); Potassium chloride is provided from Flukachemie AGCH, Switzerland; Membrane PTFE (0.2µm) Disposable syringe filter from Macherey-Nagel GmbH, Germany; Magnesium Chloride hexahydrate and methanol were purchased from El-Gomeria pharm company (Cairo-Egypt); Adenosine 5'-Triphosphate was obtained as a gift from SIGMA - pharmaceutical industries-Quesna city-Egypt.

Collection of specimen
The blood specimens were collected from apparently healthy donors not suffered from acute and chronic diseases. Blood samples were collected in heparinized tubes.

Preparation of erythrocyte suspension
The collected specimens were centrifuged for 5 min at 5000 rpm (Biofuge Primo centrifuge maximum 17.000 rpm (England)). The plasma and the buffy coat were removed by aspiration. Erythrocytes were washed three times in cold phosphate buffer saline (PBS) pH 7.4 with centrifugation for 5 min at 5000 rpm, then the hematocrit was adjusted to 45 % using (PBS).

Preparation of Ribavirin loaded erythrocytes by endocytosis technique
In 2ml eppendorff tubes, 400µl of washed erythrocytes were added to 400µl of previous prepared loading buffer containing different concentrations of Ribavirin, gentle mixing to avoid blood hemolysis and the obtained suspension was incubated for different times at 37°C (Oven, Heraeus, UT 5060 E (Germany)). The final obtained suspension was centrifuged for 5 min at 5000 rpm and the supernatant was discarded. The obtained pellet was washed for 2 times in cold BPS with centrifugation for 5 min at 5000 rpm.

Effect ofRibavirin concentrations on the loading efficiency. To determine the effect of Ribavirin concentration on loading efficiency, different drug concentrations (10 mg, 15 mg, 20 mg, and 25 mg) were used for all selected incubation times. The results were compared to obtain the more suitable concentration for loading process which produce most excellent loading parameters. Data shown are the mean±SD and were analyzed by one way ANOVA using Graph-Pad Prisme software version 6.07 (Graph Pad, San Diego, California). P values less than 0.001 were considered statistically significant.

Characterization of the prepared ribavirin loaded erythrocytes
Loading parameters
To evaluate the final erythrocyte carriers, three indices were defined as loading parameters (loaded amount, entrapment efficiency and cell recovery).

1. Loaded amount: The total amount of Ribavirin entrapped in 1ml of the final packed erythrocytes.

2. Entrapment efficiency: The percentage ratio of the loaded amount of Ribavirin to the amount added during the entire loading process.

3. Cell recovery: The percentage ratio of the hematocrit value of the final loaded cells to that of the initial packed cells, both measured using equal suspension volumes.

Hematological Indices
Normal erythrocytes, erythrocytes suspended in PBS and Ribavirin-loaded erythrocytes were counted. The mean corpuscular volume (MCV: the estimated average cell volume), the mean corpuscular hemoglobin (MCH: the estimated average hemoglobin content per each cell), and the mean corpuscular hemoglobin content (MCHC: the estimated hemoglobin content per 100 ml of cell volume) were measured using Hematology analyzer (Hematology analyzer Swelab auto counter 920–Eo2- 126 13 Stockholm Sweden).

Osmotic fragility behavior of Ribavirin loaded erythrocytes
To evaluate the resistance of erythrocytes membranes against the osmotic pressure changes of their surrounding media, 25µl Ribavirin loaded erythrocytes sample was added to each of a series of 2.5ml NaCl solutions at predetermined concentrations 0.0, 0.1, 0.15, 0.25, 0.35, 0.4, 0.45, 0.5, 0.6, 0.7, 0.8 and 0.9 g% of NaCl. After gentle mixing and standing for 15 min at room temperature, the erythrocyte suspensions were centrifuged at 5000 rpm for 5 min. The absorbance of the supernatant was measured UV spectrophotometer at 540nm (Ultraviolet spectrophotometer, Shimadzu 1800 (Japan). The released hemoglobin was expressed as percentage absorbance of each sample in reference to a completely lysed sample prepared by diluting of packed cells with 1.5ml of distilled water. An osmotic
fragility index was defined for native and Ribavirin loaded erythrocytes. Data shown are the mean±SD and were analyzed by one way ANOVA using Graph-Pad Prisme software version 6.07 (Graph Pad, San Diego, California). P values less than 0.05 were considered statistically significant. Scanning electron microscopy (SEM)

To investigate the possible morphological changes of erythrocytes upon loading process, samples of Ribavirin loaded erythrocytes and control were prepared as following stepwise procedure:

1. Fixation in 4% glutaraldehyde and 0.2M sodium cacodylate.
2. Washing with 0.15M sodium cacodylate for 10 min, two times.
3. Post fixation in 1% osmium tetroxide and 0.2M sodium cacodylate, for 2 h.
4. Washing with 0.15M sodium cacodylate for 10 min, two times.
5. Dehydration with a successive gradient of 35%, 50%, 75%, 95%, and 100% ethanol, each for 10 min.
6. Drying with pure hexamethyldisilazane for 20 min, two times.
7. Transforming the samples to staps.

Finally, the prepared samples were analyzed using an electron microscope (JOEL scanning electron microscope (JTEM) model 1010 Tokyo, Japan) after coating with gold particles by a Sputter Coater (Fisons, 7640, UK) in 18mA for 40 s at x4300 and x7000 magnifications.

In-vitro release of Ribavirin from the loaded erythrocytes

To study the release of Ribavirin from carrier erythrocytes loaded by the mentioned method of loading above, 1 ml of packed Ribavirin loaded erythrocytes was diluted to 9 ml using PBS the suspension and then mixed thoroughly by several gentle inversions. The mixture was divided into 20 portions (0.5ml each) in 1.5ml eppendorf tube. The samples were rotated vertically at 20 rpm while incubated at 37°C (Oscillating thermostatically controlled shaker, Gallent Kamp (England). At (0.5, 2, 4, 8, 12, 16 and 20) hr intervals, one of the aliquots was removed and centrifuged at 5000 rpm for 5 min. One hundred μl of the supernatants was separated for drug assay. The drug analysis was done by chromatograph.

Effect of cross linker on in-vitro release of Ribavirin loaded erythrocytes

The release of Ribavirin from erythrocytes loaded by endocytosis after treatment with glutaraldehyde as across linker was studied. One ml of packed drug loaded erythrocytes was diluted with 8.5ml of PBS and 0.5ml of 0.5% glutaraldehyde solution. The suspension was mixed thoroughly by several gentle inversions and incubated for 10 minutes. The mixture was centrifuged and the pellet resuspended again in 9ml PBS and then followed as described above.

### Table 1: Effect of Ribavirin concentrations and incubation times on the amount of Ribavirin loaded on human carrier erythrocyte at 37°C by endocytosis

| Drug concentration (mg/ml) | Drug incubation times | Ribavirin loaded (mg/ml) |
|---------------------------|-----------------------|--------------------------|
|                           | 15 min. | 30 min. | 60 min. |
| LA | EE % | LA | EE % | LA | EE % |
| 10 | 2.72±0.01 | 27.2 | 2.79±0.024 | 27.95 | 3.1±0.037 |
| 15 | 3.61±0.02 | 24.0 | 3.68±0.01 | 25.7 | 4.68±0.033 |
| 20 | 3.65±0.012 | 18.3 | 5.1±0.023 | 25.5 | 5.66±0.04 |
| 25 | 4.18±0.012 | 16.7 | 6.85±0.019 | 27.4 | 5.68±0.045 |
| 30 | 4.54±0.01 | 15.2 | 7.22±0.023 | 24.0 | 8.99±0.034 |
| 35 | 4.4±0.012 | 12.6 | 7.4±0.026 | 21.1 | 9.47±0.049 |

LA = Ribavirin loaded amount, EE% = entrapment efficiency %, Data is expressed as mean±SD (n=3)

(1). Significantly different according to time at p < 0.001; (2). Significantly different according to concentration at p < 0.001

### RESULTS AND DISCUSSION

Ribavirin uptake by endocytosis

Table 1 shows the effect of Ribavirin concentrations and the including incubation times on the amount of Ribavirin loaded on human carrier erythrocytes by endocytosis at 37°C. Figure 1 illustrate the effect of Ribavirin concentrations and the including incubation times on the Entrapment Efficiency % of Ribavirin loaded on human carrier erythrocytes by endocytosis at 37°C.

Effect of Ribavirin concentration on the loading amount

Incubation time VS Ribavirin Conc.

The amount of Ribavirin loaded using Ribavirin concentration 10 mg/ml for incubation times 15, 30 and 60 minutes. The amount of Ribavirin loaded is found to reach 2.72±0.01mg, 2.79±0.024 mg and 3.1±0.037 mg, respectively after 15, 30 and 60 minutes of incubation. It was found that the amount of Ribavirin loaded increases in direct proportionality according to the time factor till reaching the maximum loading incubation time after 60 minutes (r=0.987). Upon increasing Ribavirin concentration to 15 mg/ml for the same times mentioned above, the amount of Ribavirin loaded is found to be 3.61±0.02mg, 3.68±0.01mg and 4.68±0.033mg, respectively after the same time mentioned above.

Again, Ribavirin loaded in erythrocytes increases in direct proportionality by increasing the time factor (r=0.962). By increasing Ribavirin concentration to 20 mg/ml for the same times, the amount of drug loaded is also significantly increased at (p≤ 0.001) according to the time factor increase till reaching the maximum loading time after 60 minutes. The amount of Ribavirin loaded observed was as follows: 3.65±0.012mg, 5.1±0.023 mg and 5.66± 0.04mg, respectively.
Ribavirin loaded in erythrocytes increases in direct proportionality by increasing the time factor (r=0.905). By increasing Ribavirin concentration to become 25mg/ml, 30mg/ml or 35mg/ml, the same phenomena as discussed for (10 mg, 15 mg and 20 mg/ml) was observed and also significantly increased at (p≤ 0.001) according to the time. The maximum loaded amount for all the above mentioned concentrations at maximum loading time after 60 minutes was found at 25mg/ml. The amount of Ribavirin loaded was as follows: 4.18±0.012 mg, 6.85±0.019 mg and 9.58±0.045 mg, respectively; 4.54±0.01 mg, 7.22±0.023 mg and 8.99±0.034 mg, respectively for 30mg/ml of Ribavirin; 4.4±0.012mg, 7.4±0.026mg and 9.47±0.049 mg for 35mg/ml of Ribavirin, respectively. The amount of Ribavirin loaded in erythrocytes, in the three mentioned concentrations above for Ribavirin, was found to increase in direct proportionality. The regression coefficients obtained were r=0.983, r=0.953 and r=0.957, respectively.

**Ribavirin Conc. VS each incubation time**
The amount of Ribavirin loaded using all the applied Ribavirin concentrations (from 10mg/ml to 35 mg/ml) for each applied incubation time (15 min, 30 min and 60 min) i.e., at constant time in each experiment. The amount of Ribavirin loaded at 15 min was found to be 2.27±0.01 mg, 3.61±0.02 mg, 3.65±0.012 mg, 4.18±0.012 mg, 4.54±0.01 mg and 4.4±0.012 mg, respectively for the six Ribavirin concentrations. The above relationship shows a direct proportionality with r=0.931. The amount of Ribavirin loaded at 30 min was found to be 2.79±0.024 mg, 3.68±0.01 mg, 5.1±0.023 mg, 6.85±0.019 mg, 7.22±0.023 mg and 7.4±0.026 mg, respectively for the six Ribavirin concentrations. The above relationship shows a direct proportionality with r=0.965. The amount of Ribavirin loaded at 60 min was found to be 3.1±0.037mg, 4.68±0.033 mg, 5.66±0.04 mg, 9.58±0.045 mg, 8.99±0.034mg and 9.47±0.049 mg, respectively for the six Ribavirin concentrations. The above relationship shows a direct proportionality with r=0.931.

**Effect of Ribavirin concentrations on the entrapment efficiency % Incubation time VS Ribavirin Conc.**
The entrapment efficiency % of Ribavirin loaded using Ribavirin concentration 10 mg/ml for times 15, 30 and 60 minutes. The entrapment efficiency % of Ribavirin loaded was found to reach 27.2%, 27.95% and 31%, respectively after 15, 30 and 60 minutes of incubation. It was found that the entrapment efficiency% of Ribavirin loaded increases in direct proportionality according to the time factor till reaching the maximum loading incubation time after 60 minutes (r=0.989).

Upon increasing Ribavirin concentration to 15 mg/ml for the same times mentioned above, the entrapment efficiency % of Ribavirin loaded was found to be 24%, 25.7% and 31.1%, respectively after the same time mentioned above. Again, the entrapment efficiency % of Ribavirin loaded into erythrocytes increases in direct proportionality by increasing the time factor (r=0.994). By increasing Ribavirin concentration to 20mg/ml for the same times, the entrapment efficiency % of Ribavirin loaded was also significantly increased according to the time factor increase till reaching the maximum loading time after 60 minutes. The entrapment efficiency % of Ribavirin loaded observed was as follows: 18.3%, 25.5% and 28.3 %, respectively. The entrapment efficiency % of Ribavirin loaded in erythrocytes increases in direct proportionality by increasing the time factor (r=0.905). By increasing Ribavirin concentration to become 25mg/ml, 30mg/ml or 35mg/ml, the same phenomena as discussed for (10mg, 15mg and 20 mg/ml) was observed and also significantly increased according to the time. The maximum entrapment efficiency % of Ribavirin loaded for all the above mentioned concentrations at maximum loading time after 60 minutes was found at 25 mg/ml. The amount of Ribavirin loaded was as follows: 16.7%, 27.4% and 38.3%, respectively; 15.2%, 24% and 29.9%, respectively for 30 mg/ml of Ribavirin; 12.6%, 21.1% and 27% for 35 mg/ml of Ribavirin, respectively. The entrapment efficiency % of Ribavirin loaded into erythrocytes, in the three mentioned concentrations above for Ribavirin, was found to increase in direct proportionality. The regression coefficients obtained were r=0.983, r=0.954 and r=0.957, respectively.
relationship shows an inverse proportionality with $r=\alpha-0.974$. The entrapment efficiency % of Ribavirin loaded at 30 min. was found to be 27.95%, 25.7%, 25.5%, 27.4%, 24% and 21.1%, respectively for the six Ribavirin concentrations. The above relationship shows an inverse proportionality with $r=\alpha-0.804$. The above results indicate that the entrapment efficiency % of Ribavirin was decreased from 10 mg/ml until 20mg/ml of Ribavirin and then increased in Ribavirin concentration of 25mg/ml followed by a decrease again in the remaining Ribavirin concentrations. The entrapment efficiency % of Ribavirin loaded at 60 min was found to be 31.0%, 31.2%, 28.3%, 38.3%, 29.9% and 27.0%, respectively for the six Ribavirin concentrations. The above relationship shows an inverse proportionality with $r=\alpha-0.188$. These results confirmed the same phenomenon as described above.

The experimental work investigates the effect of time, as well as the drug concentration on the process of Ribavirin loading into human erythrocytes by endocytosis as trial to obtain Ribavirin targeted delivery system. The results indicate that the highest level of Ribavirin loaded on erythrocytes was achieved using 25mg/ml of Ribavirin at 37°C and 60 minutes incubation time. The aforementioned results proved compatible with the previous study which demonstrates the increase in the cell membrane activity upon temperature increasing up to optimum temperature 37°C\(^{17}\). Likewise, this finding is supported by another study which shows that endocytosis process is decreased by decreasing temperature\(^{18}\). The presence of some factors as toxicity factor or an energy source stimulates the endocytosis\(^{19}\). The presence of calcium ions and ATP in the formulation process stimulates the endocytosis of Ribavirin uptake by erythrocytes. This is supported by the observation viewed by Schrier et al., which stated that the calcium ions and energy source stimulate drug uptake by erythrocytes through membrane invagination and formation of endocytotic vacuoles. The drugs induced endocytosis is dependent on the persistence of erythrocyte energy sources\(^{20}\).

From the above results was found that the highest entrapment efficiency % of Ribavirin loaded was 38.3% that was given at 25mg/ml of Ribavirin after 60 minutes incubation time. After that the entrapment efficiency % of Ribavirin loaded was decreased upon increasing Ribavirin concentration. This entrapment efficiency % of Ribavirin loading is better than that obtained in interferon-alpha 2b loading study as comparison\(^{7}\).

### Table 2: Hematological parameters of control erythrocytes, sham and loaded erythrocytes obtained with Ribavirin (25mg/ml) by endocytosis

| Hematological parameters | Control Conc. | Sham encapsulated | Ribavirin Conc. 25 mg/ml |
|--------------------------|---------------|-------------------|-------------------------|
| Hct (%)                  | 38±1.16\(^a\) | 33.8±1.02         | 33.6±1.37\(^a\)         |
| MCV (fl)                 | 78.6±1.54\(^b\)| 79±1.78          | 85.1±1.92\(^b\)         |
| MCH (pg)                 | 26.4±0.99     | 26.4±0.87         | 25.0±0.84               |
| MCHC (gm/dl)             | 33.2±1.27\(^d\)| 33.5±1.18        | 29.4±0.92\(^b\)         |

Hematocrite (Hct), mean corpuscular volume (mcv), mean corpuscular hemoglobin (mch), and mean corpuscular hemoglobin concentration (mchc). (1) Significantly different from the control at $p \leq 0.01$ (2) Significantly different from the control at $p < 0.05$

### Hematological indices of loaded erythrocytes uptake by endocytosis

Table 2 represents the mean hematological parameters of the Ribavirin loaded erythrocytes obtained with 25mg/ml Ribavirin concentration and values for the same cells before the loading procedures (the control cells) and after loading process but without using drug (sham encapsulated). It was found that the change in hematological parameters is significant at ($p \leq 0.01$).

The hematological parameters, such as MCV, MCH and MCHC were characterized. These parameters determine the influence of the encapsulation process on the hematological properties of the erythrocytes\(^{14}\). The results show changes in hematological parameters were observed at higher concentrations (25mg/ml). From these data, Ribavirin loading into erythrocytes occurs either by encapsulation or binding to the cell membrane\(^1\). Data shows significant changes in MCV in Ribavirin loaded erythrocytes was (85.1±1.92) but sham encapsulated (79±1.78) was similar to control (78.6±1.54).This indicate that the change in loaded erythrocytes is related to the effect of the drug and the loading procedure has no effect. This finding was in agreement with previous report\(^{19}\). There were also slight changes in both MCH and MCHC that appear only in Ribavirin loaded erythrocytes (25.0±0.84 and 29.4±0.92) respectively. These changes can be explained by Ribavirin have minimal oxidative injury of erythrocytes membrane that cause a physical and/or functional barrier of erythrocyte, therefore hemoglobin loss is easier from carrier erythrocytes. This finding was in agreement with Preparation of carrier erythrocytes for RES-targeted delivery of interferon-alpha 2b\(^{21}\). These predictions were supported by the SEM analysis data and osmotic fragility that will discussed later.

### Cell recovery of erythrocytes uptake by Endocytosis method

The percentage ratio of the hematocrite value of the final loaded cells to that of the initial packed cells was 88.42\%. It was determined by hematology analyzer as shown in Table 2. This result was practically better than the recovery results of other studies such as Paclitaxel and Enalapril\(^{22}\).

### Osmotic fragility behavior of Ribavirin loaded erythrocytes by endocytosis

Osmotic fragility determines the susceptibility of erythrocytes to osmotic lysis. The obtained results revealed that there was significant difference in the osmotic fragility of loaded erythrocyte at 25mg/ml Ribavirin when compared to that of unloaded erythrocytes as graphically represented in Figure 2. The osmotic fragility of the studied erythrocytes test is a marker of possible changes in the integrity of the cell membrane caused by the loading procedure.
Moreover, the osmotic fragility test measures the resistance of these cells to changes in the osmotic pressure of the surrounding media. The osmotic fragility test was carried out by using unloaded, sham and Ribavirin loaded erythrocytes. The entrapment of Ribavirin in cells significantly decreases the osmotic fragility of the cells at (p≤ 0.001). And also the osmotic fragility of sham erythrocytes decreased in comparison with unloaded erythrocytes (control). This may be because of the increased mean corpuscular volume of loaded erythrocytes. The obtained results in this part indicate that the erythrocytes resist their hemolysis process in NaCl percent from 0.90 to 0.50% and then the hemolysis of the employed erythrocytes was increased in fluctuation manner till reach 100% when the NaCl percent became 0.00%. These findings were observed for all the tested specimens, i.e., control, sham and Ribavirin loaded erythrocytes. So, at 0.50% NaCl concentration, the osmotic fragility reaches 19.98±1.3%, 19.23±1.7% and 18.50±1.6% absorbance for control sample, sham and Ribavirin loaded erythrocytes, respectively. By decreasing NaCl concentration from 0.45 to 0.00, the osmotic fragility ranges from 48.85±1.8 to 100.00±0.9 for control, ranges from 63.44±2.1 to 100.00±1.0 for sham and ranges from 56.07±1.4 to 100.00±1.0 for Ribavirin loaded erythrocytes. The osmotic fragility of Ribavirin loaded erythrocytes is decreased by increasing NaCl concentration. The obtained correlation coefficients record an inverse proportionality between NaCl concentrations (0.0-0.9%) and the obtained osmotic fragility of Ribavirin loaded erythrocytes, prepared by endocytosis method. The values are -0.908, -0.916 and -0.924 for control (unloaded), sham and Ribavirin loaded erythrocytes, respectively. This may be because of the increased mean corpuscular volume of loaded erythrocytes i.e., the values present in Table 2 showed that the mean corpuscular volume were 78.6±1.54, 79.0±1.78 and 85.1±1.92 for control, sham and Ribavirin loaded erythrocytes, respectively. The osmotic fragility index for normal erythrocytes was found to be 0.486% w/v, for sham was found to be 0.409 % w/v and for loaded erythrocytes was found to be 0.394% w/v. There was a slight decrease in the osmotic fragility index value and was found to be very negligible to be considered. The observed data were in a good agreement with the work done by Madhavi et al., who stated that osmotic fragility of Piperine loaded erythrocytes is decreased compared with that of unloaded cells and sham erythrocytes. The observed results indicate that the osmotic fragility of Ribavirin-loaded erythrocytes are affected by two factors, loading process and Ribavirin as drug cause change in erythrocytes membrane. This result was approved and clearly evidently by scanning electron microscope which be discussed latter in this paper. The accumulation of Ribavirin triphosphate in red blood cells (RBCs). Ribavirin triphosphate accumulation leads to a relative adenosine triphosphate (ATP) deficiency in the RBCs. The associated depletion of its ATP may damage the antioxidant defense system and induce some RBC membrane changes such as oxidative injury, promoting intraerythrocyte oxidative stress with subsequent membrane injury, and that these injured erythrocytes then undergo physiological extravascular destruction by the reticuloendothelial system. This interpretation was supported by other previous studies stated that Ribavirin induce changes in erythrocytes membrane preserve consequently changes in fragility and morphology. The loading process and/or the drug have deleterious effects on erythrocyte shape. The change of carrier cells morphology from the native cells gives the opportunity for carrier erythrocytes to phagocytosed into reticuloendothelial system. This result suggested that loaded erythrocytes can be used for targeting of Ribavirin. This assumption is supported by previous findings which recommended that the use of carrier erythrocytes as targeting system for Piperine due to the distinct effect changes in drug loaded erythrocytes morphology which make drug loaded erythrocytes easily removed by macrophages.
In-vitro release of Ribavirin loaded erythrocytes obtained by endocytosis method

1. In-vitro release in PBS pH 7.4

Figure 3 represents the in-vitro release of Ribavirin from loaded erythrocytes in PBS pH 7.4 over a 20 hrs. An initial burst release was obtained over the first 2 hrs (52.2% from loaded amount of Ribavirin). From the obtained results, there was a rapid release of 52% of Ribavirin within the first 2 hrs indicating that, the drug may be bound on to the surface of the membrane which was released quickly. Then the amount of Ribavirin released increased gradually to reach 88% of the loaded Ribavirin within 20 hrs as observed in Figure 3*. The correlation (r) for zero order, first order and Higuchi diffusion model were found to be 0.8428, 0.8428 and 0.9393 respectively, and after loading there was an increase in the diameter of the erythrocytes around 5µm. The loaded erythrocytes are more enlarged and irregular in shape than biconcave shape with slight damage of the surface. On conclusion there are significant changes in the cell surface and morphology of Ribavirin loaded erythrocytes this may be due to minimal oxidative effect of Ribavirin drug. Fortunately, these membrane integrity changes make Ribavirin loaded erythrocytes much more prone for the phagocytosis by macrophages. The highly changed erythrocyte shape and morphology evidenced in this study, being one of the main determinants in erythrocytes disappearance kinetics in circulation, can be potentially beneficial in terms of successful cell targeting to RES, which, in turn, leads to the improved Ribavirin effects on RES-mediated immune responses and avoidance of deleterious side effects of Ribavirin as hemolytic anemia^7. The changes in SEM pictures current work are in a good agreement with the work done in a previous study^8.

2. In-vitro release in PBS pH 7.4 after treatment with glutaraldehyde

Figure 3 shows the in-vitro release of Ribavirin behavior from loaded erythrocytes by endocytosis in PBS pH 7.4 after using glutaraldehyde as a membrane stabilizer. Figure 3 shows the results of studying the effect of cross-linking agent on the releasing of Ribavirin loaded by endocytosis method. It was clear that the glutaraldehyde reduces the releasing of Ribavirin from Ribavirin loaded erythrocytes, the release after 20 hrs reached 21.77%.

Release kinetics of Ribavirin loaded erythrocytes by endocytosis method

From the obtained releasing data, the coefficient of correlation (r) for zero order, first order and Higuchi diffusion model were found to be 0.8428, 0.8428 and 0.9393 respectively, for the release of Ribavirin Loaded Erythrocytes by endocytosis method and to be 0.9249, 0.3840 and 0.9744 for the release of Ribavirin Loaded Erythrocytes by endocytosis method after adding glutaraldehyde as membrane stabilizer indicating Ribavirin release from loaded erythrocytes undergo diffusion order. Therefore, the efflux of Ribavirin from carrier cells followed diffusion kinetics during the entire experimental period.

Scanning electron microscopy of Ribavirin loaded erythrocytes by endocytosis method

Figure 4 and Figure 5 show the scanning electron micrographs of unloaded erythrocytes and Figure 6 and Figure 7 show Ribavirin loaded erythrocytes by endocytosis method, both at x4300 and x7000 magnification. From the SEM pictures of unloaded (Figure 4 and Figure 5) and Ribavirin loaded erythrocytes (Figure 6 and Figure 7), it's clearly observed that, unloaded normal erythrocytes, the cell surface is smooth and Ribavirin loaded erythrocytes, the cell surface is rough with small lesions. The diameter of the unloaded erythrocytes was around 4µm and after loading there was an increase in the diameter of the erythrocytes around 5µm. The loaded erythrocytes are more enlarged and irregular in shape than biconcave shape with slight damage of the surface. On conclusion there are significant changes in the cell surface and morphology of Ribavirin loaded erythrocytes this may be due to minimal oxidative effect of Ribavirin drug. Fortunately, these membrane integrity changes make Ribavirin loaded erythrocytes much more prone for the phagocytosis by macrophages. The highly changed erythrocyte shape and morphology evidenced in this study, being one of the main determinants in erythrocytes disappearance kinetics in circulation, can be potentially beneficial in terms of successful cell targeting to RES, which, in turn, leads to the improved Ribavirin effects on RES-mediated immune responses and avoidance of deleterious side effects of Ribavirin as hemolytic anemia^7. The changes in SEM pictures current work are in a good agreement with the work done in a previous study^8.

CONCLUSION

The human erythrocytes were loaded successfully with Ribavirin with the practically acceptable loading parameters. The Ribavirin loaded erythrocytes were investigated with respect to their in vitro drug delivery characteristics, including drug release, loading parameters, hematological indices, shape and morphological properties and osmotic fragility. The results of these experiments were indicative of some irreversible changes in cell morphology as well as physiology, which, in turn, may favor the cell targeting to RES organs. The scanning electron micrographs of Ribavirin loaded erythrocytes show significant changes in the cell surface and morphology with rough cell surface and small lesions. This may be due to minimal oxidative effect of Ribavirin drug.
Fortunately, these remarkable membrane integrity changes make Ribavirin loaded erythrocytes much more prone for phagocytosis by macrophages. The considerable changed erythrocyte shape and morphology evidenced in this study, being one of the main determinants in erythrocytes disappearance kinetics in circulation, can be potentially beneficial in terms of successful cell targeting to RES, which in turn leads to the improved Ribavirin effects on RES-mediated immune responses and consequently diminishing of deleterious adverse effects of Ribavirin as hemolytic anemia.
