VOLTAGE LIFTS OF GRAPHS FROM A CATEGORY THEORY VIEWPOINT

GEJZA JENČA

ABSTRACT. We prove that the notion of a voltage graph lift comes from an adjunction between the category of voltage graphs and the category of group labeled graphs.

1. INTRODUCTION

In this paper, a graph means a structure sometimes called a symmetric multidigraph – that means that it may have multiple darts with the same source and target, and the set of all darts of the graph is equipped with an involutive mapping \( \lambda \) that maps every dart to a dart with source and target swapped.

A voltage graph is a graph in which every dart is labeled with an element of a group in a way that respects the involutive symmetry \( \lambda \), so that the label of a dart \( d \) is inverse to the label of \( \lambda(d) \). Similarly, a group labeled graph has all vertices labeled with elements of a group.

In [8] Gross introduced the construction of a derived graph of a voltage graph. Nowadays, derived voltage graphs are called (ordinary) voltage graph lifts – this is the terminology we will use in the present paper. Let us mention in passing that in [9], voltage graphs were generalized to a more general notion of permutation voltage graphs, in which the darts are labelled with permutations.

After their discovery, voltage graph lifts were extensively investigated in many papers. Voltage graph lifts were applied for example in the research concerning the degree-diameter problem [3, 4], lifting graph automorphisms [15] and several other areas of graph theory.

In the present paper, we prove that there is an adjunction

\[
\begin{array}{ccc}
\text{Lab} & \xrightarrow{L} & \text{Volt} \\
\downarrow & & \downarrow \\
\text{Lab} & \xleftarrow{R} & \text{Volt}
\end{array}
\]

between the category \textbf{Volt} of voltage graphs and a category \textbf{Lab} of group labeled graphs. We prove that for every object \( G \) of \textbf{Volt}, the underlying graph of the voltage graph \( LR(G) \) is isomorphic to the voltage graph lift of \( G \).

Key words and phrases. voltage graphs, derived graph, voltage graph lift, adjoint functors.

This research is supported by grants VEGA 2/0142/20 and 1/0006/19, Slovakia and by the Slovak Research and Development Agency under the contracts APVV-18-0852 and APVV-20-0069.
2. Preliminaries

We assume basic knowledge of category theory; for notions not explained here see [14, 16].

2.1. Adjunctions. There are several different but equivalent definitions of an adjoint pair of functors. For our purposes, the following is the most convenient one.

Definition 2.1. [14, (ii) of Theorem IV.1] Let $C, D$ be categories and let $F: C \rightarrow D$ and $G: D \rightarrow C$ be functors. We say that $F$ is left adjoint to $G$, or that $G$ is right adjoint to $F$, in symbols $F \dashv G$, if there is a family

$$\{\epsilon_Y : FG(Y) \rightarrow Y\}_{Y \in \text{obj}(D)}$$

of $D$-morphisms, such that for every $C$-object $X$ and a $D$-morphism $f: F(X) \rightarrow Y$ there is a unique $C$-morphism $u: X \rightarrow G(Y)$ such that

$$\begin{array}{ccc}
F(X) & \xrightarrow{f} & Y \\
F(u) \downarrow & \searrow \epsilon_Y & \\
FG(Y) \downarrow & & Y
\end{array}$$

commutes.

The family $\{\epsilon_Y\}_{Y \in \text{obj}(D)}$ then forms a natural transformation of functors $\epsilon: FG \rightarrow \text{id}_D$, called the counit of the adjunction $F \dashv G$.

An important fact concerning the notion of an adjoint pair of functors is that each of the functors $F, G$ determines the other one and the counit, up to isomorphism.

We will need another (perhaps more familiar) characterization of an adjoint pair of functors. For objects $O_1, O_2$ of a category $\mathcal{E}$, write $\mathcal{E}(O_1, O_2)$ for the set of all morphisms from $O_1$ to $O_2$ in $\mathcal{E}$.

Let $\mathcal{C}, \mathcal{D}$ be categories, let $F: \mathcal{C} \rightarrow \mathcal{D}$ and $G: \mathcal{D} \rightarrow \mathcal{C}$ be functors. Then $F \dashv G$ if and only if there is a bijection, natural in $X$ and $Y$,

$$\mathcal{C}(F(X), Y) \simeq \mathcal{D}(X, G(Y)).$$

See [14, section IV.1].

2.2. Pullbacks. Let $f: X \rightarrow A, q: B \rightarrow A$ be a pair of morphisms in a category $\mathcal{C}$ with a common codomain $A$, sometimes called a cospan in $\mathcal{C}$

\[(1)\]

$$\begin{array}{ccc}
X & \xrightarrow{f} & A \\
\downarrow & & \\
B & \xrightarrow{q} & A
\end{array}$$

Then a pullback is the limit of this diagram. In other words, it is an object (denoted by $X \times_A B$) equipped with morphisms $q^*(f): X \times_A B \rightarrow B$ and $f^*(q): X \times_A B \rightarrow X$.
such that the square (2.3) in the diagram

\[
\begin{array}{c}
V \\
\downarrow u \\
\downarrow v_X \\
\downarrow v_B \\
\downarrow f \\
B \\
\downarrow q \\
A
\end{array}
\]

commutes and for every object \( V \) and a pair of morphisms \( v_X: V \to X \) and \( v_B: V \to B \) such that the outer square of the diagram (2) commutes, there is a unique morphism \( u: V \to X \times_A B \) such that both triangles (2.1) and (2.2) commute. We say that \( q^*(f) \) is a pullback of \( f \) along \( q \) and that \( f^*(q) \) is a pullback of \( q \) along \( f \).

Let us describe pullbacks in the usual category of sets and mappings, denoted by \( \text{Set} \).

**Example 2.2.** Consider a diagram of shape (1) in \( \text{Set} \). A pullback \( X \times_A B \) can be constructed as a subset of the direct product of sets \( X \times B \), given by

\[
X \times_A B = \{ (x, b) : f(x) = q(b) \}
\]

and the maps \( f^*(q) \) and \( q^*(f) \) are the projections:

\[
f^*(q)(x, b) = x \quad q^*(f)(x, b) = b.
\]

Note that, whenever \( A \) is a singleton, \( f(x) = q(b) \) for all pairs \( (x, b) \in X \times B \), so in this case \( X \times_A B = X \times B \).

### 2.3. Graphs

A graph is a quintuple \( G = (V, D, s, t, \lambda) \), where

- \( D \) is the set of darts of \( G \)
- \( V \) is the set of vertices of \( G \)
- \( s, t: D \to V \) are the source and target maps, respectively.
- \( \lambda: D \to D \) is a mapping such that \( \lambda \circ \lambda = \text{id}_D \).
- \( s \circ \lambda = t \).

The mapping \( \lambda \) is called the dart-reversing involution of \( G \). Note that \( t \circ \lambda = s \circ \lambda \circ \lambda = s \circ \text{id}_D = s \).

All the data in a graph \( (V, D, s, t, \lambda) \) can be expressed graphically by a commutative diagram:

\[
\begin{array}{c}
D \\
\downarrow \text{id}_D \\
D
\end{array}
\]

We write \( V(G) \) for the set of vertices of \( G \) and \( D(G) \) for the set of darts of \( G \). Usually we will identify \( G \) with the pair \( (V(G), D(G)) \) and discard \( s, t, \lambda \) from the signature. We say that \( s, t, \lambda \) are the structure maps of \( G \).

Note that \( \lambda \) comes from an action of \( \mathbb{Z}_2 \) on \( D \). The orbits of \( \lambda \) are the edges of \( G \). We write \( E(G) \) for the set of all edges. There are three types of edges \{\( d, \lambda(d) \}\):
**semiedges:** $\lambda(d) = d$;

**loops:** non-semiedges with $s(d) = t(d)$;

**links:** all the other edges, that means $\lambda(d) \neq d$ and $s(d) \neq t(d)$.

A morphism of graphs $f : G \to H$ is a pair of mappings $(f^V, f^D)$, where $f^V : V(G) \to V(H)$ and $f^D : D(G) \to D(H)$ are such that for every dart $d \in D(G)$, $s(f^D(d)) = f^V(s(d))$, $t(f^D(d)) = f^V(t(d))$ and $\lambda(f^D(d)) = f^D(\lambda(d))$. Clearly, graphs equipped with morphisms form a category, denoted by Graph.

### 2.4. Graphs are functors.

As outlined above, every graph is a diagram in Set. This can be formulated as follows: a graph is a functor from a certain finite category $\mathbf{gph}$ to the category Set. This category $\mathbf{gph}$ has two objects $\{D, V\}$, and three non-identity morphisms $\{s, t, \lambda\}$ that behave as in the diagram (3). The morphisms of graphs can then be represented as natural transformations of functors from $\mathbf{gph}$ to Set, so the category Graph can be identified with a category of functors $[\mathbf{gph}, \mathbf{Set}]$.

### 2.5. Pullbacks of graphs.

Since graphs are functors, it follows that limits/colimits in Graph can be computed pointwise: we can compute a limit/colimit separately for vertices and darts and then equip the resulting sets with structure maps to obtain a graph.

In particular, given a pair of morphisms $f_1, f_2$

\[ \begin{array}{c} G_1 \\ \downarrow f_1 \\ G_2 \rightarrow^f \rightarrow^g H \end{array} \]

in Graph, we can compute the pullback simply as

\[
\begin{align*}
V(G_1 \times_H G_2) &= V(G_1) \times_{V(H)} V(G_2) \\
D(G_1 \times_H G_2) &= D(G_1) \times_{D(H)} D(G_2) \\
s(d_1, d_2) &= (s(d_1), s(d_2)) \\
t(d_1, d_2) &= (t(d_1), t(d_2)) \\
\lambda(d_1, d_2) &= (\lambda(d_1), \lambda(d_2)).
\end{align*}
\]

The projections $f_1^*(f_2), f_2^*(f_1)$ in

\[ \begin{array}{c} G_1 \times_H G_2 \rightarrow^{f_2^*(f_1)} \rightarrow^{f_1^*(f_2)} G_1 \\ \downarrow f_1 \downarrow f_2 \\ G_2 \rightarrow^f \rightarrow^g H \end{array} \]

are computed in the obvious way:

\[
\begin{align*}
(f_2^*(f_1))^V(v_1, v_2) &= v_1 \\
(f_1^*(f_2))^V(v_1, v_2) &= v_2 \\
(f_2^*(f_1))^D(d_1, d_2) &= d_1 \\
(f_1^*(f_2))^D(d_1, d_2) &= d_2.
\end{align*}
\]
2.6. **Group labeled graphs.** A **group labeled graph** is a triple $(G, \Gamma, \beta)$, where $G$ is a graph, $\Gamma$ is a group and $\beta : V(G) \to \Gamma$ is a mapping, called a $\Gamma$-labeling on $G$.

A morphism of group labeled graphs $(G, \Gamma, \beta) \to (G', \Gamma', \beta')$ is a pair $(f, h)$, where $f : G \to G'$ is a morphism of graphs and $h : \Gamma \to \Gamma'$ is a morphism of groups such that, for all $v \in V(G)$, $h(\beta(v)) = \beta'(f^V(v))$. The composition of morphisms is defined in a straightforward way: $(f_1, h_1) \circ (f_2, h_2) = (f_1 \circ f_2, h_1 \circ h_2)$. Clearly, the class of all group labeled graphs equipped with their morphisms forms a category, which we denote by $\text{Lab}$.

Let $X$ be a set. Let $\hat{k}(X)$ be the complete graph with semiedges on the vertex set $X$, that means, a graph with $V(\hat{k}(X)) = X$, $D(\hat{k}(X)) = X \times X$, and structure maps $s(x_1, x_2) = x_1$, $t(x_1, x_2) = x_2$ and $\lambda(x_1, x_2) = (x_2, x_1)$. Clearly, $\hat{k}$ is a functor from $\text{Set}$ to $\text{Graph}$.

Let us write $U : \text{Grp} \to \text{Set}$ for the “forgetful” functor that maps a group to its underlying set and denote $\hat{K} = \hat{k} \circ U$, so that $\hat{K}(\Gamma)$ is the complete graph with semiedges with vertices labelled by the elements of the group $\Gamma$.

**Proposition 2.3.** The functor $\hat{K}$ is a right adjoint.

**Proof.** Obviously, for every set $X$ and a graph $G$,

$$\text{Set}(V(G), X) \simeq \text{Graph}(\hat{k}(X), \hat{k}(X)),$$

hence $V \dashv \hat{k}$. It is well known that $U$ is a right adjoint functor with $F \dashv U$, where the left adjoint $F : \text{Set} \to \text{Grp}$ maps every set $X$ to the free group generated by $X$. Right adjoint functors are closed with respect to composition, hence $\hat{K} = \hat{k} \circ U$ is a right adjoint. \hfill $\square$

**Corollary 2.4.** For every pair $\Gamma_1, \Gamma_2$ of groups, $\hat{K}(\Gamma_1 \times \Gamma_2) \simeq \hat{K}(\Gamma_1) \times \hat{K}(\Gamma_2)$.

**Proof.** Every right adjoint functor preserves limits. \hfill $\square$

A $\Gamma$-labeling $\beta$ on a graph $G$ is the same thing as a morphism of graphs $G \to \hat{K}(\Gamma)$. Moreover, a morphism $(f, h) : (G, \Gamma, \beta) \to (G', \Gamma', \beta')$ in $\text{Lab}$ can be identified with a commutative square in $\text{Graph}$

$$
\begin{array}{ccc}
G & \xrightarrow{f} & G' \\
\beta \downarrow & & \downarrow \beta' \\
\hat{K}(\Gamma) & \xrightarrow{\hat{k}(h)} & \hat{K}(\Gamma')
\end{array}
$$

Composition of morphisms in $\text{Lab}$ corresponds to horizontal pasting of such commutative squares. This shows that the category $\text{Lab}$ is isomorphic to the comma category $\text{Graph} \downarrow \hat{K}$, see [14, Section II.6].

2.7. **Voltage graphs.** A **voltage graph** is a triple $(G, \Gamma, \alpha)$, where $G$ is a graph and $\alpha : D(V) \to \Gamma$ is a mapping such that $\alpha(\lambda(d)) = (\alpha(d))^{-1}$, called a $\Gamma$-**voltage on** $G$.

A morphism of voltage graphs $(G, \Gamma, \alpha) \to (G', \Gamma', \alpha')$ is a pair $(f, h)$, where $f : G \to G'$ is a morphism of graphs and $h : \Gamma \to \Gamma'$ is a morphism of groups such that, for all $d \in D(G)$, $h(\alpha(d)) = \alpha'(f^D(d))$. The composition is defined similarly as in $\text{Lab}$. The class of all voltage graphs equipped with morphisms of voltage graphs forms a category, which we denote by $\text{Volt}$. 
Similarly as for \textbf{Lab}, it is possible to represent \textbf{Volt} as a certain category of morphisms in \textbf{Graph}. Indeed, consider the digraph \( \ell(\Gamma) \) with a single vertex \( v \) and \( D(\ell(\Gamma)) = \Gamma \). Both \( s \) and \( t \) are just constant maps with the constant \( v \) and \( \lambda: D(\ell(\Gamma)) \to D(\ell(\Gamma)) \) is given by \( \lambda(a) = a^{-1} \); \( \ell \) is then a functor from \textbf{Grp} to \textbf{Graph}. Note that the edge \( \{a, \lambda(a)\} \) of \( \ell(\Gamma) \) is a semiedge for \( a = a^{-1} \), otherwise it is a loop.

**Proposition 2.5.** \( \ell \) is a right adjoint functor.

**Proof.** The proof is very similar to the proof of Proposition 2.3 however one needs to replace the intermediate category \textbf{Set} with the category \textbf{Act}(\( \mathbb{Z}_2 \)) of actions of \( \mathbb{Z}_2 \) equipped with equivariant maps. The functor \( F_\ell: \textbf{Graph} \to \textbf{Grp} \) takes a graph to the group with the set of generators \( D(G) \) and the set of relations given by \( d.\lambda(d) = 1 \), for all \( d \in D(G) \) and it is easy to check that \( F_\ell \vdash \ell \).

**Corollary 2.6.** For every pair \( \Gamma_1, \Gamma_2 \) of groups, \( \ell(\Gamma_1 \times \Gamma_2) \cong \ell(\Gamma_1) \times \ell(\Gamma_2) \).

**Proof.** Every right adjoint functor preserves limits.

A voltage \( \alpha \) on a graph \( G \) is the same thing as a morphism of graphs \( \alpha: G \to \ell(\Gamma) \). Under this identification, a morphism in \textbf{Volt} \((f, h): (G, \Gamma, \alpha) \to (G', \Gamma', \alpha')\) is the same thing as a commutative square in \textbf{Graph}

\[
\begin{array}{ccc}
G & \xrightarrow{f} & G' \\
\downarrow{\alpha} & & \downarrow{\alpha'} \\
\ell(\Gamma) & \xrightarrow{\ell(h)} & \ell(\Gamma')
\end{array}
\]

and composition of morphisms corresponds to horizontal pasting of such squares. This shows that the category \textbf{Volt} is isomorphic to the comma category \textbf{Graph} \( \downarrow \ell \).

### 2.8. Derived voltage graphs.

**Definition 2.7.** [10] Let \((G, \Gamma, \alpha)\) be a voltage graph. There is a voltage graph lift of \((G, \Gamma, \alpha)\), denoted by \((G^\alpha, \Gamma, \alpha')\)

- \(V(G^\alpha) = V(G) \times \Gamma\)
- \(D(G^\alpha) = D(G) \times \Gamma\)
- \(s(d, x) = (s(d), x)\)
- \(t(d, x) = (t(d), x.\alpha(d))\)
- \(\lambda(d, x) = (\lambda(d), x.\alpha(d))\)
- \(\alpha'(d, x) = \alpha(d)\)

Let us remark that in the original definition in [8], the voltage graph lift of a voltage graph is just a graph (not a voltage graph).

For every voltage graph \((G, \Gamma, \alpha)\), there is a morphism \( \epsilon_{(G, \Gamma, \alpha)} \) of graphs from \( G^\alpha \) to \( G \) given by the projection \( \epsilon^V_{(G, \Gamma, \alpha)}(v, x) = v, \epsilon^D_{(G, \Gamma, \alpha)}(d, x) = d \). Clearly, this is a morphism in \textbf{Volt}. We will prove in the next section that this morphism is a component of the counit of an adjunction between \textbf{Volt} and \textbf{Lab}.

**Example 2.8.** Consider the \( \mathbb{Z}_3 \)-voltage graph at the bottom of Figure 1; for every edge we draw only one of its two darts. The voltage graph lift is pictured at the top of the figure.
2.9. **Fibrations and covers.** An *in-neighbourhood* $N(v)$ of a vertex $v$ of a graph is the set of darts with target $v$. A morphism of graphs $f : G' \to G$ is a *fibration* if for every vertex $v \in V(G')$, $f^E$ restricted to $N(v)$ is a bijection from $N(v)$ to $N(f(v))$. A fibration is a *covering* if and only if it is surjective on vertices. The following proposition is well-known.

**Proposition 2.9.** For every voltage graph $(G, \Gamma, \alpha)$, the canonical projection $p : G^\alpha \to G$ given by $p^V(v, x) = v$ and $p^D(d, x) = d$ is a covering.

A covering $f : G' \to G$ is *regular* if there is a group $\Gamma$ that acts freely on $G'$ and an isomorphism $i : G'/\Gamma \to G$ such that $i \circ \omega \Gamma = f$, where $\omega \Gamma : G' \to G'/\Gamma$ is the quotient map of the action.

For every voltage graph $(G, \Gamma, \alpha)$, $\Gamma$ acts freely on $G^\alpha$ and the canonical projection $p : G^\alpha \to G$ is a regular covering associated with this action. Moreover, it can be proved that every regular covering $f : G' \to G$ is isomorphic to the canonical projection for some voltage on $G$ (see [8] or [10], Theorems 2.2.1 and 2.2.2).

The more general notion of permutation voltage graphs can be used to represent all coverings of graphs [9].

### 3. The adjunction between **Volt** and **Lab**

Consider a group labeled graph $(G, \Gamma, \beta)$. If we want to construct a voltage graph from $(G, \Gamma, \beta)$, it is natural to equip darts of $G$ with a voltage given by the “quotient” of labels along the edge. Formally, there is a voltage graph $L(G, \Gamma, \beta) = (G, \Gamma, \alpha)$, with the voltage $\alpha$ given by the rule $\alpha(d) = \beta(s(d))^{-1} \beta(t(d))$, see Figure 2. For an abelian group $\Gamma$, this construction of a voltage graph from a $\Gamma$-labeled graph is well-known in the theory of flows on graphs [2] Chapter II; in this context, the vertex labels are called potentials. It is clear that every $L(G, \Gamma, \beta)$ satisfies the Kirchhoff laws. Moreover, it is easy to check that every voltage graph $(G, \Gamma, \alpha)$ that satisfies the Kirchhoff laws is in the range of the functor $L$. 

---

**Figure 1.** A $\mathbb{Z}_3$-voltage graph and its voltage graph lift
For every group $\Gamma$, there is a morphism of graphs $q_\Gamma : \hat{K}(\Gamma) \to \ell(\Gamma)$; $q_\Gamma^V$ is the only possible map and $q_\Gamma^D(u,v) = u^{-1}v$.

If we identify $\text{Lab} \simeq \text{Graph} \downarrow \hat{K}$ and $\text{Volt} \simeq \text{Graph} \downarrow \ell$, then $L(G,\Gamma,\beta)$ is the voltage graph $(G,\Gamma,q_\Gamma \circ \beta)$.

So in what follows, we sometimes write $L(\beta)$ for $q_\Gamma \circ \beta$.

**Proposition 3.1.** The family of morphisms $\{q_\Gamma\}_{\Gamma \in \text{obj}(\text{Grp})}$ is a natural transformation from $\hat{K}$ to $\ell$.

**Proof.** Let $h : \Gamma \to \Gamma'$ be a morphism of groups. We need to prove that the naturality square at $h$

\[
\begin{array}{ccc}
\hat{K}(\Gamma) & \xrightarrow{\hat{K}(h)} & \hat{K}(\Gamma') \\
\downarrow q_\Gamma & & \downarrow q_{\Gamma'} \\
\ell(\Gamma) & \xrightarrow{\ell(h)} & \ell(\Gamma')
\end{array}
\]

commutes. For vertex components of the morphisms, this is trivial because $\ell(\Gamma')$ has only one vertex. For every $d \in D(\hat{K}(\Gamma))$, that means, $d = (u,v) \in \Gamma \times \Gamma$ we can compute

\begin{align*}
(\ell(h))^D(q_\Gamma^D(u,v)) &= (\ell(h))^D(u^{-1}v) = h(u^{-1}v) = (h(u))^{-1}h(v) \\
q_{\Gamma'}^D(\hat{K}(h)^D(u,v)) &= q_{\Gamma'}^D(h(u),h(v)) = (h(u))^{-1}h(v)
\end{align*}

$\square$

Let $(f,h) : (G,\Gamma,\beta) \to (G',\Gamma',\beta')$ be a morphism in $\text{Lab}$. Consider the diagram
Since \((f, h)\) is a morphism in \(\text{Lab}\), the square (4.1) commutes. By Proposition 3.1, the square (4.2) commutes. The left and right vertical composites \(q \circ \beta\) and \(q \circ \beta'\) are \(L(\beta)\) and \(L(\beta')\), respectively. So the whole diagram (4) commutes and we see that \((f, h)\) is a morphism from \(L(\beta)\) to \(L(\beta')\) in \(\text{Volt}\). Thus, we may put \(L(f, h) = (f, h)\), and it is then clear that \(L\) is a functor.

**Theorem 3.2.** \(L\) is a left adjoint functor.

**Proof.** Let us describe a right adjoint functor \(R: \text{Volt} \to \text{Lab}\) associated to the functor \(L\). For every voltage graph \((G, \Gamma, \alpha)\), we put \(R(G, \Gamma, \alpha) = (G \times \ell(\Gamma), \Gamma, q^*_{\ell}(\alpha))\):

\[
\begin{array}{ccc}
G \times \ell(\Gamma) & \xrightarrow{\alpha^*(q_{\ell})} & G \\
q^*_{\ell}(\alpha) \downarrow & & \downarrow \alpha \\
\hat{K}(\Gamma) & \xrightarrow{\hat{K}(h)} & \hat{K}(\Gamma')
\end{array}
\]

To specify \(R\) on morphisms we use the fact that pullback is a limit. In detail, let

\((f, h): (G, \Gamma, \alpha) \to (G', \Gamma', \alpha')\)

be a morphism of voltage graphs. Consider the diagram in \(\text{Graph}\):

\[
\begin{array}{ccc}
G \times \ell(\Gamma) & \xrightarrow{\alpha^*(q_{\ell})} & G' \times \ell(\Gamma') \\
\downarrow \alpha \downarrow \downarrow \alpha' \downarrow \\
\hat{K}(\Gamma) & \xrightarrow{\hat{K}(h)} & \hat{K}(\Gamma')
\end{array}
\]

The cell (6.1) is a pullback square, the cell (6.5) is a naturality square for \(q\) at \(h\), and the middle cell (6.3) is just the \((f, h)\) morphism in \(\text{Volt}\). Therefore, the boundary of the diagram consisting of (6.1), (6.5) and (6.3) commutes, meaning that

\[\alpha' \circ f \circ \alpha^*(q_{\ell}) = q_{\ell'} \circ \hat{K}(h) \circ (q^*_{\ell}(\alpha)).\]

Since (6.4) is a pullback square over the span \((\alpha', q_{\ell'})\), there is a unique morphism \(u\) such that both (6.2) and the outer square of (4) commute. Since the outer square

\[
\begin{array}{ccc}
G & \xrightarrow{f} & G' \\
\beta \downarrow & & \beta' \downarrow \\
\hat{K}(\Gamma) & \xrightarrow{\hat{K}(h)} & \hat{K}(\Gamma')
\end{array}
\]

(4)
of (6) commutes, \((u, h)\) is a morphism from \(R(\alpha)\) to \(R(\alpha')\) in \(\text{Lab}\), and we may put \(R(f, h) = (u, h)\). We omit the proof of functoriality of \(R\) since it is just a straightforward exercise in the “universality of the pullback”.

However, it is also possible to observe that \(R\) is a functor by describing \(u\) explicitly:

\[
u^V(v, x) = (f^V(v), h(x)) \quad u^D(d, (x_1, x_2)) = (f^D(d), (h(x_1), h(x_2))).\]

To specify the counit, we first note that for a voltage graph \((G, \Gamma, \alpha)\), \(LR(G, \Gamma, \alpha)\) is the voltage graph \((G \times_{\ell(\Gamma)} \tilde{K}(\Gamma), \Gamma, q_{\Gamma} \circ q_T^l(\alpha))\). For every object \((G, \Gamma, \alpha)\) of \(\text{Volt}\), we define \(\epsilon(G, \Gamma, \alpha) : LR(G, \Gamma, \alpha) \to (G, \Gamma, \alpha)\) to be the morphism \((\alpha^* q_T, \text{id}_\Gamma)\) in \(\text{Volt}\):

\[
\begin{array}{cccc}
G \times_{\ell(\Gamma)} \tilde{K}(\Gamma) & \overset{\alpha^* (q_T)}{\longrightarrow} & G \\
q_T^l(\alpha) \downarrow & & \alpha \downarrow \\
\tilde{K}(\Gamma) \downarrow & & \tilde{K}(\Gamma) \downarrow \\
q_T \downarrow & & \ell(\Gamma) \downarrow & \ell(\Gamma) \\
\ell(\Gamma) & \overset{\ell(\text{id}_\Gamma)}{\longrightarrow} & \ell(\Gamma)
\end{array}
\]

Note that the commutativity of (7) follows from the commutativity of (6).

To prove that the family of all these \(\epsilon(G, \Gamma, \alpha)\) is a counit of the adjunction \(L \dashv R\), we need to prove that for every group labelled graph \((G', \Gamma', \beta)\) and every morphism of voltage graphs \((f, h) : L(G', \Gamma', \beta) \to (G, \Gamma, \alpha)\)

there is a unique morphism of group labelled graphs \((u, w) : (G', \Gamma', \beta) \to R(G, \Gamma, \alpha)\) such that the diagram in \(\text{Volt}\):

\[
\begin{array}{cccc}
L(G', \Gamma', \beta) & \overset{(f, h)}{\longrightarrow} & (G, \Gamma, \alpha) \\
L(u, w) \downarrow & & \downarrow \epsilon(G, \Gamma, \alpha) \\
LR(G, \Gamma, \alpha) & \overset{(f, h)}{\longrightarrow} & (G, \Gamma, \alpha)
\end{array}
\]

commutes. If such \((u, w)\) exists, then \(\epsilon(G, \Gamma, \alpha) \circ L(u, w) = (f, h)\) in \(\text{Volt}\) implies that \(\text{id}_\Gamma \circ w = h\) in \(\text{Grp}\), so \(w = h\), and the uniqueness of \(w\) is thus clear. What remains to prove is the existence and uniqueness of \(u\), under the assumption \(w = h\).

The assumption that \((f, h)\) in (8) is a morphism of voltage graphs means that the diagram

\[
\begin{array}{cccc}
G' & \overset{f}{\longrightarrow} & G \\
\beta \downarrow & & \downarrow \alpha \\
\tilde{K}(\Gamma') & \overset{\alpha}{\longrightarrow} & \tilde{K}(\Gamma) \\
q_{\Gamma'} \downarrow & & \downarrow q_T^l(\alpha) \\
\ell(\Gamma') & \overset{\ell(\text{id}_\Gamma)}{\longrightarrow} & \ell(\Gamma)
\end{array}
\]
in **Graph** commutes. Consider the diagram

(10)

The outer border of (10) is the commutative square (9) – the \((f, h)\) morphism we want to express as in (8). In particular, we already know that the outer border of (10) commutes. The square (10.4) commutes because it is the naturality square for \(q\) at \(h\). From this, we obtain

\[
q_{\Gamma'} \circ K(h) \circ \beta = \alpha \circ f
\]

and by the universality of the pullback \(G \times_{l(\Gamma)} \hat{K}(\Gamma)\) there is a unique \(u: G' \to G \times_{l(\Gamma)} \hat{K}(\Gamma)\) such that

\[
q_{\Gamma}(\alpha) \circ u = K(h) \circ \beta \quad (10.1)
\]

\[
\alpha^*(q_{\Gamma'}) \circ u = f \quad (10.2)
\]

Note that the commutative square (10.1) is just a **Lab**-morphism \((u, h): (G', \Gamma', \beta) \to R(G, \Gamma, \alpha)\). Applying the functor \(L\) on \((u, h)\), that means, pasting of the squares (10.1) and (10.4) gives us a morphism \(L(u, h): L(G', \Gamma', \beta) \to LR(G, \Gamma, \alpha)\). The cell (10.3) is just \(\epsilon_{(G, \Gamma, \alpha)}\). Composing in **Volt** \(\epsilon_{(G, \Gamma, \alpha)} \circ L(u, h)\) gives us the **Volt**-morphism

\[
(\alpha^*(q_{\Gamma'}) \circ u, h): L(G'(\Gamma, \Gamma', \beta) \to \alpha
\]

and we already know that \(\alpha^*(q_{\Gamma'}) \circ u = f\), so \(\epsilon_{(G, \Gamma, \alpha)} \circ L(u, h) = (f, h)\). It remains to note that we have already proved the uniqueness of \(u\).

Let us examine the structure of \(R(G, \Gamma, \alpha)\) for the case of a single-vertex graph \(G\). By our main result Theorem 3.5 and [10, Theorem 2.2.3], we see that \(R(G, \Gamma, \alpha)\) is a Cayley graph. However, it is perhaps interesting to describe the behaviour of our construction in this case.

**Definition 3.3.** Let \(\Gamma\) be a group and let \(S\) be a subset of \(\Gamma\) that is closed under taking inverses. The **Cayley graph of \(\Gamma\) induced by \(S\)** is the graph \(\mathcal{C}(\Gamma, S)\) with vertices \(V(\mathcal{C}(\Gamma, S)) = \Gamma\) and darts

\[
D(\mathcal{C}(\Gamma, S)) = \{(x, y) \in \Gamma \times \Gamma: x^{-1}y \in S\}.
\]

The structural maps of \(\mathcal{C}(\Gamma, S)\) are

\[
s(x, y) = x
\]

\[
t(x, y) = y
\]

\[
\lambda(x, y) = (y, x)
\]
Naturally, every $C(\Gamma, S)$ is a $\Gamma$-labeled graph, with the labeling given by $\beta(x) = x$.

**Corollary 3.4.** Let $\Gamma$ be a group and let $S$ be a subset of $\Gamma$ that is closed with respect to taking inverses. Let $(G, \Gamma, \alpha)$ be a voltage graph with a single vertex $v$, such that $D(G) = S$ and $\alpha(x) = x$. As a group-labeled graph, $R(G, \Gamma, \alpha)$ is isomorphic to the Cayley graph of $\Gamma$ induced by $S$.

**Proof.** Let us compute $R(G, \Gamma, \alpha)$ as a pullback (5). Clearly, since $V(\ell(\Gamma))$ is a singleton,

$$V(G \times \ell(\Gamma) \tilde{K}(\Gamma)) = V(G) \times V(\tilde{K}(\Gamma)) = \{v\} \times \Gamma$$

For darts, we can compute a pullback in $\textbf{Set}$

$$D(G \times \ell(\Gamma) \tilde{K}(\Gamma)) = D(G) \times D(\ell(\Gamma)) \times D(\tilde{K}(\Gamma)) = S \times (\Gamma \times \Gamma).$$

The pullback square in $\textbf{Set}$ is

\[
\begin{array}{ccc}
S \times (\Gamma \times \Gamma) & \xrightarrow{j^*(m)} & S \\
\downarrow{m^*(j)} & & \downarrow{j} \\
\Gamma \times \Gamma & \xrightarrow{q^*_\Gamma} & \Gamma
\end{array}
\]

where $j$ is the inclusion of $S$ into $\Gamma$. We have

$$S \times (\Gamma \times \Gamma) = \{(u, (x, y)) : u \in S \text{ and } x^{-1}y = u\}$$

The structure maps of the pullback graph are

$$s(u, (x, y)) = (s(u), s(x, y)) = (v, x)$$
$$t(u, (x, y)) = (t(u), t(x, y)) = (v, y)$$
$$\lambda(u, (x, y)) = (\lambda(u), \lambda(x, y)) = (u^{-1}, (y, x))$$

and its labeling is given by $\beta(v, x) = x$. Moreover, note that there are obvious isomorphisms of sets $\{v\} \times \Gamma \simeq \Gamma$ and

$$\{(u, (x, y)) : u \in S \text{ and } x^{-1}y = u\} \simeq \{(x, y) : x^{-1}y \in S\}$$

and it is easy to see that this pair of isomorphisms of sets give us an isomorphism $R(G, \Gamma, \alpha) \simeq C(\Gamma, S)$ in $\textbf{Lab}$. \hfill $\square$

**Theorem 3.5.** For every voltage graph $(G, \Gamma, \alpha)$, the graph $LR(G, \Gamma, \alpha)$ is isomorphic to the voltage graph lift of $(G, \Gamma, \alpha)$.

**Proof.** We adopt the notations of Definition 2.7 here. The underlying graph of $LR(G, \Gamma, \alpha)$ is $G \times \ell(\Gamma) \tilde{K}(\Gamma)$. Let us examine its structure and prove that there is an isomorphism $j : LR(G) \rightarrow G^\alpha$.

As $V(\ell(\Gamma))$ is a singleton,

$$V(G \times \ell(\Gamma) \tilde{K}(\Gamma)) = V(G) \times V(\tilde{K}(\Gamma)) = V(G) \times \Gamma,$$

so $V(LR(G, \Gamma, \alpha)) = V(G^\alpha)$ and we may put $j^V(v, x) = (v, x)$.

For darts, we see that

$$D(G \times \ell(\Gamma) \tilde{K}(\Gamma)) = \{((d, (x_1, x_2)) \in D(G) \times D(\tilde{K}(\Gamma)) : q^*_d(x_1, x_2) = \alpha(d)\}.$$
The structure maps of $G \times_{\ell(\Gamma)} \hat{K}(\Gamma)$ are

\[
\begin{align*}
    s(d, (x_1, x_2)) &= (s(d), s(x_1, x_2)) = (s(d), x_1) \\
    t(d, (x_1, x_2)) &= (t(d), t(x_1, x_2)) = (t(d), x_2)
\end{align*}
\]

Let us note that $q^D_1(x_1, x_2) = x_1^{-1}x_2$, so $q^D_1(x_1, x_2) = \alpha(d)$ is equivalent to $x_2 = x_1\alpha(d)$. Therefore, the mapping $j^D: D(G \times_{\ell(\Gamma)} \hat{K}(\Gamma)) \to D(G^\alpha)$ given by $j^D(d, (x_1, x_2)) = (d, x_1)$ is a bijection. Moreover $j = (j^V, j^D)$ is a morphism of graphs, because

\[
    j^V(s(d, (x_1, x_2))) = j^V(s(d, x_1)) = s(d, x_1) = s(j^D(d, (x_1, x_2))).
\]

and

\[
    j^V(t(d, (x_1, x_2))) = j^V(t(d), x_2) = (t(d), x_2) = (t(d), x_1\alpha(d)) = t(d, x_1) = t(j^D(d, (x_1, x_2))).
\]

It remains to prove that the graph isomorphism $j$ preserves voltages and is thus a morphism in $\textbf{Volt}$. The voltage of a dart $(d, (x_1, x_2))$ of $LR(G, \Gamma, \alpha)$ is equal to

\[
    q^V_1(\alpha)(d, (x_1, x_2)) = q^V_1(x_1, x_2) = \alpha(d) = \alpha'(d, x_1) = \alpha'(j^D(d, (x_1, x_2))).
\]

Let us collect some consequences of Theorem 3.5.

Using Corollary 2.6 we may construct a product of a pair of voltage graphs $(G_1, \Gamma_1, \alpha_1), (G_2, \Gamma_2, \alpha_2)$ in $\textbf{Volt}$ as the voltage graph $(G_1 \times G_2, \Gamma_1 \times \Gamma_2, \alpha_1 \times \alpha_2)$, where $(\alpha_1 \times \alpha_2)(d_1, d_2) = (\alpha_1(d_1), \alpha_2(d_2))$. Due to Corollary 2.4 the products in $\textbf{Lab}$ can be described similarly.

**Corollary 3.6.** Let $(G_1, \Gamma_1, \alpha_1), (G_2, \Gamma_2, \alpha_2)$ be voltage graphs. Then

\[
    G_1^{\alpha_1} \times G_2^{\alpha_2} \simeq (G_1 \times G_2)^{\alpha_1 \times \alpha_2}.
\]

**Proof.** Let us compute

\[
    R((G_1, \Gamma_1, \alpha_1) \times (G_2, \Gamma_2, \alpha_2)) \simeq R(G_1 \times G_2, \alpha_1 \times \alpha_2, \Gamma_1 \times \Gamma_2) \simeq
\]

\[
    ((G_1 \times G_2)^{\alpha_1 \times \alpha_2}, \Gamma_1 \times \Gamma_2, q^V_1 \times q^V_2(\alpha_1 \times \alpha_2))
\]

Since $R$ is a right adjoint functor, it preserves limits, therefore

\[
    R((G_1, \Gamma_1, \alpha_1) \times (G_2, \Gamma_2, \alpha_2)) \simeq R(G_1, \Gamma_1, \alpha_1) \times R(G_2, \Gamma_2, \alpha_2) \simeq
\]

\[
    (G_1^{\alpha_1}, \Gamma_1, q^V_1(\alpha_1)) \times (G_2^{\alpha_2}, \Gamma_2, q^V_2(\alpha_2)) \simeq (G_1^{\alpha_1} \times G_2^{\alpha_2}, \Gamma_1 \times \Gamma_2, q^V_1(\alpha_1) \times q^V_2(\alpha_2)).
\]

A nice characterization of a fibration using pullback can be found in [1] (the authors attribute this observation to Frank Piessens) a morphism $f: G \to G'$ is a fibration if and only if the square

\[
\begin{array}{ccc}
    D(G) & \xrightarrow{\imath} & V(G) \\
    \downarrow f^D & & \downarrow f^V \\
    D(G') & \xrightarrow{\imath'} & V(G')
\end{array}
\]

is a pullback in $\textbf{Set}$. The proof of the following theorem is then an easy consequence of the so-called *two-pullbacks lemma*. 
Theorem 3.7. [1, Theorem 45] A pullback of a fibration in Graph along an arbitrary morphism is a fibration.

From this, we obtain a new proof of the fact that the canonical projection $p_\alpha: G^\alpha \to G$ is a covering.

Proof of Proposition 2.9. By Theorem 3.5, $G^\alpha$ is isomorphic to the pullback $G \times _{\ell(\Gamma)} \hat{K}(\Gamma)$. The morphism $q_\Gamma: \hat{K}(\Gamma) \to \ell(\Gamma)$ is a fibration and it is clear that $p$ is isomorphic to $\alpha^*(q_\Gamma): G \times _{\ell(\Gamma)} \hat{K}(\Gamma) \to G$. By Theorem 3.7 $p$ is then a fibration. Clearly, $p^V$ is surjective, so $p$ is a covering. □

4. Conclusion

Let us outline a possible direction for future research, concerning the voltage graphs and the voltage graph lift construction.

4.1. Group actions instead of groups. For every group $\Gamma$, one can construct the category $\text{Act}(\Gamma)$ of all actions of $\Gamma$ on sets, equipped with equivariant maps. Moreover, for every morphism of groups $h: \Gamma_1 \to \Gamma_2$ there is an obviously defined functor $\text{Act}(h): \text{Act}(\Gamma_2) \to \text{Act}(\Gamma_1)$ and this gives us a functor $\text{Act}: \text{Grp}^{op} \to \text{Cat}$.

Let us mention that the categories $\text{Act}(\Gamma)$ are sometimes called permutational categories [12] and figure prominently in the theory of cellular embeddings of graphs [13, 6].

From the functor $\text{Act}$, we may construct the category $\int \text{Act}$ of all group actions on sets, via the Grothendieck construction.

In this context, the $\hat{K}$ functor then naturally generalizes to the action groupoid $\Gamma$ of a given group action $\circ: X \times \Gamma \to X$, considered as a graph. The morphism $q_\Gamma$ can be generalized to a morphism $q_{(X, \Gamma, \circ)}$ (an interested reader can fill in the details here).

The pullback of a voltage $\alpha: G \to \ell(\Gamma)$ along the $q_{(X, \Gamma, \circ)}$ morphism is then a generalization of the permutation voltage graph lift construction [9], sometimes called a voltage space [15]. It seems that this more general construction arises from an adjunction, as well.

4.2. Bifibrational viewpoint. The obvious projection functors $\text{Volt} \to \text{Grp}$ and $\text{Lab} \to \text{Grp}$ arise as a pullback (in the category of all categories) of the codomain fibration

$$\text{cod}: \text{Graph} \to \text{Graph}$$

along the functors $\hat{K}$ and $\ell$. Therefore, both projection functors are Grothendieck fibrations. It is easy to prove that the functors are cofibrations as well. In this context, it would be interesting to examine the properties of the $q$ transformation. One could then attempt to apply the well established theory of indexed categories/fibrations [11] and possibly even categorical logic to better understand the voltage graph lifts.

Acknowledgements. The author is indebted to both anonymous referees for their valuable comments that helped to improve the paper.
