(Dated: September 26, 2013)

We present the main features of the mathematical theory generated by the $\kappa$-deformed exponential function $\exp_\kappa(x) = (\sqrt{1 + \kappa^2 x^2} + \kappa x)^{1/\kappa}$, with $0 \leq \kappa < 1$, developed in the last twelve years, which turns out to be a continuous one parameter deformation of the ordinary mathematics generated by the Euler exponential function. The $\kappa$-mathematics has its roots in special relativity and furnishes the theoretical foundations of the $\kappa$-statistical mechanics predicting power law tailed statistical distributions which have been observed experimentally in many physical, natural and artificial systems. After introducing the $\kappa$-algebra we present the associated $\kappa$-differential and $\kappa$-integral calculus. Then we obtain the corresponding $\kappa$-exponential and $\kappa$-logarithm functions and give the $\kappa$-version of the main functions of the ordinary mathematics.

I. INTRODUCTION

Undoubtedly the most interesting feature of the statistical distribution function

$$f_i = \exp_\kappa(-\beta E_i + \beta \mu)$$

where the $\kappa$-exponential is defined as

$$\exp_\kappa(x) = (\sqrt{1 + \kappa^2 x^2} + \kappa x)^{1/\kappa}, \quad 0 \leq \kappa < 1,$$

is represented by its asymptotic behavior, namely

$$f_i \sim \exp(-\beta E_i + \beta \mu), \quad f_i \sim N E_i^{1-1/\kappa}.$$

The above $\kappa$-distribution at low energies is the ordinary Boltzmann distribution while at high energies presents a power-law tail. For this reason the statistical theory [1–10], based on the distribution (1.1) has attracted the interest of many researchers.

In the last twelve years various authors have considered the foundations of the statistical theory based on the $\kappa$-distribution, in connection with the historical evolution of the research on the power-law tailed statistical distributions [1][11] e.g. the H-theorem and the molecular chaos hypothesis [12][13], the thermodynamic stability [14][15], the Lesche stability [16][19], the Legendre structure of the ensued thermodynamics [20][21], the thermodynamics of non-equilibrium systems [22], quantum versions of the theory [23][26], the geometrical structure of the theory [22], various mathematical aspects of the theory [28][30], etc. On the other hand specific applications to physical systems have been considered, e.g. the cosmic rays [3], relativistic [37] and classical [38] plasmas in presence of external electromagnetic fields, the relaxation in relativistic plasmas under wave-particle interactions [39][40], anomalous diffusion [41][42], nonlinear kinetics [43][45], kinetics of interacting atoms and photons [46], particle kinetics in the presence of temperature gradients [47][48], particle systems in external conservative force fields [49], stellar distributions in astrophysics [50][53], quark-gluon plasma formation [54], quantum hadrodynamics models [55], the fracture propagation [56], etc. Other applications concern dynamical systems at the edge of chaos [57][59], fractal systems [60], field theories [61], the random matrix theory [62][64], the error theory [65], the game theory [66], the theory of complex networks [67], the information theory [68], etc. Also applications to economic systems have been considered e.g. to study the personal income distribution [69][74], to model deterministic heterogeneity in tastes and product differentiation [75][76], in finance [77][78], in equity options [79], to construct taxation and redistribution models [80], etc.

In this contribution we present the main features of the mathematical theory generated by the function $\exp_\kappa(x)$. The $\kappa$-mathematics, developed in the last twelve years, turns out to be a continuous one parameter deformation of
the ordinary mathematics generated by the Euler exponential function. The \(\kappa\)-mathematics has its roots in special relativity and furnishes the theoretical foundations of the \(\kappa\)-statistical theory predicting power law tailed statistical distributions which have been observed experimentally in many physical, natural and artificial systems.

The paper is organized as follows: After introducing the \(\kappa\)-algebra we present the associated \(\kappa\)-differential and \(\kappa\)-integral calculus. Then we obtain the corresponding \(\kappa\)-generalized exponential and logarithmic functions and give the \(\kappa\)-version of the main functions of the ordinary mathematics.

II. \(\kappa\)-ALGEBRA

**Theorem II.1.** Let be \(x, y \in \mathbb{R}\) and \(-1 < \kappa < 1\). The composition law \(\kappa\)-defined through

\[
x \oplus y = x \sqrt{1 + \kappa^2 y^2} + y \sqrt{1 + \kappa^2 x^2},
\]

(2.1)

is a generalized sum, called \(\kappa\)-sum and the algebraic structure \((\mathbb{R}, \kappa)\) forms an abelian group.

**Proof.** From the definition of \(\kappa\)-the following properties follow
1) associativity: \((x \oplus y) \oplus z = x \oplus (y \oplus z)\),
2) neutral element: \(x \oplus 0 = 0 \oplus x = x\),
3) opposite element: \(x \oplus (−x) = (−x) \oplus x = 0\),
4) commutativity: \(x \oplus y = y \oplus x\).

**Remarks.** The \(\kappa\)-sum is a one parameter continuous deformation of the ordinary sum which recovers in the classical limit \(\kappa \to 0\), i.e. \(x \oplus y = x + y\). The \(\kappa\)-sum (2.1) is the additivity law of the dimensionless relativistic momenta of special relativity while the real parameter \(-1 < \kappa < 1\) is the reciprocal of the dimensionless light speed \([3, 9]\). The \(\kappa\)-difference \(\kappa\) is defined as \(x \ominus y = x \oplus (−y)\).

**Theorem II.2.** Let be \(x, y \in \mathbb{R}\) and \(-1 < \kappa < 1\). The composition law \(\kappa\)-defined through

\[
x \otimes y = \frac{1}{\kappa} \sinh \left( \frac{1}{\kappa} \arcsinh (\kappa x) \arcsinh (\kappa y) \right),
\]

(2.2)

is a generalized product, called \(\kappa\)-product and the algebraic structure \((\mathbb{R}, \kappa)\) forms an abelian group.

**Proof.** From the definition of \(\kappa\)-the following properties follow
1) associativity: \((x \otimes y) \otimes z = x \otimes (y \otimes z)\),
2) neutral element: is defined through \(x \otimes I = I \otimes x = x\) and is given by \(I = \kappa^{-1} \sinh \kappa\),
3) inverse element: is defined through \(x \otimes \overline{x} = I \otimes x = I\) and is given by \(\overline{x} = \kappa^{-1} \sinh(\kappa^2/\arcsinh \kappa x)\),
4) commutativity: \(x \otimes y = y \otimes x\).

**Remarks.** The \(\kappa\)-product reduces to the ordinary product as \(\kappa \to 0\), i.e. \(x \otimes y = xy\). The \(\kappa\)-division \(\kappa\) is defined through \(x \odot y = x \otimes \overline{y}\).

**Theorem II.3.** Let be \(x, y \in \mathbb{R}\) and \(-1 < \kappa < 1\). The \(\kappa\)-sum \(\kappa\)-defined in (2.1), and the \(\kappa\)-product \(\kappa\)-defined in (2.2), obey the distributive law

\[
z \otimes (x \oplus y) = (z \otimes x) \oplus (z \otimes y),
\]

(2.3)

and then the algebraic structure \((\mathbb{R}, \oplus, \otimes)\) forms an abelian field.

**Proof.** The relationship (2.3) follows directly from the definitions of the \(\kappa\)-product (2.2) and of the \(\kappa\)-sum (2.1) which can be written also in the form

\[
x \oplus y = \frac{1}{\kappa} \sinh \left( \arcsinh (\kappa x) + \arcsinh (\kappa y) \right).
\]

(2.4)

**Theorem II.4.** The abelian fields \((\mathbb{R}, \oplus, \otimes)\) and \((\mathbb{R}, +, \cdot)\) are isomorphic.

**Proof.** After introducing the function \(\{x\} \in C^\infty(\mathbb{R})\) through

\[
\{x\} = \frac{1}{\kappa} \arcsinh (\kappa x),
\]

(2.5)
whose inverse function \([x] \in C^\infty(\mathbb{R})\), i.e. \([\{x\}] = \{[x]\} = x\), is given by
\[
[x] = \frac{1}{\kappa} \sinh (\kappa x) ,
\] (2.6)
we can write Eqs. (2.4) and (2.2) in the form
\[
\{x \oplus y\} = \{x\} + \{y\} ,
\]
(2.7)
\[
\{x \otimes y\} = \{x\} \cdot \{y\} ,
\]
(2.8)
or equivalently as
\[
[x] \oplus [y] = [x + y] ,
\]
(2.9)
\[
[x] \otimes [y] = [x \cdot y] .
\]
(2.10)

**Theorem II.5.** Let be \(x \in \mathbb{R}\) and \(n\) an arbitrary nonnegative integer. It holds
\[
\underbrace{x \oplus x \oplus \ldots \oplus x}_n \otimes x = [n] \otimes x .
\]
(2.11)

**Proof.** The function \([x]\) and its inverse \(\{x\}\) obey the condition \([\{x\}] = \{[x]\} = x\). Furthermore we take into account (2.7) and (2.10). Then we have
\[
x \oplus x \oplus \ldots \oplus x = [\{x \oplus x \oplus \ldots \oplus [x]\}]
= [\{x\} + \{x\} + \ldots + \{x\}]
= [n \cdot \{x\}]
= [\{(n)\} \cdot \{x\}]
= [n] \otimes [x]
= [n] \otimes x .
\]

**III. \(\kappa\)-DIFFERENTIAL CALCULUS**

**A. \(\kappa\)-Differential**

The \(\kappa\)-differential of \(x\), indicated by \(d_\kappa x\), is defined through
\[
(x + dx) \oplus x = d_\kappa x + 0((dx)^2) ,
\]
(3.1)
and results to be
\[
\frac{d_\kappa x}{\gamma(x)} = \frac{dx}{\sqrt{1 + \kappa^2 x^2}} .
\]
(3.2)

In order to better understand the origin of the expression of \(d_\kappa x\) we recall that the variable \(x\) is a dimensionless momentum. Then the quantity \(\gamma(x) = \sqrt{1 + \kappa^2 x^2}\) is the Lorentz factor of relativistic physics, in the momentum representation. So, we can write
\[
\frac{d_\kappa x}{\gamma(x)} = \frac{dx}{\gamma(x)} .
\]
(3.3)

Moreover it holds
\[
d_\kappa x = d\{x\} = \frac{d\{x\}}{dx} dx .
\]
(3.4)
B. $\kappa$-Derivative

We define the $\kappa$-derivative of the function $f(x)$ through

$$\frac{df(x)}{d\kappa x} = \lim_{z \to x} \frac{f(z) - f(x)}{z \ominus x} \approx \lim_{dx \to 0} \frac{f(x + dx) - f(x)}{(x + dx) \ominus x}.$$  \hspace{1cm} (3.5)

We observe that $df(x)/d\kappa x$, which reduces to $df(x)/dx$ as the deformation parameter $\kappa \to 0$, can be written in the form

$$\frac{df(x)}{d\kappa x} = \sqrt{1 + \kappa^2 x^2} \frac{df(x)}{dx}.$$  \hspace{1cm} (3.6)

From the latter relationship follows that the $\kappa$-derivative obeys the Leibniz’s rules of the ordinary derivative. After introducing the $\gamma(x)$ Lorentz factor the $\kappa$-derivative can be written also in the form:

$$\frac{d}{d\kappa x} = \gamma(x) \frac{d}{dx}.$$  \hspace{1cm} (3.7)

C. $\kappa$-Integral

We define the $\kappa$-integral as the inverse operator of the $\kappa$-derivative through

$$\int d\kappa x \ f(x) = \int \frac{dx}{\sqrt{1 + \kappa^2 x^2}} \ f(x),$$  \hspace{1cm} (3.8)

and note that it is governed by the same rules of the ordinary integral, which recovers when $\kappa \to 0$.

D. Connections with Physics

We indicate with $p = |p|$ and $x = p/mv$, the moduli of the particle momentum in dimensional and dimensionless form respectively and define $\kappa = v/c$. The classical relationship linking $x$ with the dimensionless kinetic energy $W = x^2/2$ follows from the kinetic energy theorem, which in differential form reads

$$\frac{d}{dx} W = x.$$  \hspace{1cm} (3.9)

The latter equation after replacing the ordinary derivative by the derivative $d/d\kappa x$, i.e.

$$\frac{d}{d\kappa x} W = x,$$  \hspace{1cm} (3.10)

transforms into the corresponding relativistic equation. This differential equation with the condition $W(x = 0) = 0$ admits as unique solution $W = (\sqrt{1 + \kappa^2 x^2} - 1)/\kappa^2$ defining the relativistic kinetic energy.

Let us consider the four-dimensional Lorentz invariant integral

$$I = \int d^4p \ \theta(p_0) \ \delta(p^\mu p_\mu - m^2 c^2) \ F(p),$$  \hspace{1cm} (3.11)

being $p^\mu = (p^0, \mathbf{p}) = \left(\sqrt{m^2 c^2 + p^2}, \mathbf{p}\right)$, $\theta(.)$ the Heaviside step function and $\delta(.)$ the Dirac delta function. It is trivial to verify that the latter integral transforms into the one-dimension integral

$$I \propto \int d\kappa x \ f(x),$$  \hspace{1cm} (3.12)

being $f(x) = 4\pi x^2 F(x)$. Then the $\kappa$-integral is essentially the Lorentz invariant integral of special relativity.
IV. THE FUNCTION $\exp_\kappa(x)$

A. Definition

We recall that the ordinary exponential $f(x) = \exp(x)$ emerges as solution both of the functional equation $f(x+y) = f(x)f(y)$ and of the differential equation $(d/dx)f(x) = f(x)$. The question to determine the solution of the generalized equations

$$f(x \oplus y) = f(x)f(y), \quad (4.1)$$

$$\frac{d f(x)}{d_\kappa x} = f(x), \quad (4.2)$$

reducing in the $\kappa \to 0$ limit to the ordinary exponential, naturally arises. This solution is unique and represents a one-parameter generalization of the ordinary exponential.

Solution of Eq. $(4.1)$: We write this equation explicitly

$$f \left( x\sqrt{1+\kappa^2 y^2} + y\sqrt{1+\kappa^2 x^2} \right) = f(x)f(y), \quad (4.3)$$

which after performing the change of variables $f(x) = \exp(g(\kappa x))$, $z_1 = \kappa x$, $z_2 = \kappa y$ transforms as

$$g \left( z_1\sqrt{1+z_2^2} + z_2\sqrt{1+z_1^2} \right) = g(z_1) + g(z_2), \quad (4.4)$$

and admits as solution $g(x) = A\arcsinh x$. Then it results that $f(x) = \exp(A\arcsinh \kappa x)$. The arbitrary constant $A$ can be fixed through the condition $\lim_{\kappa \to 0} f(x) = \exp(x)$, obtaining $A = 1/\kappa$. Therefore $f(x) = \exp_\kappa(x)$ being

$$\exp_\kappa(x) = \exp \left( \frac{1}{\kappa} \arcsinh \kappa x \right). \quad (4.5)$$

Solution of Eq. $(4.2)$: According to Eq. $(4.2)$ the function $f(x) = \exp_\kappa(x)$ is defined as eigenfunction of $d/d_\kappa x$ i.e.

$$\frac{d \exp_\kappa(x)}{d_\kappa x} = \exp_\kappa(x). \quad (4.6)$$

After recalling that $d_\kappa x = d\{x\}$ with $\{x\} = \kappa^{-1} \arcsinh \kappa x$, Eq. $(4.6)$ can be written in the form

$$\frac{d \exp_\kappa(x)}{d\{x\}} = \exp_\kappa(x). \quad (4.7)$$

The solution of the latter equation with the condition $\exp_\kappa(0) = 1$ follows immediately

$$\exp_\kappa(x) = \exp (\{x\}). \quad (4.8)$$

After taking into account that $\arcsinh x = \ln(\sqrt{1+x^2} + x)$ we can write $\exp_\kappa(x)$ in the form

$$\exp_\kappa(x) = \left( \sqrt{1+\kappa^2 x^2} + \kappa x \right)^{1/\kappa}, \quad (4.9)$$

which will used in the following. We remark that $\exp_\kappa(x)$ given by Eq. $(4.9)$, is solution both of the Eqs. $(4.1)$ and $(4.2)$ and therefore represents a generalization of the ordinary exponential.

B. Basic Properties

From the definition $(4.9)$ of $\exp_\kappa(x)$ follows that

$$\exp_0(x) \equiv \lim_{\kappa \to 0} \exp_\kappa(x) = \exp(x), \quad (4.10)$$

$$\exp_{-\kappa}(x) = \exp_\kappa(x). \quad (4.11)$$
Like the ordinary exponential, $\exp_\kappa(x)$ has the properties

$$\exp_\kappa(x) \in C^\infty(\mathbb{R}), \quad (4.12)$$

$$\frac{d}{dx} \exp_\kappa(x) > 0, \quad (4.13)$$

$$\exp_\kappa(-\infty) = 0^+, \quad (4.14)$$

$$\exp_\kappa(0) = 1, \quad (4.15)$$

$$\exp_\kappa(+\infty) = +\infty, \quad (4.16)$$

$$\exp_\kappa(x) \exp_\kappa(-x) = 1. \quad (4.17)$$

In Fig. 1 is plotted the function $\exp_\kappa(x)$ defined in Eq. (4.9) for three different values of the parameter of $\kappa$. The continuous curve corresponding to $\kappa = 0$ is the ordinary exponential function $\exp(x)$.

![Graph of $\exp_\kappa(x)$](image)

FIG. 1: Plot of the function $\exp_\kappa(x)$ defined in Eq. (4.9) for three different values of the parameter of $\kappa$. The continuous curve corresponding to $\kappa = 0$ is the ordinary exponential function $\exp(x)$.

The property (4.17) emerges as particular case of the more general one

$$\exp_\kappa(x) \exp_\kappa(y) = \exp_\kappa(x \oplus y). \quad (4.18)$$

Furthermore $\exp_\kappa(x)$ has the property

$$(\exp_\kappa(x))^r = \exp_{\kappa/r}(rx), \quad (4.19)$$

with $r \in \mathbb{R}$, which in the limit $\kappa \to 0$ reproduces one well known property of the ordinary exponential.

We remark the following convexity property

$$\frac{d^2}{dx^2} \exp_\kappa(x) > 0; \quad x \in \mathbb{R}, \quad (4.20)$$

holding when $\kappa^2 < 1$.

Undoubtedly one of the more interesting properties of $\exp_\kappa(x)$ is its power law asymptotic behavior

$$\exp_\kappa(x) \underset{x \to \pm \infty}{\sim} |2\kappa x|^{\pm 1/|\kappa|}. \quad (4.21)$$
C. Mellin transform

Let us consider the incomplete Mellin transform of the \( \exp_\kappa(-t) \)

\[
\mathcal{M}_\kappa(r, x) = \int_0^x t^{r-1} \exp_\kappa(-t) \, dt .
\]  

(4.22)

After performing the change of integration variable \( y = (\sqrt{1 + \kappa^2 t^2} - |\kappa| t)^2 \), and after taking into account that \( t = \frac{1}{2|\kappa|} (y^{-1/2} - y^{1/2}) \) and \( \exp_\kappa(-t) = y^{1/2|\kappa|} \), the function \( \mathcal{M}_\kappa(r, x) \) can be written in the form

\[
\mathcal{M}_\kappa(r, x) = \frac{1}{2} |2\kappa|^{-r} \int_0^x y^{\frac{1}{2|\kappa|}-\frac{r}{2}} - \frac{(1-y)^{r-1} (1+y)}{2} \, dy .
\]  

(4.23)

with

\[
X = \left( \sqrt{1 + \kappa^2 x^2} - |\kappa|x \right)^2 .
\]  

(4.24)

When \( r \) is an integer greater than zero, \( \mathcal{M}_\kappa(r, x) \) can be calculated analytically. For instance it results

\[
\mathcal{M}_\kappa(1, x) = \frac{1}{1 - \kappa^2} - \frac{\kappa^2 x + \sqrt{1 + \kappa^2 x^2}}{1 - \kappa^2} \exp_\kappa(-x) ,
\]  

(4.25)

\[
\mathcal{M}_\kappa(2, x) = \frac{1}{1 - 4\kappa^2} - \frac{1 + 2\kappa^2 x^2 + x \sqrt{1 + \kappa^2 x^2}}{1 - 4\kappa^2} \exp_\kappa(-x) .
\]  

(4.26)

In general the function \( \mathcal{M}_\kappa(r, x) \) can be written as

\[
\mathcal{M}_\kappa(r, x) = \frac{1}{2} |2\kappa|^{-r} \left[ I_1(r) - I_X(r) \right] ,
\]  

(4.27)

with

\[
I_X(r) = \int_0^X y^{\frac{1}{2|\kappa|}-\frac{r}{2}} - \frac{(1-y)^{r-1} (1+y)}{2} \, dy + \int_0^X y^{\frac{1}{2|\kappa|}-\frac{r}{2}} - \frac{(1-y)^{r-1} (1+y)}{2} \, dy .
\]  

(4.28)

After recalling the definition of the Beta incomplete function \( B_X(s, r) = \int_0^X y^{s-1} (1-y)^{r-1} \, dy \), the integral \( I_X(r) \) becomes

\[
I_X(r) = B_X \left( \frac{1}{2|\kappa|} - \frac{r}{2} , r \right) + B_X \left( \frac{1}{2|\kappa|} - \frac{r}{2} + 1 , r \right) .
\]  

(4.29)

The function \( I_1(r) \) can be expressed in term of the Beta functions \( B(s, r) = \int_0^1 y^{s-1} (1-y)^{r-1} \, dy \), and then in terms of Gamma functions, obtaining

\[
I_1(r) = \frac{2 \Gamma(r)}{1 + |\kappa|r} \frac{\Gamma \left( \frac{1}{2|\kappa|} - \frac{r}{2} \right)}{\Gamma \left( \frac{1}{2|\kappa|} + \frac{r}{2} \right)} .
\]  

(4.30)

Finally the incomplete Mellin transform \( \mathcal{M}_\kappa(r, x) \) of \( \exp_\kappa(-t) \) assumes the form

\[
\mathcal{M}_\kappa(r, x) = \frac{|2\kappa|^{-r} \Gamma \left( \frac{1}{2|\kappa|} - \frac{r}{2} \right)}{\Gamma \left( \frac{1}{2|\kappa|} + \frac{r}{2} \right)} \Gamma(r)
\]

\[ - \frac{1}{2} |2\kappa|^{-r} B_X \left( \frac{1}{2|\kappa|} - \frac{r}{2} , r \right) \]

\[ - \frac{1}{2} |2\kappa|^{-r} B_X \left( \frac{1}{2|\kappa|} - \frac{r}{2} + 1 , r \right) .
\]  

(4.31)
The Mellin transform of $\exp_{\kappa}(-t)$, namely

$$\mathcal{M}_{\kappa}(r) = \int_0^\infty t^{r-1} \exp_{\kappa}(-t) \, dt \ ,$$

(4.32)

can be calculated from Eq. (4.31) by posing $x = \infty$. The explicit expression of $\mathcal{M}_{\kappa}(r)$ holding for $0 < r < 1/|\kappa|$ is given by

$$\mathcal{M}_{\kappa}(r) = \frac{|2\kappa|^{-r}}{1 + |\kappa|^r} \frac{\Gamma \left( \frac{1}{2|\kappa|} - \frac{r}{2} \right)}{\Gamma \left( \frac{1}{2|\kappa|} + \frac{r}{2} \right)} \Gamma (r) \ .$$

(4.33)

From the latter relationship one can verify easily the property

$$\mathcal{M}_{\kappa}(r + 2) = \frac{r(r + 1)}{1 - \kappa^2 (r + 2)^2} \mathcal{M}_{\kappa}(r) \ .$$

(4.34)

D. Taylor expansion

The Taylor expansion of $\exp_{\kappa}(x)$ given in [3] can be written also in the following form

$$\exp_{\kappa}(x) = \sum_{n=0}^{\infty} \frac{x^n}{n!_{\kappa}} \ ; \ \kappa^2 x^2 < 1 \ ,$$

(4.35)

where the symbol $n!_{\kappa}$, representing the $\kappa$-generalization of the ordinary factorial $n!$, recovered for $\kappa = 0$, is given by

$$n!_{\kappa} = \frac{n!}{\xi_n(\kappa)} \ ,$$

(4.36)

and the polynomials $\xi_n(\kappa)$ are defined as

$$\xi_0(\kappa) = \xi_1(\kappa) = 1 \ ,$$

(4.37)

$$\xi_n(\kappa) = \prod_{j=1}^{n-1} \left[ 1 - (2j - n) \kappa \right] \ ; \ n > 1 \ .$$

(4.38)

The polynomials $\xi_n(\kappa)$, for $n > 1$, when $n$ is odd, are of degree $n - 1$, with respect the variable $\kappa$, while when $n$ is even the degree of $\xi_n(\kappa)$ is $n - 2$. The degree of $\xi_n(\kappa)$ is always an even number and it results

$$\xi_{2m}(\kappa) = \prod_{j=0}^{m-1} \left[ 1 - (2j)^2 \kappa^2 \right] \ ; \ m > 0 \ ,$$

(4.39)

$$\xi_{2m+1}(\kappa) = \prod_{j=0}^{m-1} \left[ 1 - (2j + 1)^2 \kappa^2 \right] \ ; \ m > 0 \ .$$

(4.40)

The polynomials $\xi_n(\kappa)$ can be generated by the following simple recursive formula

$$\xi_0(\kappa) = \xi_1(\kappa) = 1 \ ,$$

(4.41)

$$\xi_{n+2}(\kappa) = (1 - n^2 \kappa^2) \xi_n(\kappa) \ ; \ n \geq 0 \ .$$

(4.42)

The first nine polynomials reads as

$$\xi_0(\kappa) = \xi_1(\kappa) = \xi_2(\kappa) = 1 \ ,$$

(4.43)

$$\xi_3(\kappa) = 1 - \kappa^2 \ ,$$

(4.44)

$$\xi_4(\kappa) = 1 - 4\kappa^2 \ ,$$

(4.45)

$$\xi_5(\kappa) = (1 - \kappa^2)(1 - 9\kappa^2) \ ,$$

(4.46)

$$\xi_6(\kappa) = (1 - 4\kappa^2)(1 - 16\kappa^2) \ ,$$

(4.47)

$$\xi_7(\kappa) = (1 - \kappa^2)(1 - 9\kappa^2)(1 - 25\kappa^2) \ ,$$

(4.48)

$$\xi_8(\kappa) = (1 - 4\kappa^2)(1 - 16\kappa^2)(1 - 36\kappa^2) \ .$$

(4.49)
After noting that for a given value of $\kappa$ the maximum natural number $N$ satisfying the condition $N < 2 + 1/|\kappa|$ is defined univocally, we can verify easily that for $n = 0, 1, 2, ..., N$ it results $\xi_n(\kappa) > 0$ and then $n!_\kappa > 0$. For $n > N$ the sign of $\xi_n(\kappa)$ and then of $n!_\kappa$ alternates with periodicity $- - + + - - + ...$.

From Eqs. (4.39) and (4.52) follows the recursive formula

$$
(n + 2)!_\kappa = \frac{(n + 1)(n + 2)}{1 - n^2\kappa^2} \cdot n!_\kappa .
$$

(4.50)

By direct comparison of Eq. (4.34) and (4.50) we obtain the relationship

$$
n!_\kappa = (1 - \kappa^2 n^2) \frac{1}{n} \int_0^\infty t^{n-1} \exp_\kappa(-t) \, dt .
$$

(4.51)

It is remarkable that the first three terms in the Taylor expansion of $\exp_\kappa(x)$ are the same of the ordinary exponential

$$
\exp_\kappa(x) = 1 + x + \frac{x^2}{2} + (1 - \kappa^2) \frac{x^3}{3!} + ... .
$$

(4.52)

E. The function $\Gamma_\kappa(x)$

The $\Gamma_\kappa(n)$ with $n$ integer is defined through

$$
\Gamma_\kappa(n) = (n - 1)!_\kappa ,
$$

(4.53)

and represents a generalization of the Euler $\Gamma(n)$ function. In particular we have $\Gamma_\kappa(1) = \Gamma_\kappa(2) = 1$ and $\Gamma_\kappa(3) = 2$. This definition and the relationship (4.51) suggests the following one parameter generalization of the Euler $\Gamma(x)$ function i.e. $\Gamma_\kappa(x)$, given by

$$
\Gamma_\kappa(x) = \left[1 - \kappa^2(x - 1)^2\right] (x - 1) \int_0^\infty t^{x-2} \exp_\kappa(-t) \, dt .
$$

(4.54)

The explicit expression of $\Gamma_\kappa(x)$ in terms of the ordinary $\Gamma(x)$ is given by

$$
\Gamma_\kappa(x) = \frac{1 - |\kappa|(x - 1)}{2|\kappa|x - 1} \frac{\Gamma\left(\frac{1}{|2\kappa|} - \frac{x - 1}{2}\right)}{\Gamma\left(\frac{1}{|2\kappa|} + \frac{x - 1}{2}\right)} \Gamma(x) ,
$$

(4.55)

and can be used as definition of $\Gamma_\kappa(x)$ when $x$ is a complex variable. Clearly in the $\kappa \to 0$ limit it results $\Gamma_0(x) = \Gamma(x)$. An expression of $\Gamma_\kappa(x)$ in terms of the Beta function is the following

$$
\Gamma_\kappa(x) = \frac{1 - |\kappa|(x - 1)}{2|\kappa|x - 1} (x - 1) B\left(\frac{1}{|2\kappa|} - \frac{x - 1}{2}, x - 1\right) .
$$

(4.56)

From Eqs. (4.34) and (4.55) follows the property

$$
\Gamma_\kappa(x + 2) = \frac{x(x + 1)}{1 - \kappa^2(x - 1)^2} \Gamma_\kappa(x) .
$$

(4.57)

The Taylor expansion of $\exp_\kappa(x)$ can be written also in the form

$$
\exp_\kappa(x) = \sum_{n=0}^\infty \frac{x^n}{\Gamma_\kappa(n + 1)} ; \quad \kappa^2 x^2 < 1 .
$$

(4.58)

In Fig.2 and Fig.3 is plotted the function $\Gamma_\kappa(x)$ defined in Eq. (4.56) in the ranges $-4 < x < 4$ and $9 < x < 12$ respectively, for $\kappa = 0$ and $\kappa = 0.15$. The continuous curve corresponding to $\kappa = 0$ is the ordinary Gamma function $\Gamma(x)$.

The incomplete $\gamma_\kappa(r, x)$ and $\Gamma_\kappa(r, x)$ are defined as

$$
\gamma_\kappa(r, x) = \left[1 - \kappa^2(r - 1)^2\right] (r - 1) \int_0^x t^{r-2} \exp_\kappa(-t) \, dt ,
$$

(4.59)

$$
\Gamma_\kappa(r, x) = \left[1 - \kappa^2(r - 1)^2\right] (r - 1) \int_x^\infty t^{r-2} \exp_\kappa(-t) \, dt ,
$$

(4.60)
and hold the following relationships
\[
\gamma_\kappa(r, x) + \Gamma_\kappa(r, x) = \Gamma_\kappa(r) \quad , \\
\gamma_\kappa(r, \infty) = \Gamma_\kappa(r) \quad , \\
\gamma_\kappa(r, x) = (r-1)[1-\kappa^2(r-1)^2] \mathcal{M}_\kappa(r-1, x) \quad .
\]

F. Expansion in ordinary exponentials

Starting from the expression (4.5) \(\exp_\kappa(x)\) and the Taylor expansion of the function \(\text{arcsinh}(x)\) we obtain
\[
\exp_\kappa(x) = \exp \left( \sum_{n=0}^{\infty} c_n \kappa^{2n} x^{2n+1} \right) \quad , \quad \kappa^2 x^2 \leq 1 \quad ,
\]
with
\[
c_n = \frac{(-1)^n (2n)!}{(2n+1) 2^{2n} (n!)^2} \quad .
\]

Exploiting this relationship, we can write \(\exp_\kappa(x)\) as an infinite product of ordinary exponentials
\[
\exp_\kappa(x) = \prod_{n=0}^{\infty} \exp \left( c_n \kappa^{2n} x^{2n+1} \right) \quad .
\]

On the other hand \(\exp_\kappa(x)\) can be viewed as a continuous linear combination of an infinity of standard exponentials. Namely for \(\text{Re}\, s \geq 0\), it holds the following Laplace transform
\[
\exp_\kappa(-s) = \int_0^{\infty} \frac{1}{\kappa x} J_{\kappa}(\frac{x}{\kappa}) \exp(-sx) \, dx \quad ,
\]
being \(J_\nu(x)\) the Bessel function.
FIG. 3: Plot of the function $\Gamma_\kappa(x)$ defined in Eq.(4.55) in the range $9 < x < 12$ for $\kappa = 0$ and $\kappa = 0.15$. The continuous curve corresponding to $\kappa = 0$ is the ordinary Gamma function $\Gamma(x)$.

G. $\kappa$-Laplace transform

The following $\kappa$-Laplace transform emerges naturally

$$F_\kappa(s) = \mathcal{L}_\kappa \{ f(t) \}(s) = \int_0^\infty f(t) [\exp_\kappa(-t)]^s \, dt ,$$

as a generalization of the ordinary Laplace transform. The inverse $\kappa$-Laplace transform is given by

$$f(t) = \mathcal{L}_\kappa^{-1} \{ F_\kappa(s) \}(t) = \frac{1}{2\pi i} \int_{c-i\infty}^{c+i\infty} F_\kappa(s) \frac{[\exp_\kappa(t)]^s}{\sqrt{1 + \kappa^2 t^2}} \, ds .$$

In ref. [34] the mathematical properties of the $\kappa$-Laplace transform have been investigated systematically. In table I are reported the main properties of the $\kappa$-Laplace transform which in the $\kappa \to 0$ limit reduce to the corresponding ordinary Laplace transform properties.

Furthermore it holds the initial value theorem

$$\lim_{t \to 0} f(t) = \lim_{s \to \infty} sF_\kappa(s) ,$$

and the final value theorem

$$\lim_{t \to \infty} |\kappa| tf(t) = \lim_{s \to 0} sF_\kappa(s) .$$

The $\kappa$-convolution of two functions $f \ast_\kappa g = (f \ast_\kappa g)(t)$, is defined as

$$f \ast_\kappa g = \int_0^t f(t \ominus \tau) g(\tau) \frac{1 - \kappa^2 \tau(t - \tau)}{\sqrt{1 + \kappa^2 \tau^2}} \, d\tau .$$

and has the following properties

$$f \ast_\kappa (ag + bh) = a(f \ast_\kappa g) + b(f \ast_\kappa h) ,$$

$$f \ast_\kappa g = g \ast_\kappa f ,$$

$$f \ast_\kappa (g \ast_\kappa h) = (f \ast_\kappa g) \ast_\kappa h .$$
| $f(t)$ | $F_\kappa(s)$ |
|--------|--------------|
| $a f(t) + b g(t)$ | $a F_\kappa(s) + b G_\kappa(s)$ |
| $f(at)$ | $\frac{1}{a} F_{\kappa/a}(\frac{s}{a})$ |
| $f(t) [\exp_\kappa(-t)]^a$ | $F_\kappa(s-a)$ |
| $\frac{d f(t)}{dt}$ | $s \mathcal{L}_\kappa \left\{ \frac{f(t)}{\sqrt{1 + \kappa^2 t^2}} \right\} (s) - f(0)$ |
| $\frac{d^2}{ds^2} \sqrt{1 + \kappa^2 t^2} f(t)$ | $s F_\kappa(s) - f(0)$ |
| $\frac{1}{\sqrt{1 + \kappa^2 t^2}} \int_0^t f(w)dw$ | $\frac{1}{2} F_\kappa(s)$ |
| $f(t) [\ln(\exp_\kappa(t))]^n$ | $(-1)^n \frac{d^n F_\kappa(s)}{ds^n}$ |
| $f(t) [\ln(\exp_\kappa(t))]^{-n}$ | $\int_s^{+\infty} dw_n \int_{w_n}^{+\infty} dw_{n-1} \cdots \int_{w_3}^{+\infty} dw_2 \int_{w_2}^{+\infty} dw_1 F_\kappa(w_1)$ |

It holds the following $\kappa$-convolution theorem

$$\mathcal{L}_\kappa \{ f \ast g \} = \mathcal{L}_\kappa \{ f \} \mathcal{L}_\kappa \{ g \} .$$ \hfill (4.76)

In Table II are reported the $\kappa$-Laplace transforms for the delta function, for the unit function and for the power function. We note that $\kappa$-Laplace transform of the power function $f(t) = t^{\nu-1}$ involves the $\kappa$-generalized Gamma function. All the $\kappa$-Laplace transforms in the $\kappa \to 0$ limit reduce to the corresponding ordinary Laplace transforms.

V. THE FUNCTION $\ln_\kappa(x)$

A. Definition and basic properties

The function $\ln_\kappa(x)$ is defined as the inverse function of $\exp_\kappa(x)$, namely

$$\ln_\kappa(\exp_\kappa x) = \exp_\kappa(\ln_\kappa x) = x ,$$ \hfill (5.1)

and is given by

$$\ln_\kappa(x) = [\ln x] ,$$ \hfill (5.2)

and then

$$\ln_\kappa(x) = \frac{1}{\kappa} \sinh (\kappa \ln x) ,$$ \hfill (5.3)
| $f(t)$ | $F_\kappa(s)$ |
|--------|---------------|
| $\delta(t - \tau)$ | $[\exp_\kappa(-\tau)]^s$ |
| $u(t - \tau)$ | $\frac{\sqrt{1 + \kappa^2 \tau^2 + \kappa^2 s}}{s^2 - \kappa^2 \nu} [\exp_\kappa(-\tau)]^s$ |
| $t^{\nu - 1}$ | $\frac{\Gamma(\nu + 1)}{\nu s^\nu} = \frac{\Gamma(\nu)}{s^\nu |\kappa|^{\nu}} \frac{\Gamma\left(\frac{1}{\nu - 1}\right)}{\Gamma\left(\frac{\nu}{\nu - 1}\right)}$ |
| $t^{2m - 1}$, $m \in \mathbb{Z}^+$ | $\prod_{j=1}^{(2m-1)} \left[ s^2 - (2j - 1)^2 \kappa^2 \right]$ |
| $t^{2m}$, $m \in \mathbb{Z}^+$ | $\prod_{j=1}^{(2m)} \left[ s^2 - (2j - 1)^2 \kappa^2 \right]$ |

or more properly

$$\ln_\kappa(x) = \frac{x^\kappa - x^{-\kappa}}{2\kappa} . \quad (5.4)$$

It results that

$$\ln_0(x) \equiv \lim_{\kappa \to 0} \ln_\kappa(x) = \ln(x) \quad (5.5)$$

$$\ln_{-\kappa}(x) = \ln_\kappa(x) \quad (5.6)$$

The function $\ln_\kappa(x)$, just as the ordinary logarithm, has the properties

$$\ln_\kappa(x) \in C^\infty(\mathbb{R}^+), \quad (5.7)$$

$$\frac{d}{dx} \ln_\kappa(x) > 0, \quad (5.8)$$

$$\ln_\kappa(0^+) = -\infty, \quad (5.9)$$

$$\ln_\kappa(1) = 0, \quad (5.10)$$

$$\ln_\kappa(+\infty) = +\infty, \quad (5.11)$$

$$\ln_\kappa(1/x) = -\ln_\kappa(x) . \quad (5.12)$$

In Fig.1 is plotted the function $\ln_\kappa(x)$ defined in Eq.(5.4) for three different values of the parameter of $\kappa$. The continuous curve corresponding to $\kappa = 0$ is the ordinary logarithm function $\ln(x)$.

Furthermore $\ln_\kappa(x)$ has the two properties

$$\ln_\kappa(x^r) = r \ln_\kappa(x) \quad (5.13)$$

$$\ln_\kappa(xy) = \ln_\kappa(x) \frac{\kappa}{\nu} \ln_\kappa(y) \quad (5.14)$$

with $r \in \mathbb{R}$. Note that the property (5.12) follows as particular case of the property (5.14).

We remark the following concavity properties

$$\frac{d^2}{dx^2} \ln_\kappa(x) < 0 , \quad (5.15)$$

$$\frac{d^2}{dx^2} x \ln_\kappa(x) < 0 . \quad (5.16)$$
FIG. 4: Plot of the function \( \ln_\kappa(x) \) defined by Eq. (5.4) for three different values of the parameter \( \kappa \). The continuous curve corresponding to \( \kappa = 0 \) is the ordinary logarithm function \( \ln(x) \).

A very interesting property of this function is its power law asymptotic behavior

\[
\ln_\kappa(x) \sim x \to 0^+ - \frac{1}{2 |\kappa|} x^{-|\kappa|},
\]

(5.17)

\[
\ln_\kappa(x) \sim x \to +\infty \frac{1}{2 |\kappa|} |x|^{|\kappa|}.
\]

(5.18)

After recalling the integral representation of the ordinary logarithm

\[
\ln(x) = \frac{1}{2} \int_{1/x}^x \frac{1}{t} dt,
\]

(5.19)

one can verify that the latter relationship can be generalized easily in order to obtain \( \ln_\kappa(x) \), by replacing the integrand function \( y_0(t) = t^{-1} \) by the new function \( y_\kappa(t) = t^{-1-\kappa} \), namely

\[
\ln_\kappa(x) = \frac{1}{2} \int_{1/x}^x \frac{1}{t^{1+\kappa}} dt.
\]

(5.20)

B. Taylor expansion

The Taylor expansion of \( \ln_\kappa(1 + x) \) converges if \( -1 < x \leq 1 \), and assumes the form

\[
\ln_\kappa(1 + x) = \sum_{n=1}^{\infty} b_n(\kappa) (-1)^{n-1} \frac{x^n}{n},
\]

(5.21)

with \( b_1(\kappa) = 1 \), while for \( n > 1 \), \( b_n(\kappa) \) is given by

\[
b_n(\kappa) = \frac{1}{2} \left( 1 - \kappa \right) \left( 1 - \frac{\kappa}{2} \right) \cdots \left( 1 - \frac{\kappa}{n-1} \right) \\
+ \frac{1}{2} \left( 1 + \kappa \right) \left( 1 + \frac{\kappa}{2} \right) \cdots \left( 1 + \frac{\kappa}{n-1} \right).
\]

(5.22)
It results $b_n(0) = 1$ and $b_n(-\kappa) = b_n(\kappa)$. The first terms of the expansion are

$$\ln_\kappa(1 + x) = x - \frac{x^2}{2} + \left(1 + \frac{\kappa^2}{2}\right) \frac{x^3}{3} - \ldots \quad (5.23)$$

C. The function $\Gamma_\kappa(x)$

The following integral is useful

$$\int_0^1 \left(\ln_\kappa \frac{1}{t}\right)^{r-1} \frac{1}{x} \, dx = \frac{\Gamma\left(\frac{1}{2\kappa} + \frac{r-1}{2}\right)}{\Gamma\left(\frac{1}{2\kappa} + \frac{r-1}{2}\right)} \Gamma(r) \quad (5.24)$$

Starting from the definition of the generalized Euler gamma function, i.e. $\Gamma_\kappa(x)$ given in the previous section, we can write it also in the following alternative but equivalent form

$$\Gamma_\kappa(x) = \left[1 - \kappa^2(x-1)^2\right] \int_0^1 \left(\ln_\kappa \frac{1}{t}\right)^{x-1} \, dt \quad (5.25)$$

An expression of $\Gamma_\kappa(x)$, where the parameter $\kappa$ enters exclusively through the function $\ln_\kappa(.)$, follows easily

$$\Gamma_\kappa(x) = (x-1) \int_0^1 \left(\ln_\kappa \frac{1}{t}\right)^{x-1} \frac{1}{f_t} \, dt \quad (5.26)$$

From the latter relationships follows that $n!_\kappa$ is given by

$$n!_\kappa = (1 - \kappa^2 n^2) \int_0^1 \left(\ln_\kappa \frac{1}{t}\right)^n \, dt = n \int_0^1 \left(\ln_\kappa \frac{1}{t}\right)^n \frac{1}{f_t} \, dt \quad (5.27)$$

D. $\ln_\kappa(x)$ as solution of a functional equation

The logarithm $y(x) = \ln(x)$ is the only existing function, unless a multiplicative constant, which results to be solution of the function equation $y(x_1 x_2) = y(x_1) + y(x_2)$. Let us consider now the generalization of this equation, obtained by substituting the ordinary sum by the generalized sum

$$y(x_1 x_2) = (x_1) \oplus y(x_2) \quad (5.28)$$

We proceed by solving this equation, which assumes the explicit form

$$y(x_1 x_2) = y(x_1) \sqrt{1 + \kappa^2 y(x_2)^2} + y(x_2) \sqrt{1 + \kappa^2 y(x_1)^2} \quad (5.29)$$

After performing the substitution $y(x) = \kappa^{-1}\sinh(\kappa g(x))$ we obtain that the auxiliary function $g(x)$ obeys the equation $g(x_1 x_2) = g(x_1) + g(x_2)$, and then is given by $g(x) = A \ln x$. The unknown function $y(x)$ becomes $y(x) = \kappa^{-1}\sinh(\kappa \ln x)$ where we have set $A = 1$ in order to recover, in the limit $\kappa \to 0$, the classical solution $y(x) = \ln(x)$. Then we can conclude that the solution of Eq. (5.28) is given by

$$y(x) = \ln_\kappa(x) \quad (5.30)$$
E. \( \ln_\kappa(x) \) as solution of a differential-functional equation

The following first order differential-functional equation emerges in statistical mechanics within the context of the maximum entropy principle

\[
\frac{d}{dx} [x f(x)] = \frac{1}{\gamma} f(\epsilon x) ,
\]

\( f(1) = 0 \), \( f'(1) = 1 \), \( f(1/x) = -f(x) \).

The latter problem admits two solutions \[3, 9\]. The first is given by \( f(x) = \ln(x) \) and \( \gamma = 1, \epsilon = e \). The second solution is given by

\[
f(x) = \ln_\kappa(x) ,
\]

and

\[
\gamma = \frac{1}{\sqrt{1 - \kappa^2}} ,
\]

\[
\epsilon = \left(\frac{1 + \kappa}{1 - \kappa}\right)^{1/2\kappa}.
\]

The constant \( \gamma \) is the Lorentz factor corresponding to the reference velocity \( v_* \) while the constant \( \epsilon = \exp_\kappa(\gamma) \), represents the \( \kappa \)-generalization of the Napier number \( e \).

F. The Entropy

A physically meaningful link between the functions \( \ln_\kappa(x) \) and \( \exp_\kappa(x) \) is given by a variational principle. It holds the following theorem:

**Theorem:** Let be \( g(x) \) an arbitrary real function and \( y(x) \) a probability distribution function of the variable \( x \in A \). The solution of the variational equation

\[
\frac{\delta}{\delta y(x)} \left[ -\int_A dx \, y(x) \ln_\kappa y(x) + \int_A dx \, y(x) g(x) \right] = 0 ,
\]

is unique and is given by

\[
y(x) = \frac{1}{\epsilon} \exp_\kappa(\gamma g(x)) ,
\]

being the constants \( \gamma \) and \( \epsilon \) defined by Eqs. (5.36) and (5.37) respectively.

The proof of the theorem is trivial and employs Eqs. (5.31). This theorem permits us to interpret the functional

\[
S_\kappa = -\int_A dx \, y(x) \ln_\kappa y(x) ,
\]

which can be written also in the form

\[
S_\kappa = \int_A dx \, \frac{y(x)^{1-\kappa} - y(x)^{1+\kappa}}{2\kappa} ,
\]

as the entropy associated to the function \( \exp_\kappa(x) \). It is remarkable that in the \( \kappa \to 0 \) limit, as \( \ln_\kappa(y) \) and \( \exp_\kappa(x) \) approach \( \ln(y) \) and \( \exp(x) \) respectively, the new entropy reduces to the old Boltzmann-Shannon entropy.

It is shown that the entropy \( S_\kappa \) has the standard properties of Boltzmann-Shannon entropy: is thermodynamically stable, is Lesche stable, obeys the Khinchin axioms of continuity, maximality, expandability and generalized additivity.
VI. \( \kappa \)-TRIGONOMETRY

A. \( \kappa \)-Hyperbolic Trigonometry

The \( \kappa \)-hyperbolic trigonometry can be introduced by defining the \( \kappa \)-hyperbolic sine and \( \kappa \)-hyperbolic cosine

\[
\sinh_\kappa(x) = \frac{\exp_\kappa(x) - \exp_\kappa(-x)}{2} , \tag{6.1}
\]
\[
\cosh_\kappa(x) = \frac{\exp_\kappa(x) + \exp_\kappa(-x)}{2} , \tag{6.2}
\]

starting from the \( \kappa \)-Euler formula
\[
\exp_\kappa(\pm x) = \cosh_\kappa(x) \pm \sinh_\kappa(x) . \tag{6.3}
\]

In Fig. 5 are plotted the functions \( \sinh_\kappa(x) \) and \( \cosh_\kappa(x) \) for \( \kappa = 0.3 \) (dashed lines). For comparison, in the same figure are reported the corresponding ordinary functions \( \sinh(x) \) and \( \cosh(x) \) (continuous lines).

The \( \kappa \)-hyperbolic tangent and cotangent functions are defined through

\[
\tanh_\kappa(x) = \frac{\sinh_\kappa(x)}{\cosh_\kappa(x)} , \tag{6.4}
\]
\[
\coth_\kappa(x) = \frac{\cosh_\kappa(x)}{\sinh_\kappa(x)} . \tag{6.5}
\]

Holding the relationships

\[
\sinh_\kappa(x) = \sinh(\{x\}) , \tag{6.6}
\]
\[
\cosh_\kappa(x) = \cosh(\{x\}) , \tag{6.7}
\]
\[
\tanh_\kappa(x) = \tanh(\{x\}) , \tag{6.8}
\]
\[
\coth_\kappa(x) = \coth(\{x\}) . \tag{6.9}
\]
it is straightforward to verify that \( \kappa \)-hyperbolic trigonometry preserves the same structure of the ordinary hyperbolic trigonometry which recovers as special case in the limit \( \kappa \to 0 \). For instance from the \( \kappa \)-Euler formula and from \( \exp_\kappa(-x) \exp_\kappa(x) = 1 \) the fundamental formula of the \( \kappa \)-hyperbolic trigonometry follows

\[
\cosh_\kappa^2(x) - \sinh_\kappa^2(x) = 1. \tag{6.10}
\]

All the formulas of the ordinary hyperbolic trigonometry still hold, after proper generalization. Taking into account that \( \{x \oplus y\} = \{x\} + \{y\} \), it is easy to verify that the generalization of a given formula can be obtained starting from the corresponding ordinary formula, and then by making in the arguments of the hyperbolic trigonometric functions the substitutions \( x + y \to x \oplus y \) and \( x - y \to x \ominus y \). For instance it results

\[
\sinh_\kappa(x \oplus y) + \sinh_\kappa(x \ominus y) = 2 \sinh_\kappa(x) \cosh_\kappa(y), \tag{6.11}
\]

\[
\cosh_\kappa(x \oplus y) = \cosh_\kappa(x) \cosh_\kappa(x) + \sinh_\kappa(x) \sinh_\kappa(y), \tag{6.12}
\]

\[
\tanh_\kappa(x) + \tanh_\kappa(y) = \frac{\sinh_\kappa(x \oplus y)}{\cosh_\kappa(x) \cosh_\kappa(y)}, \tag{6.13}
\]

and so on.

Obviously the substitution \( nx \to x \oplus x \oplus \ldots \oplus x = [n] \oplus x \) is required, so that, for instance it holds the formula

\[
\sinh^4_\kappa(x) = \frac{1}{8} \cosh_\kappa([4] \ominus x) - 4 \cosh_\kappa([2] \ominus x) + 3, \tag{6.14}
\]

and so on.

The \( \kappa \)-De Moivre formula involving hyperbolic trigonometric functions having arguments of the type \( rx \), with \( r \in \mathbb{R} \), assumes the form

\[
([\cosh_\kappa(x) \pm \sinh_\kappa(x)]^r = \cosh_{\kappa/r}([r] \ominus x) \pm \sinh_{\kappa/(r)}([r] \ominus x). \tag{6.15}
\]

Also the formulas involving the derivatives of the hyperbolic trigonometric function still hold, after properly generalized. For instance we have

\[
\frac{d}{d_\kappa x} \sinh_\kappa(x) = \cosh_\kappa(x), \tag{6.16}
\]

\[
\frac{d}{d_\kappa x} \tanh_\kappa(x) = \cosh^{-2}_\kappa(x), \tag{6.17}
\]

and so on.

The \( \kappa \)-inverse hyperbolic functions can be introduced starting from the corresponding ordinary functions. It is trivial to verify that \( \kappa \)-inverse hyperbolic functions are related to the \( \kappa \)-logarithm by the usual formulas of the ordinary mathematics. For instance we have

\[
\arcsinh_\kappa(x) = \ln_\kappa \left( \sqrt{1 + x^2} + x \right), \tag{6.18}
\]

\[
\arccosh_\kappa(x) = \ln_\kappa \left( \sqrt{x^2 - 1} + x \right), \tag{6.19}
\]

\[
\arctanh_\kappa(x) = \ln_\kappa \left( \frac{1 + x}{1 - x} \right), \tag{6.20}
\]

\[
\arccoth_\kappa(x) = \ln_\kappa \left( \frac{1 - x}{1 + x} \right), \tag{6.21}
\]

and consequently hold

\[
\arcsinh_\kappa(x) = \arccosh_\kappa \sqrt{1 + x^2} \frac{x}{\sqrt{1 + x^2}}, \tag{6.22}
\]

\[
\arcsinh_\kappa(x) = \arctanh_\kappa \sqrt{1 + x^2} \frac{x}{\sqrt{1 + x^2}}, \tag{6.23}
\]

\[
\arcsinh_\kappa(x) = \arccoth_\kappa \sqrt{1 + x^2} \frac{x}{x}. \tag{6.24}
\]
From Eq. (6.18) follows the relationship
\[ \exp_\kappa (\text{arcsinh}_\kappa x) = \exp (\text{arcsinh} x) \] (6.25)
Also the relationship
\[ \text{arcsinh}_\kappa (x) = \frac{1}{\kappa} \sinh \frac{1}{\kappa} (\kappa x) \] (6.26)
involving the function \text{arcsinh}_\kappa (x), follows from Eq. (6.18). Analogous formulas involving \text{arccosh}_\kappa (x), \text{arctanh}_\kappa (x) or \text{arccoth}_\kappa (x) do not hold instead.

B. \( \kappa \)-Cyclic Trigonometry

By employing the generalized \( \kappa \)-Euler formula
\[ \exp_\kappa (\pm ix) = \cos_\kappa (x) \pm i \sin_\kappa (x) \] (6.27)
we introduce the \( \kappa \)-cyclic sine and \( \kappa \)-cosine as
\[ \sin_\kappa (x) = \frac{\exp_\kappa (ix) - \exp_\kappa (-ix)}{2i} \] (6.28)
\[ \cos_\kappa (x) = \frac{\exp_\kappa (ix) + \exp_\kappa (-ix)}{2} \] (6.29)
while the \( \kappa \)-cyclic tangent and \( \kappa \)-cotangent functions are defined through
\[ \tan_\kappa (x) = \frac{\sin_\kappa (x)}{\cos_\kappa (x)} \] (6.30)
\[ \cot_\kappa (x) = \frac{\cos_\kappa (x)}{\sin_\kappa (x)} \] (6.31)
After noting that
\[ \exp_\kappa (ix) = \exp (i\{x\}) \] (6.32)
with
\[ \{x\} = \frac{1}{\kappa} \arcsin \kappa x \] (6.33)
it follows that the cyclic functions are defined in the interval \(-1/\kappa \leq x \leq 1/\kappa\). The function
\[ [x] = \frac{1}{\kappa} \sin \kappa x \] (6.34)
is defined as the inverse of \( \{x\} \), i.e \([ \{x\}] = \{ [x] \} = x\). The \( \kappa \)-sum \( \oplus \) and \( \kappa \)-product \( \otimes \) given by
\[ x \oplus y = x \sqrt{1 - \kappa^2 y^2} + y \sqrt{1 - \kappa^2 x^2} \] (6.35)
\[ x \otimes y = \frac{1}{\kappa} \sin \left( \frac{1}{\kappa} \arcsin (\kappa x) \arcsin (\kappa y) \right) \] (6.36)
are isomorphic operations to the ordinary sum and product respectively, i.e.
\[ \{x \oplus y\} = \{x\} + \{y\} \] (6.37)
\[ \{x \otimes y\} = \{x\} \cdot \{y\} \] (6.38)
Holding the relationships
\[ \sin_\kappa (x) = \sin (\{x\}) \] (6.39)
\[ \cos_\kappa (x) = \cos (\{x\}) \] (6.40)
\[ \tan_\kappa (x) = \tan (\{x\}) \] (6.41)
\[ \cot_\kappa (x) = \cot (\{x\}) \] (6.42)
it is straightforward to verify that the generalized cyclic trigonometry preserves the same structure of the ordinary cyclic trigonometry, which recovers as special case in the limit $\kappa \to 0$. For instance the following generalized formulas hold

$$\cos_\kappa^2(x) + \sin_\kappa^2(x) = 1, \quad (6.43)$$
$$\sin_\kappa(x + y) = \sin_\kappa(x) \cos_\kappa(y) + \cos_\kappa(x) \sin_\kappa(y), \quad (6.44)$$
$$\cos_\kappa^5(x) = \frac{1}{16} \left[ \cos_\kappa(5 \otimes x) + 5 \cos_\kappa(3 \otimes x) + 10 \cos_\kappa(x) \right], \quad (6.45)$$

and so on.

After introducing the following $\kappa$-deformed derivative operator

$$\frac{d}{d_\kappa x} = \sqrt{1 - \kappa^2 x^2} \frac{d}{d x}, \quad (6.46)$$

we can obtain easily further formulas of the cyclic $\kappa$-trigonometry emerging as generalizations of the corresponding formulas of the ordinary trigonometry. For instance we have

$$\frac{d \cos_\kappa(x)}{d_\kappa x} = -\sin_\kappa(x), \quad (6.47)$$
$$\frac{d \cot_\kappa(x)}{d_\kappa x} = -\sin_\kappa^{-2}(x), \quad (6.48)$$

and so on.

The $\kappa$-inverse cyclic functions can be calculated by inversion of the corresponding direct functions and are given by

$$\arcsin_\kappa(x) = -i \ln_\kappa \left( \sqrt{1 - x^2} + ix \right), \quad (6.49)$$
$$\arccos_\kappa(x) = -i \ln_\kappa \left( \sqrt{x^2 - 1} + x \right), \quad (6.50)$$
$$\arctan_\kappa(x) = i \ln_\kappa \frac{1 + ix}{1 + ix}, \quad (6.51)$$
$$\arccot_\kappa(x) = i \ln_\kappa \frac{ix + 1}{ix - 1}. \quad (6.52)$$

Finally we note that the $\kappa$-cyclic and $\kappa$-hyperbolic trigonometric functions are linked through the relationships

$$\sin_\kappa(x) = -i \sinh_\kappa(ix), \quad (6.53)$$
$$\cos_\kappa(x) = \cosh_\kappa(ix), \quad (6.54)$$
$$\tan_\kappa(x) = -i \tanh_\kappa(ix), \quad (6.55)$$
$$\cot_\kappa(x) = i \coth_\kappa(ix), \quad (6.56)$$
$$\arcsin_\kappa(x) = -i \arcsinh_\kappa(ix), \quad (6.57)$$
$$\arccos_\kappa(x) = -i \arccosh_\kappa(x), \quad (6.58)$$
$$\arctan_\kappa(x) = -i \arctanh_\kappa(ix), \quad (6.59)$$
$$\arccot_\kappa(x) = i \arccoth_\kappa(ix), \quad (6.60)$$

which in the $\kappa \to 0$ limit reduce to the standard formulas involving the ordinary cyclic and hyperbolic functions.
