5-point Toponogov theorem

Nina Lebedeva and Anton Petrunin

Abstract

We give an if-and-only-if condition on a five-point metric spaces that admit embeddings into nonnegatively curved Riemannian manifolds.

1 Introduction

Toponogov theorem provides an if-and-only-if condition on a metric on four-point space that admits an isometric embedding into a nonnegatively curved Riemannian manifold. The only-if part is proved by Toponogov, and the if part follows from a result of Abraham Wald [11, §7].

We show that the so-called Lang–Schroeder–Sturm inequality is the analogous condition for five-point spaces. The only-if part is well known, but the if part is new. In a sense, our result is negative — it was hard to imagine some new restrictions, but now we know there are none.

Let us formulate the Lang–Schroeder–Sturm inequality [4, 9]. Consider an \((n+1)\)-point array \((p, x_1, \ldots, x_n)\) in a metric space \(X\). We say that the array satisfies Lang–Schroeder–Sturm inequality with center \(p\) if for any nonnegative values \(\lambda_1, \ldots, \lambda_n\) we have

\[
\sum_{i,j} a_{ij} \cdot \lambda_i \cdot \lambda_j \geq 0,
\]

where \(a_{ij} = |p - x_i|_X^2 + |p - x_j|_X^2 - |x_i - x_j|_X^2\) and we denote by \(|p - q|_X\) the distance between points in \(X\).

Recall that any point array in a complete nonnegatively curved Riemannian manifold (and, more generally, in any nonnegatively curved Alexandrov space) meets the Lang–Schroeder–Sturm inequality [4, 9]. In particular, the Lang–Schroeder–Sturm inequalities for all relabelings of points in a finite metric space \(F\) gives a necessary condition for the existence of isometric embedding of \(F\) into a complete Riemannian manifold with nonnegative curvature. In this note, we show that this condition is sufficient if \(F\) has at most 5 points.

1.1. Theorem. A five-point metric space \(F\) admits an isometric embedding into a complete nonnegatively curved Riemannian manifold if and only if all Lang–Schroeder–Sturm inequalities hold in \(F\).

We already know that Lang–Schroeder–Sturm inequalities are necessary. It remains to construct a complete nonnegatively curved Riemannian manifold
that contains an isometric copy of any given 5-point space satisfying the assumptions. We first construct an Alexandrov space with this property and then smooth it slightly keeping the required property.

Our proof uses brute force search that was originally done on a computer. We want to thank Arseniy Akopyan and Alexander Gil who helped us with programming. We present a hand-made proof that was found later. It still based on brute force search, and we hope that a more conceptual proof will be found later. Our paper is inspired by an unpublished note of Vladimir Zolotov and the first author; the results from this note are discussed briefly in the last section.

2 LSS\((n)\) and \((n+1)\)-comparison

The \((n+1)\)-comparison is another condition that holds for any \((n+1)\)-point array in Alexandrov spaces [1, 2]. It says that given a point array \(p, x_1, \ldots, x_n\) in a nonnegatively curved Alexandrov space \(A\) there is an array \(\tilde{p}, \tilde{x}_1, \ldots, \tilde{x}_n\) in a Hilbert space \(\mathbb{H}\) such that

\[ |\tilde{p} - \tilde{x}_j|_{\mathbb{H}} = |p - x_i|_A \quad \text{and} \quad |\tilde{x}_i - \tilde{x}_j|_{\mathbb{H}} \geq |x_i - x_j|_A. \]

for all \(i\) and \(j\). The point \(p\) will be called the center of comparison.

For general metric spaces, the \((n+1)\)-comparison implies the Lang–Schroeder–Sturm inequality, briefly LSS\((n)\). For \(n \geq 5\) the converse does not hold [6, Section 8]. In this section, we will show that these two conditions are equivalent for \(n \leq 4\).

2.1. Claim. For any 5-point array \(p, x_1, \ldots, x_4\), the LSS\((4)\)-inequality is equivalent to \((4+1)\)-comparison.

Applying the claim, we get the following reformulation of the main theorem.

2.2. Reformulation. A five-point metric space \(F\) admits an isometric embedding into an Alexandrov space with nonnegative curvature if and only if it satisfies \((4+1)\)-comparison for all relabelings.

The following proof is nearly identical to the proof of Proposition 4.1 in [6].

Proof of 2.1. Suppose \(p, x_1, \ldots, x_4\) satisfies LSS\((4)\); we need to show that it also meets the \((4+1)\)-comparison.

Choose a smooth function \(\varphi: \mathbb{R} \to \mathbb{R}\) such that \(\varphi(x) = 0\) is \(x \geq 0\) and \(\varphi(x) > 0, \varphi'(x) < 0\) if \(x < 0\). Consider a configuration of points \(\tilde{p}, \tilde{x}_1, \ldots, \tilde{x}_4 \in \mathbb{H}\) such that

\[ |\tilde{p} - \tilde{x}_j|_{\mathbb{H}} = |p - x_i|_A. \]

and has minimal value

\[ s = \sum_{i<j} \varphi(|\tilde{x}_i - \tilde{x}_j|_{\mathbb{H}} - |x_i - x_j|_A). \]

Note that \(s \geq 0\); if \(s = 0\), then we get the required configuration.
Suppose $s > 0$. Consider the graph $\Gamma$ with 4 vertices labeled by $\hat{x}_1, \hat{x}_2, \hat{x}_3, \hat{x}_4$ such that $(\hat{x}_i, \hat{x}_j)$ is an edge if and only if $|\hat{x}_i - \hat{x}_j| \leq |x_i - x_j|$. By the triangle inequality, $\Gamma$ contains no end-vertices. Therefore it is isomorphic to one of four graphs on the diagram.

Without loss of generality, we can assume that $\hat{p} = 0$. Note that any point $\hat{x}_i$ cannot lie in an open half-space with all its adjacent points. Indeed, if it would be the case, then we could slightly move this vertex increasing the distances to all its adjacent vertexes; so the value $s$ will decrease—a contradiction.

In the 6-edge case, $0$ lies in the convex hull of $\{\hat{x}_1, \hat{x}_2, \hat{x}_3, \hat{x}_4\}$. In particular, we can write $0$ as a sum $\lambda_1 \cdot \hat{x}_1 + \cdots + \lambda_4 \cdot \hat{x}_4$ with $\lambda_i > 0$. The latter contradicts $LSS(4)$.

Similarly, in the 5- and 3-edge cases, we can assume that $\hat{x}_1 \hat{x}_2 \hat{x}_3$ is a 3-cycle of $\Gamma$. In this case, we can write $0$ as a sum $\lambda_1 \cdot \hat{x}_1 + \lambda_2 \cdot \hat{x}_2 + \lambda_3 \cdot \hat{x}_3$ with $\lambda_i > 0$ and arrive at a contradiction.

Finally, the 4-edge graph (the 4-cycle) cannot occur. In this case, we may think that $\hat{x}_1, \hat{x}_2, \hat{x}_3, \hat{x}_4$ is the 4-cycle. Note that the points $\hat{x}_1, \hat{x}_2, \hat{x}_3, \hat{x}_4$ lie in one plane so that the direction of $\hat{x}_1$ is opposite to $\hat{x}_3$, and the direction of $\hat{x}_2$ is opposite to $\hat{x}_4$. Let us think that this is the horizontal plane in $\mathbb{R}^3$. Then rotating the pair $\hat{x}_1, \hat{x}_3$ slightly up and the pair $\hat{x}_2, \hat{x}_4$ slightly down, decreases $s$—a contradiction.

\end{figure}

\section{Associated form}

In this section we recall a construction from [8]. Let $x = (x_1, \ldots, x_n)$ be a point array in a metric space $X$.

Choose a simplex $\Delta$ in $\mathbb{R}^{n-1}$; for example, we can take the standard simplex with the first $(n-1)$ of its vertices $v_1, \ldots, v_{n-1}$ form the standard basis on $\mathbb{R}^{n-1}$, and $v_n = 0$.

Consider a quadratic form $W_x$ on $\mathbb{R}^{n-1}$ that is uniquely defined by

$$W_x(v_i - v_j) = |x_i - x_j|^2$$

for all $i$ and $j$. It will be called the form associated to the point array $x$. The following claim is self-evident:

\begin{claim}
An array $x = (x_1, \ldots, x_n)$ with a metric is isometric to an array in a Euclidean space if and only if $W_x(v) \geq 0$ for any $v \in \mathbb{R}^{n-1}$.
\end{claim}

In particular, the condition $W_x \geq 0$ for a triple $x = (x_1, x_2, x_3)$ is equivalent to the three triangle inequalities for the distances between $x_1, x_2,$ and $x_3$. For an $n$-point array, it implies that $W_x(v) \geq 0$ for any vector $v$ in a plane spanned by a triple of vertices of $\Delta$. 

3
Lang–Schroeder–Sturm inequalities. Consider the cone $K_n \subset \mathbb{R}^{n-1}$ that contains lines $L$ that connect a point on a facet of $\Delta$ with its opposite vertex. Note that $K_3 = \mathbb{R}^2$, but for $n \geq 4$ the cone $K_n$ is a proper subset of $\mathbb{R}^{n-1}$.

The following claim is a reformulation Sturm–Lang–Shroeder inequalities for all relabeling of $x$:

3.2. Claim. Let $x = (x_1, \ldots, x_n)$ be an $n$-point array in an Alexandrov space with nonnegative curvature. Then $W_x(w) \geq 0$ for any $w \in K_n$.

4 Tense arrays

Assume $(p, x_1, \ldots, x_n)$ is an array of points with a metric that satisfies LSS($n$) with center at $p$. Suppose $n \leq 4$; by Claim 2.1, we have a comparison configuration $(\tilde{p}, \tilde{x}_1, \ldots, \tilde{x}_n)$ with center $p$.

We say that an array $(p, x_1, \ldots, x_n)$ is tense with center $p$ if the comparison configuration $(\tilde{p}, \tilde{x}_1, \ldots, \tilde{x}_n)$ is unique up to congruence and isometric to the original array.

Note that if $(p, x_1, \ldots, x_n)$ is tense, then in its comparison configuration $\tilde{p}$ lies in the convex hull of the remaining points $\tilde{x}_1, \ldots, \tilde{x}_n$. In particular,

\[(\star) \quad \sum_i \lambda_i \cdot (\tilde{x}_i - \tilde{p}) = 0\]

for some nonnegative coefficients $\lambda_1, \ldots, \lambda_n$ such that $\lambda_1 + \cdots + \lambda_n = 1$. If we can choose all positive $\lambda_i$ in $(\star)$, then we say that $(p, x_1, \ldots, x_n)$ is a nondegenerate tense array. The following statement describes nondegenerate tense arrays.

4.1. Claim. Assume $n \leq 4$ and $(p, x_1, \ldots, x_n)$ is an array of points with a metric that satisfies LSS($n$) with center $p$. Suppose we have equality in LSS($n$) for some positive $\lambda$-parameters; that is, for some positive values $\lambda_1, \ldots, \lambda_n$ we have

\[\sum_{i,j} a_{i,j} \lambda_i \lambda_j = 0,\]

where $a_{i,j} = |p - x_i|^2 + |p - x_j|^2 - |p - x_i - x_j|^2$. Then $(p, x_1, \ldots, x_n)$ is a nondegenerate tense array with center $p$.

Proof. By Claim 2.1, we have a comparison configuration $(\tilde{p}, \tilde{x}_1, \ldots, \tilde{x}_n)$ with center $p$. Set

\[\tilde{a}_{i,j} = \langle \tilde{x}_i - \tilde{p}, \tilde{x}_j - \tilde{p} \rangle = |\tilde{p} - \tilde{x}_i|^2 + |\tilde{p} - \tilde{x}_j|^2 - |\tilde{x}_i - \tilde{x}_j|^2.\]

Since $|\tilde{x}_i - \tilde{x}_j| \geq |x_i - x_j|$, we have $\tilde{a}_{i,j} \leq a_{i,j}$ for any $i$ and $j$. Note that

\[0 = \sum_{i,j} a_{i,j} \lambda_i \lambda_j \geq \sum_{i,j} \tilde{a}_{i,j} \lambda_i \lambda_j = 2 \left( \sum_i \lambda_i \cdot (\tilde{x}_i - \tilde{p}) \right)^2 \geq 0.\]
It follows that
\[ \sum_i \lambda_i (\bar{x}_i - \bar{p}) = 0. \]

Further, \( \bar{a}_{i,j} = a_{i,j} \), and, therefore, \( |\bar{x}_i - \bar{x}_j| = |x_i - x_j| \) for all \( i \) and \( j \) — hence the result.

Note that any 2-point array is a degenerate tense array; the center can be chosen arbitrarily. A 3-point array \( (p, x, y) \) is tense with center \( p \) if we have equality
\[ |p - x| + |p - y| = |x - y|. \]
Note that any tense 3-point array is nondegenerate. A 4-point array \( (p, x, y, z) \) is tense with center \( p \) if there is an isometric comparison configuration \( (\tilde{p}, \tilde{x}, \tilde{y}, \tilde{z}) \) with \( \tilde{p} \) lying in the solid triangle \( \tilde{x}\tilde{y}\tilde{z} \). Note that if \( \tilde{p} \) lies in the interior of the solid triangle or the triangle is degenerate, then the array \( (\tilde{p}, \tilde{x}, \tilde{y}, \tilde{z}) \) is nondegenerate. Otherwise, if \( \tilde{p} \) lies on a side, say \([\tilde{x}, \tilde{y}]\) and the triangle \([\tilde{x}\tilde{y}\tilde{z}]\) is nondegenerate, then \( (\tilde{p}, \tilde{x}, \tilde{y}, \tilde{z}) \) is degenerate. In the latter case the 3-point array \( (\tilde{p}, \tilde{x}, \tilde{y}) \) is tense and nondegenerate.

4.2. Claim. Let \( x = (x_1, \ldots, x_5) \) be a 5-point array in a metric space that satisfies all LSS(4)-inequalities. Suppose that \( x \) has \( k \) three-point tense arrays, and no tense arrays with four and five points. If \( k \leq 4 \) then there is a 2-dimensional subspace \( S \) of quadratic forms on \( \mathbb{R}^4 \) such that for any form \( U \in S \) that is sufficiently close to zero the array with associated form \( W_x + U \) satisfies all LSS(4)-inequalities.

Proof. Given a tense three-point subarray of \( x \), say \( (x_1, x_2, x_3) \), consider the metrics on \( x \) such that the three distances between \( x_1 \), \( x_2 \), and \( x_3 \) are proportional to the original distances and the remaining distances are arbitrary. This set defines a subspace of quadratic forms of codimension 2 in the 10-dimensional space of quadratic forms on \( \mathbb{R}^4 \). Since \( k \leq 4 \), taking the intersection of all such subspaces we get a subspace \( S \) of dimension at least 2.

It remains to show that \( S \) meets the claim — assume not. That is, for arbitrary small \( U \in S \) the metric on \( x \) defined by associated quadratic form \( W_x + U \) does not satisfy the LSS(4)-inequality. It means that there is a vector \( w \in K_5 \) such that
\[ W_x(w) + U(w) < 0. \]

Choose a positive quadratic form \( I \) and minimal \( t > 0 \) such that
\[ W_x(w) + U(w) + t \cdot I(w) \geq 0 \quad (***) \]
for any \( w \in K_5 \).

Note that for some \( w \in K_5 \), we have equality in (**). The metric on \( x \) that corresponds to the form \( W_x + U + t \cdot r \) satisfies all LSS(4) inequalities and by 4.1, it has a tense array with at least 3 points. However, since \( t > 0 \), it has no 3-point tense arrays.
Choose an array $Q$ that remains to be tense as $U \to 0$. Note that $Q$ is isometric to an array in the Euclidean space. Since $W_x + U + t \cdot I \to W_x$ as $U \to 0$, the array $Q$ must contain one of the three-point tense arrays for the original metric. That is, one of the three-point arrays sits in a four-point array that is isometric to an array in the Euclidean space. It follows that there is a degenerate 4-point array for the original metric — a contradiction.

\section{Extremal metrics}

Denote by $A_5$ the space of metrics on a 5-point set $F = \{a, b, c, d, e\}$ that admits an embedding into a Riemannian manifold with nonnegative curvature. The associated quadratic forms for spaces in $A_5$ form a convex cone in the space of all quadratic forms on $\mathbb{R}^4$. The latter follows since nonnegative curvature survives after rescaling and passing to a product space.

Denote by $B_5$ the space of metrics on $F$ that satisfies all Lang–Schroeder–Sturm inequalities for all relabelings. As well as for $A_5$, the associated forms for spaces in $B_5$ form a convex cone in the space of all quadratic forms on $\mathbb{R}^4$.

Since the associated quadratic form describes its metric completely, we may identify $A_5$ and $B_5$ with $\mathbb{R}^{10}$. This way we can think that $A_5$ and $B_5$ are convex cones in $\mathbb{R}^{10}$.

The set $B_5$ is a cone so it does not have extremal points except the origin. The origin corresponds to degenerate metric with all zero distances. But $B_5$ is a cone over a convex compact set $B'_5$ in the sphere $S^9 \subset \mathbb{R}^{10}$. The extremal points of $B'_5$ correspond to extremal rays of $B_5$; metrics on extremal rays will be called extremal. Note that if an extremal metric $\rho$ lies in the interior of a line segment between metrics $\rho'$ and $\rho''$ in $B_5$, then both metrics $\rho'$ and $\rho''$ are proportional to $\rho$.

Since Lang–Schroeder–Sturm inequalities are necessary for the existence of isometric embedding into nonnegatively curved Alexandrov space, we have that

$$A_5 \subset B_5.$$ 

To prove the theorem we need to show that the opposite inclusion holds as well. Since $B_5$ is the convex hull of its extremal metrics, it is sufficient to prove the following:

\begin{proposition}
Given an extremal space $F$ in $B_5$, there is a complete non-negatively curved Riemannian manifold that contains an isometric copy of $F$.
\end{proposition}

\begin{proof}
Note that any extremal space $F$ contains a tense set. If not, then an arbitrary slight change of metric keeps it in $B_5$; the latter is impossible for an extremal metric.

The remaining part of the proof is broken into cases:
- $F$ contains a 5-point tense set. In this case $F$ admits an isometric embedding into Euclidean space — the problem is solved.
- $F$ contains a 4-point tense set. This case follows from in Proposition 6.1 below.
\end{proof}
\( \diamond \) \( F \) contains only 3-point tense sets. This is the hardest part of the proof; it follows from in Proposition 7.1.

6 Four-point tense set

6.1. Proposition. Suppose that a 5-point metric space \( F \) satisfies all Lang–Schroeder–Sturm inequalities and contains a 4-point tense set. Then \( F \) is isometric to a subset of complete nonnegatively curved Riemannian manifold.

In the following proof, we first construct a nonnegatively curved Alexandrov space with an isometric copy of \( F \) and then smooth it. The space will be a doubling of a convex polyhedral set in \( \mathbb{R}^3 \).

Further we use notations

\[
[x_y], \quad \angle[x_y], \quad \text{and} \quad \tilde{\angle}(x_y)
\]

for hinge, its angle measure, and the model angle respectively.

**Proof.** Let us label the points in \( F \) by \( p, q, x_1, x_2, \) and \( x_3 \) so that the array \( (p, x_1, x_2, x_3) \) is tense with center \( p \).

By the definition of a tense array, we can choose an array \( (\tilde{p}, \tilde{x}_1, \tilde{x}_2, \tilde{x}_3) \) in \( \mathbb{R}^2 \) that is isometric to \( (p, x_1, x_2, x_3) \). Consider \( \mathbb{R}^2 \) as a plane in \( \mathbb{R}^3 \).

By 2.1, we can apply the \((4+1)\)-comparison. It implies the existence of point \( \tilde{q} \in \mathbb{R}^3 \) such that

\[(\ast) \quad |\tilde{p} - \tilde{q}|_{\mathbb{R}^3} = |p - q|_{F} \quad \text{and} \quad |\tilde{x}_i - \tilde{q}|_{\mathbb{R}^3} \geq |x_i - q|_{F}\]

for any \( i \).

Further, let us show that there are points \( \tilde{q}_1, \tilde{q}_2, \tilde{q}_3 \) in the plane thru \( \tilde{p}, \tilde{x}_1, \tilde{x}_2, \) and \( \tilde{x}_3 \) such that the following four conditions

\[(\ast\ast) \quad |\tilde{p} - \tilde{q}_i|_{\mathbb{R}^3} \geq |p - q|_{F}, \quad |\tilde{x}_j - \tilde{q}_i|_{\mathbb{R}^3} \geq |x_j - q|_{F}, \quad |\tilde{x}_i - \tilde{q}_i|_{\mathbb{R}^3} = |x_i - q|_{F}\]

hold for all \( i \) and \( j \).

Denote by \( \Gamma_1 \) the intersection of the circle with the angle vertical to the hinge \( [\tilde{x}_2 \tilde{x}_3] \). Let us show that \( \tilde{q}_1 \) can be chosen on \( \Gamma_1 \). The point \( \tilde{q}_1 \) has to satisfy additional three conditions:

\[
\angle[\tilde{x}_1 \tilde{x}_2 \tilde{q}_1] \geq \tilde{\angle}(x_1 x_2), \quad \angle[\tilde{x}_1 \tilde{x}_3 \tilde{q}_1] \geq \tilde{\angle}(x_1 x_3), \quad \angle[\tilde{x}_1 \tilde{q}_1 \tilde{q}_3] \geq \tilde{\angle}(x_1 q_3).
\]

Each condition describes a subarc of the of \( \Gamma_1 \), say \( \tilde{X}_{1,2}, \tilde{X}_{1,3}, \) and \( \tilde{P}_1 \).

By the construction and comparison we have

\[
\tilde{\angle}(x_1 x_2) + \tilde{\angle}(x_1 x_3) + \tilde{\angle}(x_1 x_2) \leq 2\pi, \\
\tilde{\angle}(x_1 q_1) + \tilde{\angle}(x_1 x_3) + \tilde{\angle}(x_1 p_1) \leq 2\pi, \\
\tilde{\angle}(x_1 x_2) = \angle[\tilde{x}_1 \tilde{x}_2], \quad \tilde{\angle}(x_1 x_3) = \angle[\tilde{x}_1 \tilde{x}_3], \quad \tilde{\angle}(x_1 q_1) = \angle[\tilde{x}_1 q_1].
\]
These inequalities and identities imply that each pair of arcs \( \tilde{X}_{1,2}, \tilde{X}_{1,3}, \) and \( \tilde{P}_1 \) have nonempty intersection. By 1-dimensional Helly’s theorem, all three arcs intersect; so we can choose \( \tilde{q}_1 \) in this intersection. The same way we construct \( \tilde{q}_2 \) and \( \tilde{q}_3 \).

Now let us show that there is a point \( \tilde{s} \in \mathbb{R}^2 \) such that

\[
|\tilde{p} - \tilde{s}|_{\mathbb{R}^3} \leq |p - q|_F, \quad |\tilde{x}_i - \tilde{s}|_{\mathbb{R}^3} \leq |x_i - q|_F.
\]

for all \( i \). In other words, the following four closed balls have a nonempty intersection: \( B[\tilde{p}, |p - q|_F] \) and \( B[\tilde{x}_i, |x_i - q|_F] \) for all \( i \). Indeed, by the overlap lemma [2], any 3 of these balls have a nonempty intersection; it remains to apply Helly’s theorem. Note that we can assume that \( \tilde{s} \) lies in the convex hull of \( \tilde{x}_1, \tilde{x}_2, \) and \( \tilde{x}_3 \).

The four perpendicular bisectors to \([\tilde{s}, \tilde{q}_1], [\tilde{s}, \tilde{q}_1], [\tilde{s}, \tilde{q}_2], [\tilde{s}, \tilde{q}_3] \) cut from \( \mathbb{R}^3 \) a closed convex set \( V \) that contains \( \tilde{s} \). (It might be a one-sided infinite triangular prism or, if \( \tilde{q} \) lies in the plane of the triangle, a two-sided infinite quadrangular prism.) Note that the inequalities (*) and (**) imply that \( V \) contains the points \( \tilde{p}, \tilde{x}_1, \tilde{x}_2, \tilde{x}_3 \).

Consider the doubling \( W \) of \( V \) with respect to its boundary; it is an Alexandrov space with nonnegative curvature [7, 5.2]. Denote by \( \iota_1 \) and \( \iota_2 \) the two isometric embeddings \( V \rightarrow W \). By construction, the array \( \tilde{p} = \iota_1(\tilde{p}), \tilde{x}_1 = \iota_1(\tilde{x}_1), \tilde{x}_2 = \iota_1(\tilde{x}_2), \tilde{x}_3 = \iota_1(\tilde{x}_3), \tilde{s} = \iota_2(\tilde{s}) \) in \( W \) is isometric to the array \( (p, q, x_1, x_2, x_3) \) in \( F \).

Finally, we need to show that the obtained space can be smoothed into a Riemannian manifold that still has an isometric copy of \( F \). This part is divided into two steps; first, we show that the construction above can be made so that the points \( \tilde{s}, \tilde{p}, \tilde{x}_1, \tilde{x}_2, \tilde{x}_3 \) do not lie on the edges \( V \). In this case, there is a complement, say \( U \), of a neighborhood of the singular set in \( W \) that contains the 5-point set together with all the geodesics between them. After that, we construct a smooth Riemannian manifold with nonnegative curvature that contains an isometric copy of \( U \).

**Step 1.** Consider the four ellipsoids \( P, X_1, X_2, X_3 \) with the major axes \(|q - p|, |q - x_1|, |q - x_2|, |q - x_3| \), first focus at \( \tilde{s} \), and the second focus at \( \tilde{p}, \tilde{x}_1, \tilde{x}_2, \tilde{x}_3 \) respectively.

The construction of the facets of \( V \) above implies that for each ellipsoid there is a tangent plane that contains all the ellipsoids on one side — these planes are the perpendicular bisectors to \([\tilde{s}, \tilde{q}], [\tilde{s}, \tilde{q}_1], [\tilde{s}, \tilde{q}_2] \) for all \( i \). Note that any choice of such planes do the trick — they can be used instead of perpendicular bisectors discussed above. These planes will be called \( p \)-plane and \( x_i \)-planes respectively. We need to choose them so that no pair of these planes pass thru \( \tilde{p}, \tilde{x}_1, \tilde{x}_2, \) or \( \tilde{x}_3 \). The latter is only possible if the corresponding ellipsoid degenerates to a line segment.

We can assume that one of the ellipsoids is nondegenerate; otherwise, the array \( \tilde{p}, \tilde{q}, \tilde{x}_1, \tilde{x}_2, \tilde{x}_3 \) is isometric to \( F \); in this case, \( F \) is isometric to a subset of
the Euclidean space. Further, if only one ellipsoid, say $X_1$ is degenerate, then we can move $\tilde{s}$ slightly making this ellipsoid nondegenerate and keeping the rest of its properties. So we can assume that three or two ellipsoids are degenerate.

Suppose $X_1$, $X_2$, $X_3$ are degenerate (picture on the left), then it is easy to choose $x_i$-planes tangent to $P$; it solves our problem. Another triple of ellipsoids, say $P$, $X_1$, $X_2$ might be degenerate only if $\tilde{p} \in [\tilde{x}_1, \tilde{x}_2]$. This case is even simpler — we can choose one plane that contains $\tilde{p}$, $\tilde{x}_1$, $\tilde{x}_2$, and tangent to $X_3$.

Now, suppose exactly two ellipsoids are degenerate, note that it cannot be $P$. Therefore we can assume that $X_1$ and $X_2$ are degenerate. In this case, we can assume that $\tilde{s} \in [\tilde{x}_1, \tilde{x}_2]$; if not we can slightly move $\tilde{s}$ toward to $\tilde{x}_1$ and $\tilde{x}_2$ making $X_1$ and $X_2$ nondegenerate and keeping the rest properties of $\tilde{s}$. Since a focus of $P$ lies on $[\tilde{x}_1, \tilde{x}_2]$, we have that $x_1$-plane cannot be $x_2$-plane and the other way around.

Suppose that $P$ does not lie in the convex hull of the remaining three ellipsoids and the same holds for $X_3$ (middle picture). Then it is easy to make the required choice of planes.

In the remaining case (see picture on the right), either $P$ or $X_3$ lies in the convex hull of the remaining three ellipsoids. Suppose it is $P$, draw a $p$-plane, note that it is also an $x_3$-plane; it might be also $x_1$- or $x_2$-plane, but cannot be both. It remains to add $x_1$-plane and/or $x_2$-plane as needed. Since $x_1$-plane cannot be $x_2$-plane and the other way around, we will not get two planes passing thru $x_1$ or $x_2$.

The case when $X_3$ lies in the convex hull of the rest is identical.

**Step 2.** Start with the subset $V' \subset V$ that lies on the distance $\pi \cdot \delta$ from its boundary. Think of $V'$ lying in $\mathbb{R}^4$, pass to its $2 \cdot \delta$-neighborhood. The boundary of the obtained neighborhood is a convex hypersurface $W'$ in $\mathbb{R}^4$. For small $\delta > 0$, it meets all the required conditions, except it is only $C^{1,1}$-smooth. It is straightforward to smooth $W'$ so that the metric changes only near the edges of $V$. In this case, the set $F$ remains isometrically embedded in the obtained 3-dimensional manifold. \qed

7 Three-point tense sets

7.1. **Proposition.** Suppose that an extremal 5-point metric space $F$ contains only 3-point tense sets. Then $F$ is isometric to a subset in a nonnegatively curved Riemannian manifold. Moreover, we can assume that $L$ is homeomorphic to a circle or the plane.
A three-point tense set \( \{a, b, c\} \) with center \( b \) will be briefly denoted by \( abc \). Observe that \( F \) has tense set \( abc \) if and only if
\[
|a - b|_F + |b - c|_F = |a - c|_F.
\]

On the diagrams, we will connect three-point tense sets by a smooth curve so that the center is in the middle. For example, the given diagram describes a metric on \( \{a, b, c, d, e\} \) with five tense sets \( abc, bcd, cda, dae, aec \).

The proof of the proposition relies on the following classification:

**7.2. Key lemma.** Let \( F \) be an extremal 5-point metric space; suppose that it has no tense subsets with 4 and 5 points. Then \( F \) has one of three configurations of tense sets shown on the diagram.

In other words, the points in \( F \) can be labeled by \( \{a, b, c, d, e\} \) so that it has one of the following three tense-set configurations:

- \( abc, bcd, cda, dae, aec \);
- \( abc, bcd, cda, dab, aec, bed \);
- \( abc, bcd, cda, dab, aec, bed \).

In the following proof we use only small part of the classification in Lemma 7.2. Namely, we use that if it is not the first case in the lemma, then there are two tense sets with shared center. However, the proof of this small part takes nearly as long as the complete classification.

**Proof of 7.1 modulo 7.2.** Suppose that \( F \) has a tense configuration as on the diagram. In other words, we can label points in \( F \) by \( \{x_1, x_2, x_3, x_4, x_5\} \) so that
\[
|x_i - x_{i-1}|_F + |x_{i+1} - x_i|_F = |x_{i+1} - x_{i-1}|_F
\]
for any \( i \) (mod 5). In this case, \( F \) is isometric to a 5-point subset in the circle of length \( \ell = |x_1 - x_2|_F + \cdots + |x_4 - x_5|_F + |x_5 - x_1|_F \).

By the key lemma, it remains to consider the case with two tense triples with a common center. Let us relabel \( F \) by \( x, v_1, v_2, w_1, w_2 \) so that \( F \) has tense triples \( v_1xv_2 \) and \( w_1wxw_2 \).

First, we construct an Alexandrov space \( L \) — a disc triangulated by four triangles with vertices \( \hat{x}, \hat{v}_1, \hat{v}_2, \hat{w}_1, \hat{w}_2 \) as shown on the diagram. Each of the four triangles has a flat metric with at most one singular point; in other words, each triangle is a solid geodesic triangle in a cone. The sides of the triangles are the same as in \( F \).

Note that the metric on the obtained disc is completely determined by the 12 angles of triangles. It remains to choose these angles in such a way that \( L \) has nonnegative curvature and the map \( \iota: F \to L \) defined by \( x \mapsto \hat{x}, v_1 \mapsto \hat{v}_1, w_1 \mapsto \hat{w}_1 \) is distance-preserving. By
construction, $\iota$ is distance-nonexpanding; therefore we only need to show that it is distance-noncontracting.

This part is divided into two steps.

**Step 1.** In this step, we describe three groups of conditions on these 12 angles and show that together they guarantee that $L$ has nonnegative curvature in the sense of Alexandrov and $\iota$ is distance-preserving.

First we need that the 12 angles of the triangles are at least as large as the corresponding model angles; that is,

\[(*) \quad \angle[\hat{x} \hat{v}_{i}] \geq \tilde{\zeta}(x_{w_{i}}), \quad \angle[\hat{v}_{i} \hat{z}] \geq \tilde{\zeta}(v_{i} x_{w_{i}}), \quad \angle[\hat{w}_{j} \hat{z}] \geq \tilde{\zeta}(w_{j} x_{w_{i}}),\]

for all $i$ and $j$. Note that this condition implies that each edge of the triangulation is a convex set in $L$. In particular, it implies that $\iota$ preserves the distances between all pairs $(x, v_{i})$, $(x, w_{j})$, and $(v_{i}, w_{j})$ for all $i$ and $j$. Moreover, it implies that any minimizing geodesic in $L$ may cross an edge $xv_{i}$ or $xw_{j}$ at most once.

Further, choose a three-edge path in the triangulation connecting $v_{1}$ to $v_{2}$ (or $w_{1}$ to $w_{2}$), say $v_{1}w_{1}xv_{2}$. Consider the polygonal line in the plane $\hat{v}_{1}\hat{w}_{1}\hat{x}\hat{v}_{2}$ with the same angles and sides as in $L$ such that $\hat{v}_{1}$ and $\hat{v}_{2}$ lie on the opposite sides from the line $\hat{w}_{1}\hat{x}$. Set

\[\tilde{\zeta}(v_{1}w_{1}xv_{2}) := |\hat{v}_{1} - \hat{v}_{2}|.\]

The next group of conditions has eight comparisons:

\[(***) \quad |v_{1} - v_{2}| \leq \tilde{\zeta}(v_{1}w_{1}xv_{2}), \quad |v_{1} - v_{2}| \leq \tilde{\zeta}(v_{1}w_{1}xv_{2}), \quad |w_{1} - w_{2}| \leq \tilde{\zeta}(w_{1}v_{1}w_{2}), \quad |w_{1} - w_{2}| \leq \tilde{\zeta}(w_{1}v_{1}w_{2}).\]

for any $i$. These conditions imply that $\iota$ preserves the distance between two remaining pairs $(v_{1}, v_{2})$ and $(w_{1}, w_{2})$. Indeed, suppose that a minimizing geodesic $\gamma$ from $\hat{v}_{1}$ to $\hat{v}_{2}$ is shorter than $|v_{1} - v_{2}|_{\mathcal{F}}$. Since two edges $\hat{v}_{1}\hat{x}$ and $\hat{x}\hat{v}_{2}$ have total length $|v_{1} - v_{2}|_{\mathcal{F}}$, we can assume that $\gamma$ runs in a pair of two adjacent triangles, say $[\hat{v}_{1}\hat{x}\hat{w}_{1}]$ and $[\hat{v}_{2}\hat{x}\hat{w}_{1}]$. From above $\gamma$ cross the edge $\hat{x}\hat{w}_{1}$ once. Denote by $\hat{z}_{1}$ and $\hat{z}_{2}$ the singular points in the triangles $[\hat{v}_{1}\hat{x}\hat{w}_{1}]$ and $[\hat{v}_{2}\hat{x}\hat{w}_{1}]$. We have the following 4 options:

Both points $z_{1}$ and $z_{2}$ lie on the left side from $\gamma$. In this case, the statement follows from two inequalities in $(*)$; namely

\[\angle[\hat{x} \hat{v}_{i}] \geq \tilde{\zeta}(x_{w_{i}})\]

for both choices of $i$. 

\[11\]
Both points \( z_1 \) and \( z_2 \) lie on the right side from \( \gamma \). In this case, the statement follows from two inequalities in (\(*\)) \text{namely}

\[
\angle[\hat{w}_1 \hat{v}_i] \geq \tilde{\angle}(w_1 v_i)
\]

for both choices of \( i \).

Points \( z_1 \) lies on the left side from \( \gamma \), and \( z_2 \) lies on its right side. In this case, the statement follows from an inequality in (\(*\ast\)); namely

\[
|v_1 - v_2| \leq \tilde{Z}(v_1 x w_1 v_2).
\]

Points \( z_1 \) lies on the right side from \( \gamma \), and \( z_2 \) lies on its left side. In this case, the statement follows from an inequality in (\(*\ast\)); namely

\[
|v_1 - v_2| \leq \tilde{Z}(v_1 w_1 x v_2).
\]

We need one more group of conditions:

\[
(\ast\ast) \quad \angle[\hat{v}_i \hat{\hat{v}}_1] + \angle[\hat{v}_i \hat{\hat{v}}_2] \leq \pi, \quad \angle[\hat{w}_i \hat{\hat{v}}_1] + \angle[\hat{w}_i \hat{\hat{v}}_2] \leq \pi.
\]

for any \( i \). These inequalities in (\(*\ast\)) imply that \( L \) has a convex boundary, and therefore, it is an Alexandrov space with nonnegative curvature.

\textit{Step 2.} In this step we show that the 12 angles can be chosen so that they meet all the conditions (\(*\)), (\(*\ast\)), and (\(*\ast\ast\)). This part is done by means of elementary geometry.

By 2.1, we can apply \((4+1)\) comparison for the array \( x, v_1, v_2, w_1, w_2 \). This way we get points \( \hat{x}, \hat{v}_1, \hat{v}_2, \hat{w}_1, \hat{w}_2 \) such that

\[
|\hat{x} - \hat{v}_1|_{H} = |x - v_1|_{A}, \quad |\hat{x} - \hat{w}_1|_{H} = |x - w_1|_{A}, \quad |\hat{v}_1 - \hat{w}_2|_{H} \geq |v_1 - w_2|_{A}, \quad |\hat{w}_1 - \hat{w}_2|_{H} \geq |w_1 - w_2|_{A}.
\]

The triangle inequality together with the conditions described by the diagram implies equality in the last two inequalities; that is, each of points \((\hat{v}_1, \hat{x}, \hat{v}_2)\) and \((\hat{w}_1, \hat{x}, \hat{w}_2)\) lies on one line. In particular, the whole configuration lies in \( \mathbb{R}^2 \).

Set

\[
\angle[\hat{x} \hat{v}_i] = \angle[\hat{x} \hat{v}_j]
\]

for all \( i \) and \( j \). Evidently, this choice meets four conditions in (\(*\)).
We still need to choose the remaining 8 angles \( \angle \widehat{v}_i \widehat{w}_j \) and \( \angle \widehat{w}_j \widehat{v}_i \) for all \( i \) and \( j \). To do this we will extend the configuration \( \hat{x}, \hat{v}_1, \hat{v}_2, \hat{w}_1, \hat{w}_2 \) by 8 more points \( \hat{v}_{ij}, \hat{w}_{ij} \) so that we can set

\[
\angle \widehat{v}_i \widehat{w}_j = \angle \widehat{v}_i \widehat{v}_{ij}, \quad \angle \widehat{w}_j \widehat{v}_i = \angle \widehat{w}_j \widehat{w}_{ij}.
\]

We assume that \( |\hat{v}_i - \hat{w}_{ij}| = |v_i - w_j| \) and \( |\hat{w}_j - \hat{v}_{ij}| = |w_i - v_j| \) for all \( i \) and \( j \). The conditions (*) and (**) will follow if we could choose the points so that

\[
|\hat{x} - \hat{v}_{ij}| \geq |x - v_j|, \quad |\hat{x} - \hat{v}_{ij}| \geq |x - w_j|,
\]

\[
|\hat{v}'_{ij} - \hat{v}_{ij}| \geq |v'_j - v_j|, \quad |\hat{w}'_{ij} - \hat{w}_{ij}| \geq |w'_j - w_j|,
\]

here we assume that \( j' \neq j \), so \( 2' = 1 \) and \( 1' = 2 \).

The needed points \( \hat{w}_{21} \) and \( \hat{w}_{22} \) can be chosen to be reflections of \( \hat{w}_1 \) and \( \hat{w}_2 \) respectively across a line \( \ell \) that we are about to describe. Suppose \( \triangle \hat{v}_1 \hat{w}_1 \hat{w}_2 \) is a model triangle for \( \triangle v_2 w_1 w_2 \) such that \( \hat{s} \) lies on the opposite side from \( \hat{v}_2 \) with respect to the line \( \hat{v}_1 \hat{w}_2 \). Then \( \ell \) is the perpendicular bisector of \( [\hat{v}_1, \hat{s}] \). Since \( |\hat{w}_1 - \hat{v}_1| \geq |w_1 - v_1| = |\hat{w}_1 - \hat{s}| \) the points \( \hat{w}_1 \) and \( \hat{w}_2 \) lie on the opposite side from \( \hat{v}_1 \) with respect to \( \ell \). Whence the conditions on \( \hat{w}_{21} \) and \( \hat{w}_{22} \) follow. In addition, by construction, we get \( (s^*_k) \) at \( \hat{v}_2 \).

Similarly, we construct the remaining 6 points.

**Final step.** It remains to modify \( L \) into a plane with a smooth Riemannian metric. First, note that \( L \) is a convex subset of a flat plane with at most 4 conic points. Further, the geodesics between the 5-point subset in \( L \) do not visit these conic points. Therefore a slight smoothing around singularities does not create a problem.

**Proof of 7.2.** Since \( F \) is extreme, any pair of points of \( F \) must lie in a tense set. If not, then all \( LSS(4) \) inequalities will remain to hold after a slight change of the distance between the pair. The latter contradicts that \( F \) is extreme.

Suppose that two tense triples share two points. All possible 4 configurations are shown on the diagram; they will be referred as \( C, O, P, \) and \( Y \) respectively. Observe that in the configurations \( P \) and \( Y \), the set \( \{a, b, c, d\} \) with center \( b \) must be tense. Indeed, in the \( P \)-case the 4-point space is isometric to a 4-point subset on a line with order \( a, d, b, c \). In the \( Y \)-case, \( \hat{L}(b^a_c) = \hat{L}(b^d_c) = \pi \), and the comparison implies that \( \hat{L}(b^a_d) = 0 \). Without loss of generality we may assume \( |a - b| \geq |d - b| \); in this case, the 4-point space is also isometric to a 4-point subset on a line with order \( a, d, b, c \). That is, if \( P \) or \( Y \) appear in \( F \), then \( F \) has a 4-point tense
The latter contradicts the assumptions; so $P$ and $Y$ cannot appear in our configuration.

Let us show that $F$ contains at least 5 tense triples; assume $F$ has at most 4 of them. By 4.2, the space of quadratic forms on $\mathbb{R}^4$ contains a subspace $S$ of dimension at least 2 such that for any form $U \in S$ for all $t$ sufficiently close to zero, the forms $W + tU$ satisfy all LSS(4). Therefore $F$ is not extremal — a contradiction.

The remaining part of the proof is a brute force search of all possible configurations that satisfy the conditions above. This search is sketched on the following diagram that needs some explanation. We start with a configuration with one triple marked by a solid line. Chose a pair that is not in any triple of configuration; connect it by a dashed line and search for an extra triple with this pair inside. Each time we need to check up to 9 triples that contain the pair — 3 choices for extra points and 3 choices for the center in the obtained triple. Some of them make a $P$ or $Y$ configuration with an existing triple, so they cannot be added. If some of them can be added, then we draw a new diagram connected by an arrow and continue. In many cases, symmetry might be used to reduce the number of cases.

If there are no free pairs (these are 12, 13, 15, and 16), then we need to check all triples, but due to symmetry, the number of triples can be reduced.

Once we did the classification, we need to find all configurations with at least 5 triples (these start with column 5) such that each pair belongs to one of the tense triples (those that have no dashed line). So we are left with three cases 13, 15, and 16 marked in bold; it proves the lemma.

The following table describes procedures at each node on the diagram. It uses the following notations. If a candidate triple, say $abd$, violates $Y$ rule with an existing triple, say $abc$, then we write $abdYabc$. Similarly, if a candidate triple,
say $adb$ violates $P$ rule with an existing triple, say $abc$, then we write $\bar{adb}Pabc$. Further, assume a candidate, say $dbe$, does not violate the rules and so it can be added. Suppose that after adding this triple we get a new configuration, say 4; in this case, we write $dbe\rightarrow 4$. Note that the new configuration is relabeled arbitrarily.

In cases 12, 13, 15, and 16 we check all triples up to symmetry. The used symmetries are marked in the third column.

8 Final remarks

Our theorem provides an affirmative answer to Question 6.2 in [5]. For 6-point metric spaces a direct analog of the theorem does not hold, but Question 6.3 in [5] might be an appropriate analog.

An analogous problem for 5-point sets in nonpositively curved spaces was solved by Tetsu Toyoda [10]; another solution is given in [5]. The 6-point case is open; Question 6.1 in [5] might be an answer.

The 4-point case is much easier; the classification as in 7.2 gives only two cases on the diagram. Both admit an embedding into a circle. It can be used to prove the following statement.

8.1. Theorem. Any 4-point space satisfying the nonnegative-curvature comparison admits an embedding into a product of a circle and the Euclidean space.

The following statement can be proved in a similar manner.

8.2. Theorem. Any 4-point space satisfying the nonpositive-curvature comparison admits an embedding into a product of a tripod and the Euclidean space.

These two results are analogous to Wald’s theorem mentioned above; they were obtained in an unpublished note by Vladimir Zolotov and the first author.

Most of our arguments can be applied to arbitrary curvature bound; Section 5 is the only place where we essentially use that the bound is zero.

It would be interesting to classify 5-point subsets in other classes of spaces; for example, in products of circles, or complete flat manifolds. It is not hard to see that the second and third types of spaces in 7.2 do not admit an embedding into a product of circles, so the answer must be different. We are not aware of 5-point spaces that admit an isometric embedding into a complete nonnegatively curved Riemannian manifold, but not in a flat manifold. Analogous questions can be asked about products of trees and Euclidean buildings; these are especially nice classes of spaces with nonpositive curvature.

Our argument can be applied to attack the 6-point case [5, Question 6.3], except we could no longer use LSS(5). The case of extremal metrics only with 3-point tense sets seems to be easier. The 5-point tense set can be solved following our argument in 6.1. At the moment we do not see a way to do the 6- and 4-point tense sets.
It might be interesting to find conditions on finite subsets of metric spaces that are related to other curvature bounds as, for example, nonnegative curvature operator or nonnegative isotropic curvature; see [3, 1.19+(e)].
