Abstract
Polyphenolic phytochemicals are of particular importance to the food, pharmaceutical and cosmetics industry, because of their unique antioxidant properties. Red grape pomace is a solid waste of the wine manufacturing process and possesses a very high polyphenolic load, hence its significance as a rich and abundant residua source. However, in many instances there is a lack of analytical data regarding its polyphenolic composition. In this study, red grape pomace originating from the Greek native cultivar *Vitis vinifera var. Agiorgitiko* was efficiently extracted with 57% aqueous ethanol, which is a non-toxic and environmentally benign solvent, with the aim of obtaining a polyphenol-enriched extract. The extract was subsequently analyzed by liquid chromatography-diode array-spectrometry analysis, in order to tentatively characterize the major polyphenolics recovered. The compounds identified were a p-coumaric acid derivative, three flavonol conjugates (two glycosides and a glucuronide), along with three anthocyanin pigments that occur in grape berries. Three other major phenolics detected could not be assigned to a tentative formula and their structural elucidation merits further investigation. The data generated from this study could be used in assessing the overall polyphenolic profile of the pomace from this particular Greek, native variety, which could be of value in producing commercial formulations with high antioxidant activity.

Keywords: Antioxidants; Liquid chromatography-mass spectrometry; Polyphenols; Red grape pomace

Abbreviations: AAR, Antiradical Activity (mM TRE g⁻¹ dpw); dpw: Dry Pomace Weight (g); GAE: Gallic Acid Equivalents; RGP: Red Grape Pomace; Rt: Retention Time; TRE: Trolox Equivalents; WISW: Wine Industry Solid Wastes; Yₚ: Total Polyphenol Yield (mg GAE g⁻¹ dpw)

Introduction
Solid wastes in wine industry mainly consist of solid by-products, such as pomace and stems. The waste material may account on an average 30% (w/w) of the grapes used for wine production. Vinification wastes contain a relatively high content of polyphenolic phytochemicals [1,2], which depends on the type of grape (white or red), the part of the tissue (skins, seeds etc), as well as the processing conditions (e.g. pomace contact).

Solid wastes have attracted considerable attention as potential sources of bioactive phenolic compounds, which can be used in the pharmaceutical, cosmetics and food industry. Studies regarding WISW are mainly focused on the polyphenolic composition of seeds, which are very rich in flavanols [3-5], but red grape pomace (RGP), which is composed of seeds and skins, has also been evaluated as potential source of antioxidant polyphenols [6-9]. However, although several methods of extraction have been developed for the efficient recovery of pomace polyphenols [10], there is still a significant lack of analytical data on the polyphenolic profile of RGP originating from different cultivars. The composition of RGP is defined by the polyphenols occurring in both seeds and skins, which are mainly flavonols [11,12] anthocyanins and flavonols [13,14], although other minor constituents, such as stilbenes [15] and dihydroflavonols [16] have been reported. All these components are considered nutritionally important, since they may possess a variety of bioactivities [17]. Therefore, the investigation of the analytical polyphenolic composition of RGP is of undisputed significance in the development of tools and methodologies for extraction and final product formulation.

Because of the lack of analytical data regarding the polyphenolic composition, the scope of the present study was an examination on the polyphenolic composition of grape pomace from the native Greek variety Agiorgitiko (*Vitis vinifera sp.*). This variety is widely cultivated in the region of Peloponnese and it is the most important native species, in terms of quality wine production. The approach attempted was the examination of a polyphenol-rich pomace extract, obtained with a hydroalcoholic solution, employing liquid chromatography-diode array-spectrometry (LC-DAD-MS) analysis.

Materials and Methods

Chemicals
Folin–Ciocalteu reagent and gallic acid were from Fluka (Steinheim, Germany). Trolox®, gallic acid, and 2, 2-diphenyl-picrylhydrazyl (DPPH•) stable radical were from Merck (Darmstadt, Germany). p-Coumaric acid was from Sigma (St. Louis, MO, U.S.A.).

Vinification solid waste
RGP was from Agiorgitiko cultivar (*Vitis vinifera sp.*), obtained from a winery located in Nemea (Peloponnese). The pomace was left in contact with the fermenting must for 7 days. The material was obtained immediately after pressing the pomace, transferred to the laboratory within a few hours and stored at -40°C until used.

Extraction procedure
A suitable quantity of RGP (approx 4.5 g) was chopped into small...
pieces with a sharp, stainless steel cutter to facilitate extraction. The chopped material was ground with sea sand and a small portion of the extraction solvent, with a pestle and a mortar, and then left to macerate for 30 min in the dark. The paste formed was placed in a 100 mL conical flask with 25 mL of solvent (solvotent-to-solid ratio 5:3) and extraction was performed under stirring at 700 rpm on a magnetic stirrer for 15 min. The extract was filtered through paper filter and this procedure was repeated twice more. The extracts were then combined in a 100 mL volumetric flask and made to the volume. All extracts were centrifuged at 4,500 rpm and filtered through 0.45 μm syringe filters prior to analyses.

**Determination of total polyphenol yield (Y<sub>TP</sub>)**

Analysis was carried out employing the Folin-Ciocâlteu methodology [18]. In a 1.5-mL Eppendorf tube, 0.78 mL of distilled water, 0.02 mL of sample appropriately diluted, and 0.05 mL of Folin-Ciocâlteu reagent were added and vortexed. After exactly 1 min, 0.15 mL of aqueous sodium carbonate 20% was added, and the mixture was vortexed and allowed to stand at room temperature in the dark, for 60 min. The absorbance was read at 750 nm (A<sub>750</sub>), and the total polyphenol concentration was calculated from a calibration curve, using gallic acid as a standard. Yield in total polyphenols (Y<sub>TP</sub>) was expressed as mg gallic acid equivalents (GAE) per g of dry weight, using the following equation:

\[
Y_{TP} (mg\text{GAE g}^{-1}) = \frac{951 \times A_{750} - 1.49 \times V}{m}
\]

Where, V is the volume of the extraction medium (mL) and m the dry weight of RGP (g).

**Measurement of the antiradical activity (A<sub>AR</sub>)**

Sample (0.025 mL), appropriately diluted, was added to 0.975 mL DPPH+ solution (100 μM in methanol), and the absorbance at 515 nm was read at t=0 (A<sub>750</sub>), and t=30 min (A<sub>750</sub>). Results were expressed as Trolox equivalents (mM TRE) per g of dry weight, using the following equation:

\[
A_{AR} (mM\text{TRE g}^{-1}) = \frac{0.018 \times \% \Delta A_{515} + 0.017}{m} \times F_{D}
\]

As determined from linear regression, after plotting % ΔA<sub>515</sub> of known solutions of Trolox against concentration; where

\[
\% \Delta A_{515} = \frac{A_{515} - A_{515}}{A_{515}} \times 100
\]

m, the weight of dry material (g), and F<sub>D</sub> the dilution factor.

**Liquid chromatography-diode array-mass spectrometry (LC-DAD-MS)**

A Finnigan MAT Spectra System P4000 pump was used coupled with a UV6000LP diode array detector and a Finnigan AQA mass spectrometer. Analyses were carried out on a Superspher RP-18, 125x2 mm, 4 μm, column (Macherey-Nagel, Germany), protected by a guard column packed with the same material, and maintained at 40°C. Analyses were carried out employing electrospray ionization (ESI) at the positive ion mode, with acquisition set at collision energies of 12 and 70 eV, capillary voltage 4 kV, source voltage 45 V, detector voltage 650 V and probe temperature 400°C. Eluent (A) a nd MeOH, respectively. The flow rate was 0.33 mL min<sup>-1</sup> and the elution programme used was as follows: 0-2 min, 0% B; 2-52 min, 100% B; 52-60 min, 100% B.

**Statistical analysis**

All determinations were carried out at least in triplicate and values were averaged and given along the standard deviation (S. D.). For all statistics, SigmaPlot™ 12.0 and Microsoft Excel™ 2010 were used.

**Results and Discussion**

**Effect of solvent composition**

Ethanol percentage in the solvents used varied from 28.5 to 85.5, a range that has been previously shown to provide high yield for grape seed extraction [3,19], but also grape pomace [9] and other plant material, including olive leaves (59%) [20], black currants [21], onion peels [22] and white grape seeds, peels and stems (57%) [23]. A hydroalcoholic solution of 57% was found to be the most effective for high polyphenol recovery, as this was manifested by estimating both Y<sub>TP</sub> and A<sub>AR</sub> (Table 1). Thus the extract obtained with 57% ethanol was chosen for the examination of the analytical polyphenolic composition.

**Tentative identification of major phytochemicals**

The principal compounds detected in the extract analyzed (Figure 1) belonged to flavonol and anthocyanin classes. In particular, three flavonol and three anthocyanin conjugates were tentatively identified, along with a p-coumaric acid derivative (Figure 2). Three other substances could not be assigned to any known grape constituent and their identification merits further investigation.

| Solvent (% v/v EtOH) | Y<sub>TP</sub> (mg GAE g<sup>-1</sup> dpw) | A<sub>AR</sub> (mM TRE g<sup>-1</sup> dpw) |
|----------------------|----------------------------------------|--------------------------------------|
| 28.5                 | 25.46 ± 2.40                          | 2.15 ± 0.09                          |
| 57.0                 | 72.59 ± 2.21                          | 2.67 ± 0.10                          |
| 85.5                 | 48.17 ± 4.07                          | 1.89 ± 0.04                          |

**Table 1:** Values determined for Y<sub>TP</sub> and A<sub>AR</sub> of the extracts obtained using aqueous solvents with varying amounts of EtOH.

diversification, which depends on several factors, such as genetic (varietal) potential, treatment, post-disposal handling etc. Therefore, the examination of such waste materials from various sources might reveal the occurrence of a spectrum of substances. In the study presented herein, red grape pomace originating from the Greek native cultivar V. vinifera var. Agiorgitiko was efficiently extracted with 57\% aqueous ethanol, to retrieve polyphenolic compounds. Ten principal polyphenols were detected and seven of them were tentatively identified on the basis of UV-vis and mass spectral data. The analyses revealed that the substances detected were a phenylpropanoid, derivative of p-coumaric acid, as well as anthocyanin pigments and flavonol glycoconjugates. Further research is needed to better illuminate the complex composition of this particular food industry by-product.
