The 43-kDa TAR DNA-binding protein (TDP-43) is known to be a major component of the ubiquitinated inclusions characteristic of amyotrophic lateral sclerosis and frontotemporal lobar degeneration with ubiquitin-positive inclusions. Although TDP-43 is a nuclear protein, it disappears from the nucleus of affected neurons and glial cells, implicating TDP-43 loss of function in the pathogenesis of neurodegeneration. Here we show that the knockdown of TDP-43 in differentiated Neuro-2a cells inhibited neurite outgrowth and induced cell death. In knockdown cells, the Rho family members RhoA, Rac1, and Cdc42 GTPases were inactivated, and membrane localization of these molecules was reduced. In addition, TDP-43 depletion significantly suppressed protein geranylgeranylation, a key regulating factor of Rho family activity and intracellular localization. In contrast, overexpression of TDP-43 mitigated the cellular damage caused by pharmacological inhibition of geranylgeranylation. Furthermore administration of geranylgeranyl pyrophosphate partially restored cell viability and neurite outgrowth in TDP-43 knockdown cells. In summary, our data suggest that TDP-43 plays a key role in the maintenance of neuronal cell morphology and survival possibly through protein geranylgeranylation of Rho family GTPases.

The 43-kDa TAR DNA-binding protein (TDP-43)‡ has recently been identified as a major component of the ubiquitinated inclusions characteristic of amyotrophic lateral sclerosis (ALS) and frontotemporal lobar degeneration with ubiquitin-positive inclusions (1, 2). Subsequently several point mutations located in the glycine-rich domain of TDP-43 have been identified as the disease-causing mutations of familial and sporadic ALS (3–7). TDP-43 has been shown to be a fundamental component of ubiquitin-positive neuronal cytoplasmic and intranuclear inclusions as well as that of neuronal dystrophic neurites in the affected neurons or glial cells in these neurodegenerative diseases. TDP-43 is known to regulate gene transcription, exon splicing, and exon inclusion through interactions with RNA, heterogeneous nuclear ribonucleoproteins, and nuclear bodies (8–12). Recently it has been reported that TDP-43 stabilizes human low molecular weight neurofilament mRNAs through direct interaction with the 3′-untranslated region (13) and that it regulates retinoblastoma protein phosphorylation through the repression of cyclin-dependent kinase 6 expression (14). However, the physiological function of TDP-43 in the central nervous system has not been fully elucidated, and it remains unclear how this protein is implicated in the pathogenesis of neurodegeneration.

The Rho family of GTPases are members of the Ras superfamily and are known for regulating actin cytoskeletal dynamics (15–18). RhoA, Rac1, and Cdc42, the most studied proteins of this family, also modulate functions such as cell movement, motility, transcription, cell growth, and cell survival (18). In neurons, RhoA, Rac1, and Cdc42 have been shown to regulate neurite outgrowth (19–21). Although TDP-43 is localized in the nucleus of unaffected neurons, nuclear staining of this protein is significantly reduced in neurons bearing ubiquitin inclusions (1, 2, 22), suggesting that loss of TDP-43 function may play a role in neurodegeneration. In this study, we used small interfering RNA (siRNA) to investigate the effect of TDP-43 loss of function on cell death and neurite outgrowth and elucidated a novel relation between TDP-43 and the activities of RhoA, Rac1, and Cdc42.

EXPERIMENTAL PROCEDURES

siRNA Oligonucleotides and Construction of Expression Vectors—The oligonucleotide siRNA duplex was synthesized by Takara Bio (Shiga, Japan). The siRNA sequences were as follows: scrambled (control) siRNA-set1, 5′-GAAUCAGAUGCAUGAGUTT-3′; -set2, 5′-ACGGCCUAACUCAACAGACTT-3′; -TDP-43 siRNA-set1, 5′-GAAUCAGAUGCAUGAGATT-3′; -set2, 5′-CCAAUCGUAAACCUAAGCAT-3′. Unless otherwise mentioned, set 1 siRNA was used for TDP-43 knockdown throughout the experiments.

The pEGFP-Rac1 construct was produced as described elsewhere (23, 24). Mouse TDP-43 (GenBank™ accession number NM_145556) cDNA was amplified by PCR from mouse brain cDNA using the following primers: 5′-GTGCTTCTCCTGTTTGCTTC-3′ and 5′-CCACACTGAAACAAACATCCTG-3′. The PCR product was cloned into the pCR-BluntII-TOPO vector (Invitrogen), and the entire coding region of mouse TDP-43 was inserted in-frame into either the KpnI and XbaI sites of the pcDNA3.1/V5His vector (Invitrogen) or the KpnI and BamHI sites of the pDsRed-Monomer-Hyg-N1 vector (Clontech). An siRNA-resistant form of the TDP-43 gene was generated by changing the targeted sequence of the siRNA to 5′-GAATGACGAGGCCAATTGAAA-3′ (mutated nucleotides are underlined) using the KOD-Plus-Mutagenesis kit (Toyobo, Osaka, Japan).

Cell Culture and Transfection—Neuro-2a cells (American Type Culture Collection, Manassas, VA), a line derived from mouse neuroblastoma, were maintained as described previously (25). The transfection of siRNA into Neuro-2a cells was performed using Lipofectamine RNAiMAX (Invitrogen) according to the manufacturer’s instructions. For the transfection of the intended plasmid and siRNA, cells were co-transfected using Lipofectamine 2000 (Invitrogen) according to the manufacturer’s instructions. To differentiate the Neuro-2a cells, the medium was changed to Dulbecco’s modified Eagle’s medium containing 2% fetal calf serum and 20 μM retinoic acid, and cells were cultured for 24 h. For the interventional studies, the cells were incubated for 24 h with differentiation medium containing Clostridium difficile toxin B (Sigma-Aldrich) or for 12 h with medium containing GGTI-298 (Calbiochem). Geranylgeranyl pyrophosphate (GGPP) (Sigma-Aldrich) was added to the differentiation medium at the indicated concentration 24 h after siRNA transfection, and cells were incubated for an additional 24 h.

Quantitative Assessment of Neurite Outgrowth—Neuro-2a cells cultured in 6-well dishes were photographed using an Olympus IX71 inverted phase-contrast microscope (Olympus, Tokyo, Japan). The length of the longest neurite was measured with Image Gauge version 4.22 software (Fujifilm, Tokyo, Japan). Averages of the lengths of over 100 transfected cells were calculated. To confirm the efficacy of siRNA transfection, Japan). Averages of the lengths of over 100 transfected cells were analyzed. To confirm the efficacy of siRNA transfection, the cells were incubated for an additional 24 h. For the interventional studies, the cells were incubated for 24 h with differentiation medium containing Clostridium difficile toxin B (Sigma-Aldrich) or for 12 h with medium containing GGTI-298 (Calbiochem). Geranylgeranyl pyrophosphate (GGPP) (Sigma-Aldrich) was added to the differentiation medium at the indicated concentration 24 h after siRNA transfection, and cells were incubated for an additional 24 h.

Cell Viability and Apoptosis Analysis—The 3-(4,5-dimethyl-thiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulphophenyl)-2H-tetrazolium (MTS)-based cell proliferation assay was carried out on the differentiated Neuro-2a cells 48 h post-transfection using the CellTiter 96 Aqueous One Solution Cell Proliferation Assay (Promega, Madison, WI) according to the manufacturer’s instructions. Absorbance at 490 nm was measured in a multiple plate reader (PowescanHT, Dainippon Pharmaceutical). The assays were carried out in 6 wells for each condition. To assess cell apoptosis, differentiated Neuro-2a cells were stained with Alexa Fluor 488-conjugated Annexin V and with propidium iodide (PI) using the Vybrant Apoptosis Assay kit (Invitrogen) according to the manufacturer’s instructions. TUNEL assays were performed using the APO-DIRECT™ kit (BD Biosciences). The extent of staining in 10,000 cells was monitored by FACScalibur™ and CellQuest version 3.1.3 acquisition and analysis software (BD Biosciences) immediately after the staining.

Caspase-3/7 Assay—Neuro-2a cells were grown on black 96-well plates. The caspase-3/7 activity of differentiated Neuro-2a cells was analyzed using the Apo-ONE homogeneous caspase-3/7 assay (Promega) after 48 h of transfection or intended treatment according to the manufacturer’s instructions. Fluorescence (485/528 nm) was measured in the multiple plate reader, and the assay was carried out in 6 wells for each condition.

Quantitative Real Time PCR—mRNA levels were determined by real time PCR as described before (26). Briefly total RNA from Neuro-2a cells was reverse transcribed into first strand cDNA, real time PCR was performed, and the product was detected by the iCycler system (Bio-Rad). For an internal standard control, the expression level of glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was simultaneously quantified. The following primers were used: 5′-CCGCTATGTCAGCCAAATTGAAA-3′ and 5′-ACCAGAATTGCCTCCAACACAG-3′ for TDP-43 and 5′-TGTTTCCGTCTGGAGATCTGA-3′ and 5′-TTGCTTGTGAAGTGCAGAGGAG-3′ for GAPDH.

Western Blot Analysis—Western blot analyses were performed as described before (27). Briefly Neuro-2a cells were lysed in Celllytic lysis buffer (Sigma-Aldrich) containing a protease inhibitor mixture (Roche Applied Science) 48 h after transfection. For subcellular fractionation, we used the Proteo-Extract Subcellular Proteome Extraction kit (Calbiochem) according to the manufacturer’s instructions. Cell lysates were separated by SDS-PAGE (5–20% gradient gel) and analyzed by Western blotting with ECL Plus detection reagents (GE Healthcare). Primary antibodies used were as follows: anti-TDP-43 rabbit polyclonal antibody (1:1000; ProteinTech, Chicago, IL), anti-Rac1 mouse monoclonal antibody (1:1000; Millipore, Temecula, CA), anti-RhoA mouse monoclonal antibody (1:1000; Cytoskeleton, Denver, CO), anti-Cdc42 rabbit polyclonal antibody (1:1000; Santa Cruz Biotechnology, Santa Cruz, CA), anti-phospho-myosin phosphatase targeting subunit 1 (Thr-853) rabbit polyclonal antibody (1:500; Millipore), antomyosin phosphatase targeting subunit 1 rabbit polyclonal antibody (1:1000; Santa Cruz Biotechnology), anti-H-Ras rabbit polyclonal antibody (1:1000; Santa Cruz Biotechnology), anti-Rab5 rabbit polyclonal antibody (1:1000; Santa Cruz Biotechnology), anti-GAPDH mouse monoclonal antibody (1:1000; BD Pharmingen) as a cytosol marker, anti-integrin β1 rabbit polyclonal antibody (1:1000; Santa Cruz Biotechnology) as a membrane marker, anti-green fluorescent protein mouse monoclonal antibody (1:2000; Millipore), anti-Rho GDP dissociation inhibitor rabbit polyclonal antibody (1:1000; Millipore), anti-geranylgeranyltransferase-1B mouse polyclonal antibody (1:1000; Abnova, Taipei, Taiwan), and anti-geranylgeranyl pyrophosphate synthase rabbit polyclonal antibody (1:1000; Abgent, San Diego, CA).
**RESULTS**

**TDP-43 Depletion Induces Cell Death and Inhibits Neurite Outgrowth**—To analyze the effect of TDP-43 depletion, two sets of siRNA oligonucleotides were transfected into Neuro-2a cells. The efficiency of TDP-43 siRNA transfection was confirmed by Western blotting and quantitative real time RT-PCR (Fig. 1A and B). To assess cell viability, we carried out an MTS-based cell proliferation assay in differentiated Neuro-2a cells after 48 h of siRNA transfection. The viability of knockdown cells was significantly decreased by both sets of siRNA compared with each control (Fig. 1C). To exclude the possibility of an off-target effect, a plasmid carrying an siRNA-resistant form of TDP-43 was co-transfected together with set 1 siRNA.

**Dysregulation of Rho Families by TDP-43 Depletion**

**Rho Family GTPase Activation Analysis**—To measure RhoA and Rac1/Cdc42 GTPase activities, we used the Rho binding domain (RBD) of the Rho effector protein with Rhotekin and Cdc42/Rac interactive binding (CRIB) region of the Cdc42/Rac effector protein with p21 activated kinase 1 (PAK), respectively. Pulldown assays were performed in the presence of glutathione S-transferase-tagged Rhotekin-RBD and PAK-CRIB protein-agarose beads (Cytoskeleton) according to the manufacturer’s instructions.

**Fluorescent Images of Neuro-2a Cells**—Neuro-2a cells, which were transfected with EGFP-Rac1, DsRed-TDP-43, and siRNA (TDP-43 siRNA or control RNA), were fixed by 4% paraformaldehyde with 0.1% Triton X-100 for extraction of cytosol components. After washing, samples were mounted with VECTASHIELD mounting medium (Vector Laboratories, Inc., Burlingame, CA) and then photographed with a Zeiss Axio Imager M1 (Carl Zeiss AG).

**Assay of Protein Geranylgeranylation**—Neuro-2a cells were transfected with siRNA on 10-cm² dishes. Twenty-four hours after the transfection, 20 μM lovastatin (Sigma) was added to the culture medium. Twenty-four hours after the addition of lovastatin, the cells were labeled by adding fresh culture medium containing 6.25 μCi/ml [14C]mevalonolactone (50–62 mCi/mmol) (GE Healthcare) and 20 μl lovastatin. Nineteen hours after labeling, the cells were harvested, and Rac1 was immunoprecipitated by incubating with 4 μg of anti-RhoA mouse monoclonal antibody (Santa Cruz Biotechnology) or anti-Rac1 mouse monoclonal antibody (Millipore) for 24 h followed by adding 20 μl of protein G-Sepharose (GE Healthcare). Immunoprecipitated proteins were separated by electrophoresis on a polyacrylamide-SDS gel. The 14C-labeled gels were fixed and soaked in Amplify Fluorographic Reagent (GE Healthcare) for 30 min. The gels were dried, and labeled proteins were visualized on a Typhoon 9410 Workstation (GE Healthcare) after exposure to a Storage Phosphor Screen (GE Healthcare) for 72 h. We validated this experiment using 20 μM GGTTI-298.

**Statistical Analysis**—Statistical differences (not including neurite length data) were analyzed by analysis of variance and Bonferroni post hoc analyses for three or more group comparisons and the unpaired Student’s t test for two-group comparisons. Neurite length differences were analyzed using the Mann-Whitney U test (SPSS version 15.0, SPSS Inc., Chicago, IL). Two-tailed \( p < 0.05 \) was regarded as statistically significant.

As a result, the siRNA-resistant form of TDP-43 prevented the reduction of cell viability (Fig. 1D). The apoptotic process was quantified with Annexin V/PI staining and TUNEL labeling. The knockdown of TDP-43 significantly increased the number of PI-positive cells (Fig. 2A). However, the number of cells positive for Annexin V or TUNEL was not altered (Fig. 2, B and C). In the caspase-3/7 assay, there was no significant difference between knockdown and control cells (Fig. 2D). To clarify the effects of TDP-43 depletion on cellular morphology, we performed a time course experiment measuring the average length of neurites. Neurites of control cells extended over the course of 48 h, but neurite outgrowth was significantly inhibited in TDP-43-depleted cells (Fig. 2E).
Knockdown of TDP-43 reduces Rho family GTPase activity—To elucidate the pathophysiology of neuronal cell death and the morphological alteration caused by TDP-43 depletion, we focused on the Rho family GTPases, which are potent regulators of neurite outgrowth and cell survival. First RhoA, Rac1, and Cdc42 GTPase activities were investigated by pulldown assays. In TDP-43-depleted cells, the activities of RhoA, Rac1, and Cdc42 GTPase were all decreased compared with the controls (Fig. 3, A and B). Inactivation of RhoA GTPase was also confirmed by a significant reduction in the level of the Thr-853 phosphorylation of myosin phosphatase targeting subunit 1, which is exclusively phosphorylated by Rho kinase (28) (Fig. 3A). To verify that inactivation of Rho family GTPases leads to neuronal damage, we tested the effects of C. difficile toxin B, a pan-inhibitor of Rho family proteins, on differentiated Neuro-2a cells. As a result, this toxin reduced cell viability and inhibited neurite outgrowth (Fig. 3, C and D).

Small G proteins, including Rho and Ras family members, must be able to localize at the cell membrane to exert their biological functions (29). We thus investigated the intracellular distribution of Rho family proteins to elucidate the mechanism by which TDP-43 regulates their GTPase activity. Western blots showed that the amounts of RhoA, Rac1, and Cdc42, but not H-Ras or Rab5, in the membrane fractions were decreased in the TDP-43 knockdown cells (Fig. 4A). The subcellular fraction of Rho GDP dissociation inhibitor, another regulator of Rho activity, was not altered by TDP-43 knockdown (Fig. 4A). The siRNA-resistant form of TDP-43 rescued the reduction in the amount of membrane-bound Rho family GTPases (Fig. 4B). The fluorescent images also demonstrated that membrane-localized Rac1 was significantly reduced in TDP-43 knockdown cells in comparison with control cells (Fig. 5).

TDP-43 regulates Rho GTPase activity via protein geranylgeranylation—For membrane localization to occur, members of the Rho family of GTPases have to be catalyzed by transferring GGPP to the C-terminal motif (geranylgeranylation), whereas Ras family members, such as H-Ras, require farnesyl pyrophosphate. We thus tested two agents that modulate geranylgeranylation of Rho family molecules. GGTI-298, a specific inhibitor of geranylgeranylation, has been shown to increase neural cell death through the inactivation of Rho family GTPases (30, 31). In differentiated Neuro-2a cells, GGTI-298 inhibited neurite outgrowth and reduced cell viability in a dose-dependent manner without any evidence of caspase-3/7 activation (Fig. 6, A–C). GGTI-298 also decreased the amount of membrane-bound Rho family GTPases (Fig. 6, D).
bound Rho GTPases (Fig. 6D). In contrast, GGPP, the final substrate of geranylgeranylation, prevented the reduction in the amounts of membrane-bound RhoA, Rac1, and Cdc42 caused by TDP-43 knockdown (Fig. 6E). In addition, GGPP restored viability and neurite outgrowth in TDP-43-depleted cells (Fig. 6, F and G). These findings indicate that impaired geranylgeranylation appears to be the molecular basis of TDP-43 depletion-induced cellular damage. We next examined whether TDP-43 regulates geranylgeranylation of Rho GTPases. Fig. 7, A–C, shows that TDP-43 increased the amount of membrane-bound Rho GTPases, augmented neurite outgrowth, and increased cell viability in GGTT-298-treated cells.

Taken together, these observations suggest that TDP-43 regulates the activities of Rho family members through protein geranylgeranylation. We thus investigated the effect of TDP-43 depletion on protein geranylgeranylation using [14C]mevalonic acid (MVA). Incorporation of [14C]MVA into RhoA or Rac1 was significantly decreased in the TDP-43-depleted Neuro-2a cells (Fig. 8, A and B), suggesting that the knockdown of TDP-43 inhibits geranylgeranylation of Rho family members. GGTT-298 reduced incorporation of [14C]MVA into Rac1, further confirming this conclusion (Fig. 8C).

Protein geranylgeranylation of the Rho family is regulated by specific enzymes: geranylgeranyltransferase-Iβ and geranylgeranyl pyrophosphate synthase-1, which is responsible for synthesis of GGPP. We therefore investigated the expression levels of these enzymes. However, the knockdown of TDP-43 did not alter the protein expression level of geranylgeranyltransferase-Iβ or geranylgeranyl pyrophosphate synthase-1 (data not shown).
DISCUSSION

TDP-43 as a Regulator of Rho Family GTPases—In the present study, we demonstrated that knockdown of TDP-43 inhibits neurite outgrowth and induces cell death in differentiated Neuro-2a cells, suggesting that loss of TDP-43 function plays a causative role in neurodegeneration. To elucidate the molecular mechanisms by which TDP-43 depletion causes neuronal cell damage, we examined the relationship between TDP-43 and Rho family GTPases. Neuronal morphology is determined in large part through the regulation of the cytoskeleton. One of the key regulators of the actin cytoskeleton is the Rho family of GTPases: RhoA, Rac1, and Cdc42 (15–17). Although each Rho

Inhibited Protein Geranylgeranylation of Rho Family Members in TDP-43-depleted Cells—How does TDP-43 regulate the activities of the Rho family? Various molecules have been shown to regulate the activity of Rho, Rac, and Cdc42, but few are capable of regulating all three GTPases concomitantly. To elucidate the molecular mechanism by which TDP-43 regulates Rho, Rac, and Cdc42, we directed our attention to the fact that membrane localization is the key regulatory factor common to these molecules. Small G proteins, including members of the Rho and Ras families, act as molecular switches cycling between an active, GTP-bound state and an inactive, GDP-bound state (18, 38, 39). Post-translational modification with a C-terminal prenyl moiety allows small G proteins to associate with the membrane where they can interact with and activate their effectors (29). Proteins that require prenylation include the farnesyl group, such as the Ras family, and the geranylgeranyl group, such as the Rho or the Rab family (29, 40). In the present study, we showed that knockdown of TDP-43 decreased membrane-bound RhoA, Rac1, and Cdc42 but did not affect the intracellular distribution of H-Ras or Rab5. TDP-43 knockdown also inhibited the incorporation of [14C]MVA, a tracer of the mevalonate pathway, into RhoA and Rac1 in differentiated Neuro-2a cells. In contrast, the expression level of Rho GDP dissociation inhibitor, which functions by extracting Rho family GTPases from membranes and solubilizing them in the cytosol (41, 42), was not significantly altered by TDP-43 knockdown. In addition, inhibition of geranylgeranylation by GGTI-298 reproduced the cytotoxic effects of TDP-43 depletion, whereas GGPP, the substrate of the geranylgeranylation pathway, restored cell viability and neurite outgrowth in TDP-43-depleted Neuro-2a cells. Furthermore in GGTI-298 treated cells, overexpression of TDP-43 restored the membrane localization of Rho GTPases as well as cell viability and neurite outgrowth. These findings suggest that TDP-43 depletion inactivates Rho family GTPases through inhibition of protein geranylgeranylation.

Protein geranylgeranylation of Rho family members is catalyzed by geranylgeranyltransferase-1 using GGPP produced by geranylgeranyl pyrophosphate synthase-1 as the substrate (43). Geranylgeranyltransferase-1 consists of two subunits, α and β, and the α subunit is also a component of protein farnesyltransferase (44). We thus assessed the mRNA and protein expression of geranylgeranyltransferase-1β and geranylgeranyl pyrophosphate synthase-1 in Neuro-2a cells. However, the expression levels of these enzymes were not altered by TDP-43 knockdown. These results imply that TDP-43 depletion decreases the activities of these enzymes.

Loss of TDP-43 Function in the Pathophysiology of TDP-43 Proteinopathies—Ubiquitinated cytoplasmic inclusions are a histopathological hallmark of ALS and frontotemporal lobar degeneration with ubiquitin-positive inclusions. Although the nature of these aggregates has not been fully elucidated, recent studies have identified TDP-43 as the major component of the ubiquitin-immunoreactive neuronal inclusions seen in ALS and frontotemporal lobar degeneration with ubiquitin-positive inclusions (1, 2). There has been a great deal of debate about whether loss or gain of function of TDP-43 causes neuronal dysfunction and eventual cell death. Although TDP-43 is a protein family member has a distinct effect on cell morphology and plays an important role in the regulation of neuronal survival, we demonstrated that pan-inhibition of Rho family proteins by C. difficile toxin B suppressed neurite outgrowth and reduced cell viability as reported previously (19–21, 32, 33). We demonstrated here that the activities of RhoA, Rac1, and Cdc42 were all decreased in TDP-43-depleted cells, suggesting that knockdown of TDP-43 induces inhibition of neurite outgrowth and cell death through the inactivation of Rho family GTPases. There was no evidence of apoptosis mediated by TDP-43 in Neuro-2a cells under the present conditions (Fig. 6C), although this reagent has been shown to efficiently induce apoptosis in non-neuronal cells (36, 37).

Dysregulation of Rho Families by TDP-43 Depletion

FIGURE 8. Protein prenylation of RhoA and Rac1 in Neuro-2a cells. A, Neuro-2a cells were metabolically labeled with [14C]MVA: left, Western blot with anti-RhoA or Rac1 antibody of cell lysates; right, incorporation of [14C]MVA into RhoA or Rac1. ubiquitously expressed, highly conserved nuclear protein, under the pathological conditions in ALS and frontotemporal lobar degeneration with ubiquitin-positive inclusions, TDP-43 completely disappears from the nuclei of the affected neurons (1, 2). These histopathological findings indicate that loss of nuclear TDP-43 may underlie neuronal degeneration, although it is also possible that neuronal inclusions possess cytotoxic properties. It has been reported that TDP-43 depletion leads to up-regulation of cyclin-dependent kinase 6 protein and transcript levels followed by misregulation of the cell cycle and apoptosis in cultured human epithelial cancer cells (14). In the present study, knockdown of TDP-43 inactivated Rho family GTPases and thereby induced cell death in differentiated Neuro-2a cells. Although this is not the model mimicking the dislocation of TDP-43 from the nucleus to the cytoplasm, our findings suggest that loss of function of TDP-43 may induce neuronal degeneration probably through dysregulation of Rho family GTPases.

In summary, we have demonstrated that TDP-43 depletion inhibits neurite outgrowth and induces neuronal cell death. This phenomenon possibly results from a reduced membrane localization of Rho family GTPases due to the inhibition of protein geranylation.
