EVALUATION OF GAUSSIAN HYPERGEOMETRIC SERIES USING HUFF’S MODELS OF ELLIPTIC CURVES

MOHAMMAD SADEK, NERMINE EL-SISSI, ARMAN SHAMSI ZARGAR, AND NASER ZAMANI

Abstract. A Huff curve over a field $K$ is an elliptic curve defined by the equation $ax(y^2 - 1) = by(x^2 - 1)$ where $a, b \in K$ are such that $a^2 \neq b^2$. In a similar fashion, a general Huff curve over $K$ is described by the equation $x(ay^2 - 1) = y(bx^2 - 1)$ where $a, b \in K$ are such that $ab(a - b) \neq 0$. In this note we express the number of rational points on these curves over a finite field $\mathbb{F}_q$ of odd characteristic in terms of Gaussian hypergeometric series

$$2F1(\lambda) := \frac{\phi}{\phi} \bigg| \frac{\epsilon}{\epsilon} \bigg| \frac{\lambda}{\lambda}$$

where $\phi$ and $\epsilon$ are the quadratic and trivial characters over $\mathbb{F}_q$, respectively. Consequently, we exhibit the number of rational points on the elliptic curves $y^2 = x(x+a)(x+b)$ over $\mathbb{F}_q$ in terms of $2F1(\lambda)$. This generalizes earlier known formulas for Legendre, Clausen and Edwards curves. Furthermore, using these expressions we display several transformations of $2F1$. Finally, we present the exact value of $2F1(\lambda)$ for different $\lambda$’s over a prime field $\mathbb{F}_p$ extending previous results of Greene and Ono.

Keywords: Elliptic curves; Huff curves; Gaussian hypergeometric functions; rational points.

1. Introduction

An elliptic curve $E$ over a field $K$ is a smooth projective curve of genus 1 equipped with a $K$-rational point. When embedded in the projective plane, $E$ can be described by a Weierstrass equation of the form

$$E: y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6$$

where $a_1, a_2, a_3, a_4, a_6 \in K$. Elliptic curves can be represented by several other equations. The interested reader may consult [15, Chapter 2]. In the few past decades, many alternative equations describing $E$ have been introduced due to cryptographic applications. In the cryptographic settings, curves are usually considered over finite fields $\mathbb{F}_q$ with $q$ elements.

Studying rational points of elliptic curves over $\mathbb{F}_q$ traces back to Gauss [13, Page 68], [14, Page 2]. In addition, finding the number of rational points of an elliptic curve over a given finite field $\mathbb{F}_q$ has always been of interest to many researchers. Schoof [10] gives three algorithms that compute the number of these rational points. This motivates cryptographers to present practical algorithms to enumerate points on higher genus curves, see [5].

Mathematics Subject Classification: 11D45, 11G20, 11T24, 14H52
Greene [4] initiated the study of Gaussian hypergeometric series over finite fields. This was followed by the work of Ono attempting to link the number of rational points on elliptic curves described by Legendre equations over finite fields with certain values of these Gaussian hypergeometric series, see [9]. Influenced by the latter articles, research has been targeting the investigation of the various links between elliptic curves described by different equations and Gaussian hypergeometric series. For example, similar links were found for Clausen curves [6] and Edwards curves [11]. Further connections between these series and the number of rational points on higher genus curves were explored, see [1, 2, 3, 12].

Herein, we consider Huff curves which are elliptic curves defined by an equation of the form

\[ H_{a,b} : ax(y^2 - 1) = by(x^2 - 1), \quad a, b \in \mathbb{F}_q^\times, \quad a^2 \neq b^2. \]

These curves were first studied by Huff to answer a Diophantine question on rational distance sets, see [7]. Huff curves were recently revisited due to the completeness of the addition law on them. This means that the formulas for the addition work for all pairs of points on Huff curves with no exceptions. This turns out to be useful for cryptographic applications, see [8]. In [16], general Huff curves were introduced. They are elliptic curves defined by the equation

\[ G_{a,b} : x(ay^2 - 1) = y(bx^2 - 1), \quad ab(a - b) \neq 0. \]

We show that the number of rational points on Huff and general Huff curves over \( \mathbb{F}_q \) can be written in terms of a Gaussian hypergeometric series of type \( {}_2F_1 \). Making use of explicit isomorphisms between Huff curves and elliptic curves with complete 2-torsion, we are able to describe the number of \( \mathbb{F}_q \)-rational points on elliptic curves described by the Weierstrass equation \( y^2 = x(x + a)(x + b) \) using Gaussian hypergeometric series \( {}_2F_1 \). This generalizes similar results of Ono on Legendre elliptic curves [9].

Exploiting the existence of an isomorphism between Huff curves and Edwards curves, we are able to find some transformations of Gaussian hypergeometric series \( {}_2F_1(\lambda) := {}_2F_1 \left( \begin{array}{c} \phi \\ \epsilon \end{array} \right| \lambda \right) \) using the counts in [11]. Additionally, these transformations are deployed to evaluate \( {}_2F_1(\lambda) \) at new values of \( \lambda \) extending on the findings of [4] and [9].

2. Preliminaries

In this note, \( p \) will be an odd prime and \( q = p^r \) for some positive integer \( r \). A multiplicative character \( \chi \) over \( \mathbb{F}_q^\times \) will be extended to be defined over \( \mathbb{F}_q \) by setting \( \chi(0) = 0 \). We will write \( \overline{\chi} \) for \( 1/\chi \). The Greek letters \( \epsilon \) and \( \phi \) are preserved for the trivial and quadratic characters respectively. More precisely, \( \epsilon(x) = 1 \) for every \( x \in \mathbb{F}_q^\times \), and \( \epsilon(0) = 0 \); whereas \( \phi(x) = 1 \) if \( x \) is a square in \( \mathbb{F}_q^\times \), \( \phi(x) = -1 \) if \( x \) is not a square, and \( \phi(0) = 0 \).
Let $J(A, B)$ be the Jacobi sum

$$J(A, B) = \sum_{x \in \mathbb{F}_q} A(x)B(1 - x)$$

where $A$ and $B$ are multiplicative characters over $\mathbb{F}_q$. Let $A_0, A_1, \ldots, A_n$ and $B_1, \ldots, B_n$ be multiplicative characters defined over $\mathbb{F}_q$. The Gaussian hypergeometric series $\,_{n+1}F_n$ is defined as follows

$$\,_{n+1}F_n \left( \begin{array}{c} A_0 & A_1 & \ldots & A_n \\ B_1 & \ldots & B_n \end{array} \right) := \frac{q}{q-1} \sum_{x \in \mathbb{F}_q} \left( \begin{array}{c} A_0 \chi \\ x \end{array} \right) \left( \begin{array}{c} A_1 \chi \\ B_1 \chi \end{array} \right) \cdots \left( \begin{array}{c} A_n \chi \\ B_n \chi \end{array} \right) \chi(x)$$

where the sum is over all multiplicative characters over $\mathbb{F}_q$ and

$$\left( \begin{array}{c} A \\ B \end{array} \right) := \frac{B(-1)}{q} J(A, B) = \frac{B(-1)}{q} \sum_{x \in \mathbb{F}_q} A(x)B(1 - x).$$

The following lemma contains some of the properties of the symbol $\left( \begin{array}{c} A \\ B \end{array} \right)$ that can be found in [4].

**Lemma 2.1.** Let $\epsilon$ and $\phi$ be the trivial and quadratic characters over $\mathbb{F}_q$ respectively. For any multiplicative characters $A$ and $B$ over $\mathbb{F}_q$, one has:

a) $A(1 + x) = \delta(x) + \frac{q}{q-1} \sum_{\chi} \left( \begin{array}{c} A \\ \chi \end{array} \right) \chi(x)$ where $\delta(x) = 1$ if $x = 0$ and $\delta(x) = 0$ if $x \neq 0$,

b) $\overline{A}(1 - x) = \delta(x) + \frac{q}{q-1} \sum_{\chi} \left( \begin{array}{c} A \chi \\ x \end{array} \right) \chi(x)$ where $\delta(x) = 1$ if $x = 0$ and $\delta(x) = 0$ if $x \neq 0$,

c) $\left( \begin{array}{c} A \\ B \end{array} \right) = \left( \begin{array}{c} A \\ \overline{B} \end{array} \right)$,

d) $\left( \begin{array}{c} A \\ B \end{array} \right) = \left( \begin{array}{c} B \chi \\ B \end{array} \right) B(-1)$,

e) $\left( \begin{array}{c} A \\ \epsilon \end{array} \right) = \left( \begin{array}{c} A \\ A \end{array} \right) = -\frac{1}{q} + \frac{q - 1}{q} \delta(A)$ where $\delta(A) = 1$ if $A = \epsilon$ and $\delta(A) = 0$ otherwise,

f) $\left( \begin{array}{c} B^2 \chi^2 \\ \chi \end{array} \right) = \left( \begin{array}{c} \phi B \chi \\ \chi \end{array} \right) \left( \begin{array}{c} B \chi \\ B^2 \chi \end{array} \right) \left( \begin{array}{c} \phi \\ \chi \end{array} \right)^{-1} B \chi(4)$,

g) $\left( \begin{array}{c} A^2 \\ AB \end{array} \right) = \left( \begin{array}{c} A \\ \phi A \end{array} \right) \left( \begin{array}{c} \phi \\ B \end{array} \right)^{-1} A(4).$
3. Evaluation of some character sums

In this section, we evaluate the character sums that we use in this work.

Lemma 3.1. Let $f : \mathbb{F}_q \rightarrow \mathbb{C}$ be a map. One has
\[
\sum_{x \in \mathbb{F}_q} \phi(x)f(x) = \sum_{x \in \mathbb{F}_q} f(x^2) - \sum_{x \in \mathbb{F}_q} f(x).
\]

Proof: This holds since
\[
\sum_{x \in \mathbb{F}_q} \phi(x)f(x) = \sum_{x \in \mathbb{F}_q} (1 + \phi(x))f(x) - \sum_{x \in \mathbb{F}_q} f(x).
\]
This follows because $1 + \phi(x)$ is either 2 if $x$ is a square in $\mathbb{F}_q^\times$; 1 if $x = 0$; or 0 otherwise. \qed

The following corollary can be found in [12]. We reproduce the proof for the convenience of the reader.

Corollary 3.2. Let $a \in \mathbb{F}_q^\times$ and let $\chi, \psi$ be characters on $\mathbb{F}_q$. Then
\[
\sum_{x \in \mathbb{F}_q} \psi(x^2)\chi(1 + ax^2) = \psi(-a^{-1})J(\psi, \chi) + \phi\psi(-a^{-1})J(\phi\psi, \chi).
\]

In particular, if $\chi = \phi$ then
\[
\sum_{x \in \mathbb{F}_q} \psi(x^2)\phi(1 + ax^2) = q\phi(-1) \left( \psi\left(-a^{-1}\right) \left( \psi \phi \psi \right) + \phi\psi\left(-a^{-1}\right) \left( \phi\psi \phi \psi \right) \right).
\]

Proof: By setting $f(x) = \psi(x)\chi(1 + ax)$, Lemma 3.1 implies that
\[
\sum_{x \in \mathbb{F}_q} \psi(x^2)\chi(1 + ax^2) = \sum_{x \in \mathbb{F}_q} \psi(x)\chi(1 + ax) + \sum_{x \in \mathbb{F}_q} \phi\psi(x)\chi(1 + ax).
\]
Now, since the map $x \mapsto -a^{-1}x$ is bijective over $\mathbb{F}_q$, one has
\[
\sum_{x \in \mathbb{F}_q} \psi(x^2)\chi(1 + ax^2) = \psi(-a^{-1}) \sum_{x \in \mathbb{F}_q} \psi(x)\chi(1 - x) + \phi\psi(-a^{-1}) \sum_{x \in \mathbb{F}_q} \phi\psi(x)\chi(1 - x)
\]
\[
= \psi(-a^{-1})J(\psi, \chi) + \phi\psi(-a^{-1})J(\phi\psi, \chi)
\]
where the last equality holds using the definition of the Jacobi sum. Putting $\chi = \phi$, one has
\[
\sum_{x} \psi(x^2)\phi(1 + ax^2) = \psi(-a^{-1})J(\psi, \phi) + \phi\psi(-a^{-1})J(\phi\psi, \phi)
\]
\[
= q\phi(-1) \left( \psi\left(-a^{-1}\right) \left( \psi \phi \psi \right) + \phi\psi\left(-a^{-1}\right) \left( \phi\psi \phi \psi \right) \right)
\]
where the last equality is implied by the definition of the symbol $\left( \frac{A}{B} \right)$. Now one concludes using Lemma 2.1 (c). \qed
4. Number of rational points on Huff curves

The following lemma evaluates certain symbols $\binom{A}{B}$.

**Lemma 4.1.** For any multiplicative character $\chi$ over $F_q$, one has

a) $\binom{\phi}{\chi} = \binom{\phi\chi}{\chi}(\chi(-1))$,

b) $\binom{\epsilon}{\epsilon} = \frac{q - 2}{q}$,

c) $\binom{\chi^2}{\chi} = \binom{\phi\chi}{\chi}(\phi)(\chi^4)$ if $\chi \neq \epsilon$.

**Proof:** The first equality follows directly from Lemma 2.1 (d) while the second equality follows from Lemma 2.1 (e). By setting $B = \epsilon$ in Lemma 2.1 (f), we get

$$\binom{\chi^2}{\chi} = \binom{\phi\chi}{\chi}(\chi^4)$$

Now Lemma 2.1 (e) implies that $\binom{\chi}{\chi} = \binom{\phi}{\phi} = -1/q$, if $\chi \neq \epsilon$. $\square$

A **general Huff curve** is defined by the following equation

$$G_{a,b} : x(ay^2 - 1) = y(bx^2 - 1), \ ab(a - b) \neq 0.$$  

We notice first that the curve has three points at infinity. This follows by homogenizing the defining equation via $x = X/Z$, $y = Y/Z$, so that we get the general Huff curve in the projective plane as $X(aY^2 - Z^2) = Y(bX^2 - Z^2)$. Hence, the points $(1 : 0 : 0)$, $(0 : 1 : 0)$ and $(a:b:0)$ are in $G_{a,b}(F_q)$.

The following theorem gives the number of rational points on $G_{a,b}$ over $F_q$ in terms of a hypergeometric series of type $2F_1$.

**Theorem 4.2.** Let $G_{a,b}$ be a general Huff curve defined by the equation $x(ay^2 - 1) = y(bx^2 - 1)$ where $ab(a - b) \neq 0$. Then

$$|G_{a,b}(F_q)| = q + 2 - \frac{1}{q - 1} - \left(2 + \frac{1}{q - 1}\right)\phi(a^{-1}b) + \frac{q^2}{q - 1}2F_1\left(\begin{array}{c} \phi \\ \phi \end{array} \vline \begin{array}{c} a^{-1}b \\ \epsilon \end{array}\right).$$

**Proof:** After completing the square, the curve $G_{a,b}$ is described by the equation

$$Y^2 = \frac{b^2x^4 + (4a - 2b)x^2 + 1}{4a^2x^2}, \quad x \neq 0,$$
where \( Y = y - \frac{bx^2 - 1}{2ax}, \ x \neq 0 \). In fact, there is only one point in \( G_{a,b}(\mathbb{F}_q) \) that has a zero \( x \)-coordinate. Therefore, we obtain the following equalities
\[
|G_{a,b}(\mathbb{F}_q)| = q + 3 + 1 + \sum_{x \in \mathbb{F}_q^\times} \phi \left( b^2x^4 + (4a - 2b)x^2 + 1 \right)
= q + 4 + \sum_{x \in \mathbb{F}_q^\times} \phi \left( 4ax^2 + (1 - bx^2)^2 \right)
= q + 4 + \sum_{x \in \mathbb{F}_q^\times} \phi \left( 1 + \frac{a^{-1}}{4x^2}(1 - bx^2)^2 \right).
\]

Lemma 2.1 (a) gives the following equalities
\[
|G_{a,b}(\mathbb{F}_q)| = q + 4 + \sum_{x \in \mathbb{F}_q^\times} \left\{ \frac{q}{q - 1} \sum_{\chi} \left( \frac{\phi}{\chi} \right) \chi \left( \frac{a^{-1}}{4x^2}(1 - bx^2)^2 \right) \right\}
= q + 4 + \frac{q}{q - 1} \sum_{x \in \mathbb{F}_q^\times} \sum_{\chi} \left( \frac{\phi}{\chi} \right) \chi \left( \frac{a^{-1}}{4x^2} \right) x^2(1 - bx^2)
= q + 4 + \frac{q}{q - 1} \sum_{\chi} \left( \frac{\phi}{\chi} \right) \chi \left( \frac{a^{-1}}{4} \right) \left( \sum_{x \in \mathbb{F}_q^\times} \bar{\chi}(x^2)x^2(1 - bx^2) \right).
\]

On account of Corollary 3.2, we get
\[
|G_{a,b}(\mathbb{F}_q)| = q + 4 + \frac{q}{q - 1} \sum_{\chi} \left( \frac{\phi}{\chi} \right) \chi \left( \frac{a^{-1}}{4} \right) \left[ \bar{\chi}(\varphi^{-1})J(\bar{\chi}, \chi^2) + \phi \bar{\chi}(\varphi^{-1})J(\phi \bar{\chi}, \chi^2) \right]
= q + 4 + \frac{q}{q - 1} \sum_{\chi} \left( \frac{\phi}{\chi} \right) \chi \left( \frac{a^{-1}}{4} \right) \chi(b)J(\bar{\chi}, \chi^2) + \frac{q}{q - 1} \sum_{\chi} \left( \frac{\phi}{\chi} \right) \chi \left( \frac{a^{-1}}{4} \right) \phi \chi(b)J(\phi \bar{\chi}, \chi^2).
\]

Using the identities
\[
J(\bar{\chi}, \chi^2) = J(\chi^2, \bar{\chi}) = q\bar{\chi}(-1)\left( \frac{\chi^2}{\chi} \right), \ J(\phi \bar{\chi}, \chi^2) = J(\chi^2, \phi \bar{\chi}) = q\phi \bar{\chi}(-1)\left( \frac{\chi^2}{\phi \chi} \right),
\]
we get
\[
|G_{a,b}(\mathbb{F}_q)| = q + 4 + \frac{q^2}{q - 1} \sum_{\chi} \left( \frac{\phi}{\chi} \right) \chi \left( \frac{-a^{-1}b}{4} \right) + \frac{q^2}{q - 1} \phi(-1) \sum_{\chi} \left( \frac{\phi}{\phi \chi} \right) \chi \left( \frac{-a^{-1}b}{4} \right).
\]

We note that over \( \mathbb{F}_q^\times \), we have \( \bar{\phi} = \phi \) and \( \phi^2 = 1 \).
Now Lemma 4.1 implies that

\[ |G_{a,b}(\mathbb{F}_q)| = q + 4 + \frac{q^2}{q-1} \sum_{\chi} \left( \phi \chi \right) \left( \chi^2 \right) \chi \left( \frac{a^{-1}b}{4} \right) + \frac{q^2}{q-1} \phi(-1) \sum_{\chi} \left( \phi \chi \right) \left( \chi^2 \right) \chi \left( \frac{a^{-1}b}{4} \right) \]

\[ = q + 4 + \frac{q^2}{q-1} \phi(-1) \sum_{\chi} \left( \phi \chi \right) \left( \chi \right) \left( \phi \chi \right) \left( \phi \right) \chi \left( a^{-1}b \right) \]

According to Lemma 4.1 and Lemma 2.1(g), (e), the latter equality can be written as follows

\[ |G_{a,b}(\mathbb{F}_q)| = q + 4 + \frac{q^2}{q-1} \sum_{\chi \neq \epsilon} \left( \phi \chi \right) \left( \phi \chi \right) \chi \left( a^{-1}b \right) - \frac{q^2}{q-1} \]

\[ + \frac{q^2}{q-1} \phi(-1) \sum_{\chi} \left( \phi \chi \right) \left( \chi \right) \left( \phi \chi \right) \left( \phi \right) \chi \left( a^{-1}b \right) \]

\[ = q + 3 + \frac{1}{q-1} + \frac{q^2}{q-1} \sum_{\chi \neq \epsilon} \left( \phi \chi \right) \left( \phi \chi \right) \chi \left( a^{-1}b \right) - \frac{q^2}{q-1} \phi(-1) \sum_{\chi} \left( \phi \chi \right) \left( \chi \right) \left( \phi \chi \right) \chi \left( a^{-1}b \right) \]

\[ = q + 3 + \frac{1}{q-1} + \frac{q^2}{q-1} \sum_{\chi \neq \epsilon} \left( \phi \chi \right) \left( \phi \chi \right) \chi \left( a^{-1}b \right) - \frac{q^2}{q-1} \left( \epsilon \right) \left( \phi \right) \left( \epsilon \right) \phi \left( a^{-1}b \right) \]

\[ = q + 3 + \frac{q^2}{q-1} \sum_{\chi \neq \epsilon} \left( \phi \chi \right) \left( \phi \chi \right) \chi \left( a^{-1}b \right) + \frac{q^2}{q-1} \phi(-1) \sum_{\chi \neq \epsilon} \left( \phi \chi \right) \left( \chi \right) \chi \left( a^{-1}b \right) - \frac{q^2}{q-1} \phi \left( a^{-1}b \right) \]

\[ = q + 3 + \frac{q^2}{q-1} \phi \left( a^{-1}b \right) + \frac{q^2}{q-1} \sum_{\chi} \left( \phi \chi \right) \left( \phi \chi \right) \chi \left( a^{-1}b \right) \]

\[ + \frac{q^2}{q-1} \phi(-1) \sum_{\chi} \left( \phi \chi \right) \left( \chi \right) \chi \left( a^{-1}b \right) - \frac{q^2}{q-1} \phi(-1) \left( \epsilon \right) \left( \phi \right) \phi \left( a^{-1}b \right) \]

\[ = q + 3 - \phi \left( a^{-1}b \right) + \frac{q^2}{q-1} \sum_{\chi} \left( \phi \chi \right) \left( \phi \chi \right) \chi \left( a^{-1}b \right) + \frac{q^2}{q-1} \phi(-1) \sum_{\chi} \left( \phi \chi \right) \left( \chi \right) \chi \left( a^{-1}b \right) \]

\[ = q + 3 - \phi \left( a^{-1}b \right) + \frac{q^2}{q-1} \left[ \binom{2F1}{\phi | a^{-1}b} + \phi(-1) \binom{2F1}{\phi | a^{-1}b} \right] \]
where
\[
_{\phi \epsilon}^{a^{-1}b}F_1 = -\frac{1}{q}\phi(-1) \left(1 + \phi(a^{-1}b)\right),
\]
see Corollary 3.16 of \[4\]. Therefore, one may deduce that
\[
\left|G_{a,b}(\mathbb{F}_q)\right| = q + 3 - \phi(a^{-1}b) - \frac{q}{q - 1} \left(1 + \phi(a^{-1}b)\right) + \frac{q^2}{q - 1} _{\phi \epsilon}^{a^{-1}b}F_1,
\]
The Huff curve \( H_{a,b} : ax(y^2 - 1) = by(x^2 - 1) \) is isomorphic to the elliptic curve defined by \( v^2 = u(u+a^2)(u+b^2) \). Moreover, \( E \) contains a subgroup isomorphic to \( \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z} \). Conversely, any elliptic curve with rational subgroup isomorphic to \( \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z} \) is isomorphic to a Huff curve. More specifically, \( E \) contains a subgroup isomorphic to \( \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z} \). Consequently, any elliptic curve with rational subgroup isomorphic to \( \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z} \) is isomorphic to a Huff curve. More specifically, \( E \) contains a subgroup isomorphic to \( \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z} \). For a full description of the isomorphisms above, the reader may consult [16].

Corollary 5.1. Let \( E_{a,b} \) be an elliptic curve defined by \( y^2 = x(x+a)(x+b) \) over \( \mathbb{F}_q \). Then the number of rational points in \( E(\mathbb{F}_q) \) is given as follows

\[
|E_{a,b}(\mathbb{F}_q)| = q + 2 - \frac{1}{q-1} \left( 2 \phi(a^{-1}b) + \frac{q^2}{q-1} \right) 2 F_1 \left( \frac{\phi}{\epsilon} \left| a^{-1}b \right| \right).
\]

Proof: This is given by making use of the isomorphism between the Huff curve \( G_{a,b} \) and \( E_{a,b} \), see Theorem 2.1 in [16] for an explicit description of the isomorphism. Now we use Theorem 4.2.

Furthermore, the Huff curve \( H_{a,b} \) is isomorphic to an Edwards curve described by \( E_{d^2} : x^2 + y^2 = 1 + d^2 x^2 y^2 \) where \( d = \frac{a-b}{a+b} \). In [11], the size of the rational points on an Edwards curves is expressed in terms of \( 2 F_1 \) over \( \mathbb{F}_p \). Yet, all the results there are valid over \( \mathbb{F}_q \). Thus, one gets the following.

Theorem 5.2. Let \( \lambda \neq 0, \pm 1 \) be in \( \mathbb{F}_q \). The following identities hold

\[
2 F_1(\lambda^2) = \frac{q+1}{q^2} + \frac{q-1}{q} \phi(-1) 2 F_1 \left( \frac{1-\lambda}{1+\lambda} \right)
= \frac{q+1}{q^2} + \frac{q-1}{q} 2 F_1 \left( \frac{4\lambda}{(1+\lambda)^2} \right)
= \frac{q+1}{q^2} + \frac{q-1}{q} \phi(\lambda) 2 F_1 \left( \frac{(1-\lambda)^2}{-4\lambda} \right).
\]

Proof: One knows that \( H_{a,b} \) is isomorphic to \( E_{d^2} \) over \( \mathbb{F}_q \) where \( d = (a-b)/(a+b) \). In particular, \( H_{1,\lambda} \cong E_{d^2} \) where \( d = \frac{1-\lambda}{1+\lambda} \). One obtains the following equality by using
Corollary 4.3 for $|H_{1,\lambda}(\mathbb{F}_q)|$ and [11] Theorem 4.1 for $|E_{d^2}(\mathbb{F}_q)|$

$$q - \frac{2}{q-1} + \frac{q^2}{q-1} {}_2F_1\left(\begin{array}{c} \phi, \phi \\ \epsilon \end{array} \bigg| \lambda^2 \right) = 1 + q + q\phi(-1) \cdot {}_2F_1\left(\begin{array}{c} \phi, \phi \\ \epsilon \end{array} \bigg| d^2 \right).$$

Therefore,

$${}_2F_1(\lambda^2) = \frac{q+1}{q^2} + \frac{q-1}{q} \phi(-1) {}_2F_1\left(\begin{array}{c} \left(1-\frac{1}{\lambda}\right)^2 \\ \frac{d^2}{d^2-1} \end{array} \right).$$

The other identities follow by observing that Theorem 4.4 of [4] indicates that $ {}_2F_1(d^2) = \phi(-1) {}_2F_1(1-d^2)$ and $ {}_2F_1(d^2) = \phi(1-d^2) {}_2F_1\left(\begin{array}{c} d^2 \\ d^2-1 \end{array} \right).$ \hfill $\square$

The above theorem enables us to obtain new values for $ {}_2F_1(\lambda)$. The values $ {}_2F_1(\pm 1)$, $ {}_2F_1(2)$ and $ {}_2F_1(1/2)$ are already known thanks to the works of Greene and Ono, see [4, 9]. The following result shows how one may obtain new values for $ {}_2F_1(\lambda)$.

**Theorem 5.3.** Let $p \equiv 1 \mod 4$ be a prime. Let $a \in \mathbb{F}_p$ be such that $a^2 \equiv -1 \mod p$. One has

$${}_2F_1\left(\frac{4a}{(1+a)^2} \right) = \frac{2x(-1)^{x+y+1}}{p-1} - \frac{p+1}{p(p-1)}, \quad x^2 + y^2 = p, \ x \ is \ odd.$$

Similarly, if $p \equiv \pm 1 \mod 8$, we choose a such that $a^2 \equiv 1/2 \ or \ 2 \ mod \ 8$. One has

$${}_2F_1\left(\frac{4a}{(1+a)^2} \right) = \begin{cases} \frac{p+1}{p(p-1)}, & \text{if } p \equiv -1 \mod 8; \\ \frac{2x(-1)^{x+y+1}}{p-1} - \frac{p+1}{p(p-1)}, & \text{if } p \equiv 1 \mod 8, \ x^2 + y^2 = p, \ x \ is \ odd \end{cases}$$

**Proof:** For the first part, the existence of $a$ is guaranteed by the fact that $p \equiv 1 \mod 4$. Now Theorem 5.2 implies that

$${}_2F_1\left(\frac{4a}{(1+a)^2} \right) = \frac{p}{p-1} \left( {}_2F_1(-1) - \frac{p+1}{p^2} \right)$$

$$= \frac{p}{p-1} \cdot \frac{2x(-1)^{x+y+1}}{p} - \frac{p+1}{p(p-1)}, \quad x^2 \ + \ y^2 = p, \ x \ is \ odd$$

where the last equality follows from Theorem 2 of [9]. The second part follows in a similar manner. \hfill $\square$

One may use the transformations given in Theorem 5.2 to evaluate $ {}_2F_1(\lambda)$ for other values of $\lambda$.
