From Molecular Pathology of COVID-19 to *Nigella Sativum* as a Treatment Option: Scientific Based Evidence of Its Myth or Reality

Muhammad Atif¹, Farrah Naz², Junaid Akhtar³, Muhammad Imran⁴, Sidrah Saleem⁵, Javed Akram⁶, Muhammad Imran⁶, and Muhammad Ikram Ullah⁷

**ABSTRACT** COVID-19 virus is a causative agent of viral pandemic in human beings which specifically targets respiratory system of humans and causes viral pneumonia. This unusual viral pneumonia is rapidly spreading to all parts of the world, currently affecting about 105 million people with 2.3 million deaths. Current review described history, genomic characteristics, replication, and pathogenesis of COVID-19 with special emphasis on *Nigella sativum* (N. sativum) as a treatment option. *N. sativum* seeds are historically and religiously used over the centuries, both for prevention and treatment of different diseases. This review summarizes the potential role of *N. sativum* seeds against COVID-19 infection at levels of *in silico*, cell lines and animal models.

**KEYWORDS** coronavirus, nCoV-19, COVID-19, *Nigella sativum*, review

Coronaviruses (CoVs) belong to the Nidovirales order of Coronaviridae family which causes numerous illnesses of respiratory tract and respiratory syndromes.¹ CoVs mainly target humans and wild animals such as birds and mammals.² Four major subgroups of CoVs have been identified as: α -CoVs, β -CoVs, γ -CoVs and δ -CoVs with 17 subtypes.³ A novel coronavirus (2019-nCoV) which is 70% identical to severe acute respiratory syndrome coronavirus (SARS-CoV) was for the first time reported in December 2019 from Wuhan, China.⁴ This unusual viral infection quickly spread to all parts of the world with more than 105 million cases and about 2.3 million deaths globally so far.⁵ This virus was first isolated on 7th January, 2020 from a throat swab of COVID-19 patient by Chinese Center for Disease Control and Prevention (CDC). The virus was eventually named as 2019-nCoV by World Health Organization (WHO).⁶ Initially, a typical COVID-19 patient shows pneumonia-like symptoms, which later on aggravate to many respiratory illnesses like acute respiratory failure and acute respiratory distress syndrome (ARDS).⁷⁸

**Genome (Strains and Evolutionary Capability)**

Viruses belonging to Coronaviridae family are positive sense, single stranded RNA viruses.⁸ A coronavirus is a pleomorphic, spherical, and enveloped particle. The virus contains a matrix protein and its RNA is coupled with a nucleoprotein inside a capsid. There are club-shaped projections of glycoproteins on its envelope. The genome of coronavirus encodes 4 structural proteins; envelope (E), membrane (M2), nucleocapsid (N) and spike (S) proteins.¹ The COVID-19 virus attaches to the host surface receptors by its receptor-binding domain (RBD), present on the S protein, which is involved in fusion of the host and viral cell membranes to permit the viral entry into the host cell.⁹ The S-protein of coronavirus contains multiple epitopes for its binding to the host cell. Thus the neutralization of S protein, can make it an ideal candidate for vaccine design.¹⁰

Recent phylogenetic analyses of CoVs have shown that COVID-19 is phylogenetically similar to Bat CoV (BCov) and SARS-CoV.¹¹ SARS-CoV and COVID-19 genomes share an average sequence similarity of 79% with their S protein is 76.47% similar.¹²

The full-length genome sequencing of COVID-19 virus showed that it is divergent form MERS-CoV and SARS-CoV which caused past epidemics and it belongs to β-CoVs.\(^{(12)}\)

The phylogenetic analyses of various coronavirus lineages have shown variable number of small open reading frames (ORFs) among different conserved regions of the genome and at the downstream to nucleocapsid gene. The S gene of coronavirus possesses a unique N-terminal fragment. The genome of all coronaviruses has shown that the important structural genes exist in the direction of 5'-3' at the order of S, E, M, and N. Hemagglutinin-esterase (HE) protein such as 3a/b and 4a/b proteins are also present in some coronaviruses which play essential role in virus replication and genome repairs.\(^{(13)}\)

### Pathogenesis

Patients diagnosed with COVID-19 present abnormal respiratory findings, elevated levels of plasma pro-inflammatory cytokines and leukocyte count.\(^{(14)}\) COVID-19 targets the respiratory system causing viremia, severe pneumonia, along with the manifestation of ground-glass opacities, and severe cardiac injury.\(^{(4)}\) The increased secretions of chemokines and pro-inflammatory cytokines leads to cytokine storm and include fibroblast growth factor 2 (FGF2), granulocyte colony-stimulating factor (GCSF), granulocyte-macrophage colony-stimulating factor (GMCSF), interferon gamma (IFN\(\gamma\)), interferon gamma-induced protein 10 (IP10), monocyte chemotactant protein-1 (MCP1), macrophage inflammatory proteins alpha (MIP1\(\alpha\)), macrophage inflammatory proteins beta (MIP1\(\beta\)), platelet derived growth factor subunit B (PDGFB), tumor necrosis factor-alpha (TNF\(\alpha\)), vascular endothelial growth factor A (VEGFA), interleukin 1 (IL-1) beta (IL1-\(\beta\)), IL receptor antagonist (IL1RA), IL-7, IL-8, and IL-9.\(^{(4)}\)

COVID-19 virus enters and infects the host cell by the attachment of its S protein with the host cell surface receptor known as angiotensin converting enzyme 2 (ACE\(\text{2}\)). To completely enter the host cell, the S protein must be primed with a host protease enzyme named as transmembrane protease, serine 2 (TMPRSS2).\(^{(15,16)}\) (Figure 1).

After the entrance of COVID-19 virus into the host cell, uncoating of the virus occurs. The transcription and translation of the virus occurs at the host cytoplasmic membranes. This step requires coordination between continuous and discontinuous RNA synthesis which is regulated by a large complex viral replicate protein. This complex viral replicate protein is encoded by replicate gene of about 20-kb size and contain 16 viral subunits along with many cellular proteins.\(^{(17)}\) Most of the RNA viruses contain RNA helicase, RNA dependent RNA polymerase (RdRp), and protease activities. However, COVID-19 virus replicate has been found to use several RNA processing enzymes that are not present or exceedingly rare in other RNA viruses. These enzymes include putative sequence specific endoribonuclease, ADP ribose 10-phosphatase and 30–50 exoribonuclease, 20-O-ribosemethyltransferase and group 2 coronaviruses cyclic phosphodiesterase.\(^{(18)}\) After synthesis, assembly of proteins takes place at the cell membrane and there occurs insertion of the genomic RNA into viral coat to make a mature virion particle which is released by budding from the internal cell membranes.\(^{(19)}\)

### Factors Affecting COVID-19 Viral Pathogenesis

Cerebrovascular, cardiovascular and diabetes are the most common co-morbidities associated with COVID-19 infection. Many other disorders such as myocardial injury, kidney and hepatic injury, coagulation activation, cellular immunodeficiency, and secondary bacterial infections in COVID-19 patients are also noted.\(^{(20)}\) Chronic inflammation and lymphopenia have also been reported in most instances of serious illness. In fact, these findings of COVID-19 patients are closer to the findings observed in patients having SARS and demonstrate a probable common biological process behind these epidemiological disorders.\(^{(21)}\)

### Vaccines and Therapeutic Approaches against COVID-19 Infection

Many types of vaccines and antiviral drugs using S
protein of coronavirus have been tested. Du, et al\(^{(22)}\) revealed that vaccines can be made using full-length S protein, DNA, viral vector, recombinant RBD protein and recombinant S protein. The only partial success in treatment of COVID-19 infection has been achieved by some recombinant compounds like interferon in combination with ribavirin.\(^{(20)}\) It is noteworthy that receptor-binding domain of SARS-CoV has lower affinity for ACE\(_2\), while the receptor-binding domain of COVID-19 has a higher affinity for ACE\(_2\).\(^{(23)}\) Depending on this information, Gurwitz\(^{(26)}\) proposed the use of angiotensin receptor 1 (AT1R) blockers like losartan as a therapeutic approach against COVID-19 infection.

Currently, the treatment of choice against COVID-19 infection is monoclonal antibodies along with a novel adenosine analogue produg, remdesivir which was effectively used against Ebola infection in the past.\(^{(21,25)}\) Any adaptations in the sequence of the SARS-COV-2 may improve its transmission leading to its high virulence, however, SARS-COV-2 is predicted to become less virulent after human to human transmissions as genetic bottlenecks of RNA viruses usually occur by respiratory droplet transmissions.\(^{(26,27)}\)

**Herbal Treatment against COVID-19 Infection**

The outcomes of COVID-19 infection are mainly dependent on the immune status of the infected subjects, thus any herbal treatment possessing immune-modulatory functions may potentially prevent or cure the disease.\(^{(28,29)}\) The recent studies from China have demonstrated that the treatment efficacy of Chinese medicine (CM) was more than 90%, and only few COVID-19 subjects were admitted to intensive care unit (ICU). People from China are effectively using a collection of CM for thousands of years to treat various types of respiratory distress illnesses (RDI).\(^{(31,32)}\) Recently it has been shown that Keguan-1-based integrative therapy was safer and more effective than the standard treatment in supressing the development of ARDS in COVID-19 patients.\(^{(33)}\)

**Nigella sativum against COVID-19 Infection**

Recently the synergistic effect of N. Sativum (NS) and honey against COVID-19 infection was under clinical trial in Pakistan from April 30 to July 29, 2020.\(^{(34)}\) The study recruited 313 patients; 210 were moderate and 103 were severe syndrome patients. In both categories, almost half of the patients were administered honey and Nigella sativa (HNS), while the remaining half were administered placebos. The results showed that the time taken to alleviate COVID-19 symptoms was almost 50% reduced by HNS treatment. Moreover, HNS treatment also cleared the virus 4 days earlier than the placebos. The mortality rate in severe cases was 4 times less in HNS-treated group than the placebos. Additionally, there was no side effect of HNS treatment.\(^{(34)}\)

NS is the member of the Ranunculaceae (buttercup) family which has been widely studied and recognized worldwide.\(^{(35)}\) NS is a native plant in Southern Europe, Northern and Asia Minor. It is extensively cultivated in India and Pakistan.\(^{(36,38)}\) Despite its significant cultivation in Eastern Europe and North America, best grown seed are produced in Egypt.\(^{(36)}\) It is known as Habbatus Sauda, Allahabhat Alsawada and Alkamoun Alaswad in Islamic society and shuniz, kodera, black cumin or dark caraway in different part of the world.\(^{(40)}\)

It has been reported by numerous researchers that NS seeds possess many remedial properties such as immunopotentiation, bronchodilation, antitumor, antihistaminic, anti diabetic and antihypertensive effect. Researchers also support its anti-inflammatory properties, antibacterial, hepatoprotective, and gastroprotective properties. These medicinal effects are attributed to its quinone constituents.\(^{(41-44)}\)

**Bioactive Constituents of NS**

So far, several dynamic compounds are recognized from different types of NS seeds,\(^{(45)}\) which contain 24.76%–40.35% of fixed oil, 0.5%–1.5% volatile oil, quinones, alkaloids, saponins, and many additional compounds in less amounts.\(^{(41)}\) The essential oil has property of yellow to dark amber liquid and possess no fluorescence, even when diluted with alcohol.\(^{(46)}\)

Fatty acids, more specifically, unsaturated fatty acids are the major component of NS seeds. 50%–60% of fatty acids are linoleic acid, 20% are oleic acid, 10% are dihomo linoleic acid, while remaining 3% are eicodadienoic acid. The saturated fatty acids such as palmitic acid and stearic acid are also present but only in lesser amount, 30% or less.\(^{(38)}\) Furthermore, isochinoline alkaloids are present in the form of nigellimin and nigellimin-N-oxide, while pyrazol alkaloids are present in the form of nigellicin and nigelicin. Overall, NS seeds contain 29% fat followed by protein (27%), carbohydrates (25%), crude fiber (8%) and total ash (5%). NS seeds also have a little quantity of many vitamins and minerals such as copper, phosphorus, zinc, and iron.\(^{(40,46)}\)

It is shown by the literature that commercial NS oil is the
most important ingredient of all NS plants. The oil effect of NS is mainly due to quinone component, especially the essential oil quinone containing thymoquinone (TQ), which is an important bioactive substance that accounts for 30%–48% of all compounds. In one study, concentrations of Iranian-derived NS essential oil contained 13.7% thymoquinone while Indian-derived essential oil contained up to 50% thymoquinone. Storing essential oil when exposed to sunlight can cause chemical degradation of thymoquinone and high oligocondensation products. Therefore, due to mild photo-isomerization of thymoquinone, the essential oil needs to be protected from sunlight. Otherwise, it will lead to the accumulation of dithioquinone which is a thymoquinone dimer.

In silico Studies of NS Compounds against COVID-19

A recent study from Bouchentouf and Missoum demonstrated the potential role of NS biochemical components against COVID-19 infection. The technique of molecular docking was used to detect novel possible inhibitors from NS against COVID-19 virus.

Docking Score of NS Compounds and Other Clinical Trial Phase Drugs

Currently, different supportive treatment options for COVID-19 are available. Mostly, these treatment regimens are comprised of chloroquine, hydroxychloroquine, azithromycin, arbidol, remdesivir and favipiravir. The best obtained docking score among the drugs under clinical trial was for arbidol, when complexed with 6LU7. The docking score of remdesivir followed by chloroquine, hydroxychloroquine and azythromycin. The highest energy was provided by favipiravir when complexed with 6LU7. The best obtained docking score among the drugs under clinical test was for remdesivir, when complexed with 2GTB. After attaining the results, it was observed that nigellidine from NS seeds provides the lower energy when complexed with 6LU7, that is preeminent score when matched to other docked complexes. Nigellidine's score is also close to the energy score of chloroquine and better than hydroxychloroquine and favipiravir. When α-hederin was complexed with 2GTB active site, the energy score was better than chloroquine, hydroxychloroquine and favipiravir. All other compounds of NS (nigellicine, nigellimine, carvacrol, 6-thymol, thymoquinone, dithymoquinone and thymohydroquinone) included in the study gives energy score related to favipiravir.

Favipiravir is an antiviral drug which target RdRP and it is currently approved drug against influenza infection in Japan with half maximal inhibitory concentration (IC50) of 0.013–0.48 μg/mL. Chen, et al reported that favipiravir significantly improved the latency to relief for pyrexia and cough. Du, et al summarized 8 clinical trials and concluded that favipiravir provides a substitute for compassionate use in COVID-19 infection.

Interaction of NS Compounds with 6LU7

The interactions and 2D diagrams of other NS compounds with 6LU7 and 2GTB were also demonstrated. Maximum 3 hydrogen interactions with amino acids of 6LU7 were observed by NS compounds; α-hederin, carvacrol followed by 2 hydrogen interactions of NS compound, nigellicine. Only 1 hydrogen interactions with amino acids of 6LU7 were observed by NS compounds, including thymol, thymoquinone, dithymoquinone and thymohydroquinone, and no interaction in the case of nigellimine.

Interaction of NS Compounds with 2GTB

The interactions between compounds from NS with 2GTB showed that only nigellicine has maximum 3 hydrogen interactions with amino acids of 2GTB. Only one hydrogen interaction was observed in case of nigellidine, nigellimine and thymohydroquinone. The NS compounds with no interactions with 2GTB were carvacrol, thymol, thymoquinone and dithymoquinone.

Effects of NS on Coronavirus Cell Lines

It has been shown that NS extract can reduce the growth of coronavirus in the infected cell line epithelial carcinoembryonic anti-gen-related cell adhesion molecule 1.
The NS extract increases IL-8 secretion. IL-8 is possibly involved in priming of dendritic cells (DCs) with T cells during coronavirus infection and stimulation of calcium signaling which may further be associated with the transient receptor potential proteins (TRPs).\(^{(79)}\) TRP genes are involved in multiple cellular functions including regulation of intracellular Ca\(^{2+}\) ions.\(^{(71)}\)

There are 7 sub-families of TRP genes including TRPV (vanilloid), TRPM (melastatin), TRPC (canonical), TRPN and TRPA (ankyrin), TRPML (mucolipin) and TRPP (polycystin).\(^{(72)}\) There are several stimuli for triggering TRP channels such as, different growth factors, depletion of intracellular calcium level, different chemicals and temperatures. etc. The triggering pattern and selection of TRPs channels can also be dependent on stimulus.\(^{(72)}\)

It has been shown that the levels of TRPM6, TRPM7, TRPA1, TRPC4 are downregulated by NS extract.\(^{(69)}\) The increased intracellular Ca\(^{2+}\) ions are involved in enhanced viral replication. It is demonstrated that intracellular calcium signaling leads to enhanced production of reactive oxygen species in mitochondria which effect replication of influenza virus.\(^{(74)}\) It is also noted that poliovirus infection increases intracellular calcium concentration.\(^{(76)}\) Thus, increased intracellular calcium concentration might play crucial role in viral replication. On the contrary, viruses might target those cellular mechanisms which regulate intracellular calcium ion concentration. It was noted that NS extract significantly decreased coronavirus load in HeLa-CEACAM1a cell line. It was observed that after NS extract treatment and 6 h post infections, the number of viruses was very low and it was 1/10th as compared to the control amount at 8 h post infection.\(^{(69)}\)

**NS Mechanism of Action against COVID-19 Infection**  
**NS on Mast Cells and Inflammatory Mediators**

One of the most important immune cells that are activated during the pathogenesis of SARS-COV-2 virus are the mast cells (Appendix 1A). The mast cells have important role in inflammation and allergy. Once activated, secretion of histamine and proteases occur. The late mast cell activation leads to the secretion of pro-inflammatory cytokines (IL-1, IL-6, and TNF-\( \alpha \)).\(^{(76)}\) It is observed in COVID-19 subjects that there is systematic elevation of pro-inflammatory cytokines leading to the condition known as "cytokine storm" occurring more specifically in the lungs.\(^{(77)}\) The condition may further lead to sepsis with fatal organ damage.\(^{(76)}\) Thus the mast cell stabilizers such as ketotifen are most likely to possess antiviral activities.\(^{(79)}\) It has been observed in mice model of viral-induced sepsis that all mice treated with ketotifen and antiviral survived as compared to the untreated mice. Moreover, it was observed that virus induced lung lesions were also suppressed by ketotifen.\(^{(69)}\) Human studies of rheumatoid arthritis subjects have shown that the serum level of an anti-inflammatory cytokine like IL-10 was significantly increased when oil capsules of NS were administered.\(^{(81)}\) Furthermore, it has been observed that two enzymes in human blood cells i.e. 5-lipoxygenase and leukotriene C4 synthase, which can produce inflammatory mediators like leukotrienes and prostaglandins are also suppressed by NS oil and thymoquinone (Appendix 1A).\(^{(82,83)}\)

The anti-inflammatory and anti-histamine activities of different bioactive components of NS is well established in various animals models.\(^{(84,85)}\)

**NS on Autophagy**

The coronavirus infection leads to activation of unfolded protein response (UPR) as the virus replication require excessive protein biosynthesis to provide the sources for viral proteins and use of endoplasmic membrane for formation of double membrane vesicles (DMVs).\(^{(86)}\) The autophagy and UPR are interconnected, activation of UPRs may lead to the induction of autophagy.\(^{(87,88)}\) Therefore, it is suggested that COVID-19 infection may promote autophagy via activation of UPR in cells (Appendix 1B).

Presently most of the potential drug candidates (58%) against COVID-19 infection are autophagy modulators. It is interesting that all these modulators do not seem to directly antagonize the effects of coronavirus infection. The beneficial effects of these drugs are likely due to over accumulation of autophagosomes which leads to apoptotic cell death of virally infected cells and disrupt the viral replication cycle.\(^{(89)}\) It is highly recommended that pharmacological agents which stimulate autophagy may have potentially antiviral effects, more specifically against coronaviruses.\(^{(90)}\) A study has shown that one of NS compounds, thymoquinine acts as a cardioprotective agent by promoting autophagy in cardiac patients.\(^{(91)}\)

**NS on Oxidative Stress**

Recently it has been shown that NADPH oxidase-2 (NOX-2) expression is elevated in COVID-19 subjects.\(^{(92)}\) Another study has revealed that blockade of NOX-2 in macrophages leads to decreased oxidative stress.\(^{(93)}\) It is noted that proinflammatory cytokines and other agonists in endothelial cells may mobilize NOX proteins, leading to local oxidative stress and endothelial dysfunction (Appendix 1C).\(^{(94)}\) The endothelial dysfunction in COVID-19 subjects is also
caused by the production of ROS via NAD(P)H oxidase, leading to reduction in bioavailability of nitric oxide. Decreased level of nitric oxide leads to vasoconstriction, inflammation, and redox imbalance.\(^{(95)}\) It is observed that administration of NS thymoquinone improved cisplatin-induced abnormality of enzymatic and nonenzymatic antioxidant defense mechanism in rat intestine.\(^{(96)}\) It is also noted in the study of 30 postmenopausal women that consumption of both Allium sativum and NS seeds continuously for 2 months reduces the oxidative stress.\(^{(97)}\) Another study revealed that consumption of NS seeds oil with a low-calorie diet significantly reduced oxidative stress in 50 obese subjects.\(^{(97)}\)

Conclusions

COVID-19 pandemic has become a serious public health concern with high transmission rate affecting millions of lives worldwide. NS is a potential antiviral therapy for combating COVID-19 infection. Molecular docking studies have indicated that nigellidine and α -hederin are major compounds in NS which have capability to constrain COVID-19 infection. NS extract has potential to increase IL-8 levels and alter the expression of TRP genes during coronavirus infection. NS seed extracts also has potential to block cytokine storm and oxidative stress produced during COVID-19 infection. These encouraging and supportive results provided an approach to further perform in vitro and in vivo research.
