Phosphate solubilizing yeast isolated and characterized from teff rhizosphere soil collected from gojam; Ethiopia

Abstract
Phosphorous is an essential macronutrient for plant growth and development. About 95-99% present in soil insoluble form. Phosphate solubilizing microorganisms can increase soil phosphate solubility and availability. This study was aimed to identify and evaluate phosphate solubilizing yeast from Teff rhizosphere soil. Yeasts were identified using Biolog Micro station identification system. Yeast isolates were screened and transferred to biolog universal yeast agar media. Pure yeast cells were suspended in sterile water at 49±2 turbidity measured by biolog turbidimeter. 100µL transferred from each suspension into 96 wells of the biology yeast micro Plate tagged with different carbon source and incubated at 26°C for 24 to 72h and read by micro station at a single wavelength of 590nm, results were recorded and processed for identification by micro log3 software ver. 4.20.05. Above 0.5 similarities index value is acceptable species identification. Therefore biolog microstations identify nine yeast species with specific species identity. The identified yeasts were tested for phosphate solubilization by the Pikovskaya’s agar (PKV) selective media. Nine yeast species were positive in phosphate solubilizing ability, Phichia norvegensis, Cryptococcus albidos var aerius, Candida etchelisii, Cryptococcus albidos var albidos, Rhodotula aurantiacaA, Rhodotorula aurantiaca B, Cryptococcus lutesus, Cryptococcus albidos var diffuens, Cryptococcus terreus A. At 15days incubation their phosphate solubilizing index (PSI) ranges 1.72-3.35. Phichia norvegensis and Cryptococcus albidos var aerius were superior in phosphate solubilization 3.35 and 3.2 SPI respectively. Therefore these species can be candidated and exploited after further evaluation as bio fertilizers for teff productivity.

Keywords: biolog, microorganisms, microstation, phosphorus, rhizospher, soil, solubilization, teff

Introduction
Improving soil fertility is one of the most common practices in agricultural productivity for all crops. Teff [Eragrostis tef (Zucc.) Trotter] is the major indigenous cereal crop of Ethiopia, where it was originated and diversified. It is a highly demanded and a staple food grain for 60-65% of the Ethiopian people. In a country of over 80 million people, teff accounts for about 15% of all calories consumed in Ethiopia.1 More than 70-75% of Ethiopian highland soils are characterized by phosphorus deficiency.2 The deficiency is very severe in the acidic soils of the southern, southwestern and western regions. Areas Al3+ and Fe3+ high are totally incriminated with phosphorus fixation.3 Around 70% of Ethiopian vertisol have available phosphorus below 5 ppm, which is very low for supporting good teff growth and phosphorus fixation in vertisols is related more to calcium.4

Phosphorus is one of the major nutrients second to nitrogen required by plants for growth and productivity. It contributes remarkably to photosynthesis, sugar production, nucleic acid synthesis, and promotes N2 fixation in legume and energy production.5 It also increases the strength of cereal straw, promotes flower development, fruit production, stimulates root development and also essential for seed formation, stalk and stem strength, maturity and production crop quality and resistance to plant diseases.6 A greater part of soil organic and inorganic phosphorus, approximately 95-99% is present in the form of insoluble phosphates that is bound by Al or Fe in acid soils, or Ca and Mg in alkaline soils which cannot be utilized by the plants easily.7,8

Declining soil fertility as a result of continuous cropping without replenishing soil nutrients continues application of phosphate fertilizer and soil erosions is the major factors that reducing production and productivity of the teff crop in Ethiopia. Higher grain yield of teff was recorded by applying inorganic fertilizers.9 However chemical fertilizers are neither easily available nor affordable for the majority of poor Ethiopian farmers and not environmentally friendly and also the recovery rate of Phosphate fertilizer by plants is only about 10 to 30%. The remaining 70 to 90% is accumulated in soil or in the form of immobile that is bound by Al or Fe in acid soils, or Ca and Mg in alkaline soils.7,8 Such economic considerations and phosphate existence in compound form necessitate for an alternative less expensive and environmentally friendly bio fertilizer improving yield and quality of teff grain. In Ethiopia, only few studies on teff root-associated microorganisms have been undertaken. The effect of phosphate solubilizing some fungus on growth and yield of teff was studied by Asfaw.10 Inoculation of teff by vascular arbuscular mycorrhizal (VAM) and plant growth promoting rhizobacteria (PGPR) give good result on teff productivity. So previous research works tell us using bio fertilizer are better indicative to improve teff productivity to a significant level. However there are some trials on rhizobacteria and vascular arbuscular mycorrhizal using as bio fertilizer, phosphate solubilizing yeast were not studied very well.
Phosphate solubilizing microorganisms can play an important role in dissolving both of fertilizer phosphorus and bound phosphorus in the soil that is environmentally friendly and sustainable.\textsuperscript{11} Several groups of microorganisms including fungi, bacteria and actinomycetes are known as efficient P solubilizers.\textsuperscript{12} In last few decades a large array of rhizosphere bacteria and fungi including species of Azotobacter chroococcum, Bacillus subtilis, Bacillus cereus, Bacillus megaterium, Arthrobacter bacillus, Escherichia coli, Pantoea agglomerans, Pseudomonas putida, Pseudomonas aeruginosa, Enterobacter aerogenes, Microbacterium laevaniformans, and Micrococcus luteus have been identified as P-fertilizers.\textsuperscript{13} Many fungal species can solubilize rock phosphate, aluminium phosphate and tricalcium phosphate, such as Aspergillus niger, Aspergillus tubingensis, Aspergillus fumigatus, Aspergillus terreus, Aspergillus awamori, Penicillium italicum, Penicillium radicum, and Aspergillus rugulosus, Fusarium oxysporum, Curvularia lunata, Humicola sp., Sclerotium rolfsii, Pythium sp., Aerobacter aerogenes, Microbacterium laevaniformans, and Micrococcus luteus have been identified as P-fertilizers.\textsuperscript{14} Many fungal species can solubilize rock phosphate, aluminium phosphate and tricalcium phosphate, such as Aspergillus niger, Aspergillus tubingensis, Aspergillus fumigatus, Aspergillus terreus, Aspergillus awamori, Penicillium italicum, Penicillium radicum, and Aspergillus rugulosus, Fusarium oxysporum, Curvularia lunata, Humicola sp., Sclerotium rolfsii, Pythium sp., Aerobacter aerogenes, Microbacterium laevaniformans, and Micrococcus luteus have been identified as P-fertilizers.\textsuperscript{14} This study was aimed to isolate, identify and evaluating of phosphate solubilizing yeast from teff rhizosphere soil collected from Gojam farm land and selecting superior solubilizing yeast that will be candidate for bio fertilizer after further evaluation for teff crop productivity.

Materials and methods

Study area

The study was conducted in east and west Gojam in selected districts, particularly in Bichena, Bahirdar zuria, Huletejunaeeae, Denbecha, Enarge enawga, Enemay, Dejenin Amhara regional state. East Gojam Zone is bordered on the south by the Oromia Region, on the west by, on the north by south Gondar, and on the east by south Wollo; the bend of the Abay River defines the Zone’s northern, eastern and southern boundaries. 10°31’44.7”N & 37°51’10.2”E. West Gojam (Mirab Gojam) is one of the Zone in the Amhara Region of Ethiopia. West Gojam is bounded by North Gondar, on the north by Lake Tana, and the Abay River which separates it from the South Gondar, and on the east by east Gojjam. Coordinates: Latitude: 10.97379North, Longitude: 37.46814East. Gojam at Average altitude, 1788m.a.s.l. (Figure 1).

Sample collection

Seventy five teff farmland sites were selected based on five teff varieties, two soil types and 200m difference within1400-1900m.a.s.l altitude in the study area. Seventy five rhizosphere soils were collected through drillings at 5, 10, and 15cm depth. Approximately 15g of soil were taken from each depth of sampling point and a total of 45g composite soil per sampling farmland were stored in sterile sample tube and icebox during November 7-17 /2016 Figure 2 and transported microbial directorate laboratory in Ethiopian biodiversity institute to Addis Ababa and kept in +4°C until processed.

Figure 1 Map of study area.

Figure 2 Activities during teff rhizosphere soil collection and teff varieties.

Screening and isolation of yeast from teff rhizosphere soil

One gram of soil from each sample was serially diluted up to 10-6mL in distilled water. About 0.1mL inoculum sample was transferred to yeast extract peptone dextrose agar media (YPDA) by cotton swab and streaked using nichrom loop. Primary cultures were incubated for 26°C in digital incubator for 48h. Isolates were subculture twice until pure colony obtained for morphological identification. A single yeast colony was streaked to Biolog universal yeast agar (BUY agar plate, 60g/1 L) and incubated for 48h at 26°C for yeast (YT) Microplate inoculum preparation. The yeasts were identified according to the Biolog micro station reading procedure (Biolog, 1993).

Identification of colonial morphology

The colony morphology of the isolated yeast were examined after grown on yeast extract peptone dextrose agar media and biolog universal yeast agar media at 26°C for 48h and its colony morphology, form, size, elevation, margin/edge, colony color were observed using hand lens and recorded.

Identification of yeast from teffrhizosphere soil using Biolog Microstation

Pure yeast isolates were transferred to biolog universal yeast agar media and incubated at 26°C for 48h. Pure colony of yeast suspension were prepared in 9mL sterile distilled water and adjusted to 47±2T using biolog turbidimeter.100µ-L of inoculum was dispensed using digital pipettor to each of 96wells of yeast (YT) and incubated at 26°C 24-72h. The YT micro plate is tagged with 96 carbon source. An isolate ability to metabolize each carbon source is measured in the presence or absence of purple hue in the wells. Tetrazolium violet a redox dye forms a purple color when oxidized by cellular respiration of microorganisms. The YT micro plate measures both metabolic reactions as well as turbidity growth to produce identifications. YT micro plate was read by the micro station reader at 24h, 48h, and 72h at a single wavelength of 590nm. The biolog

Phosphate solubilizing yeast isolated and characterized from teff rhizosphere soil collected from gojam; Ethiopia

Identification of phosphate solubilizing microorganisms

Yeast identified by biolog micro station was tested for their phosphate solubilizing ability. Pure yeast colony was collected using a needle nose and spot at 4 quadrants on sterile solid Pikovskaya media (2.5g Ca3(PO4), 0.5g (NH4)2SO4, 0.2NaCl, 0.1g MgSO4.7H2O, 0.2g KCl, 10g glucose, 0.5g of yeast extract, 20g agar, 0.0001g MnSO4, 0.0001g FeSO4, 1000mL distilled water). Ca3(PO4)2 was used as a source of phosphate. Observations were made until the formation of a clear zone around the colonies of yeast that indicated the occurrence of phosphate dissolution. At 5days intervals solubilization index (SI) was measured using following formula:21 Yeast that formed the fastest clear areas with the greatest diameter indicates the most superior phosphate solubilizing yeast.

\[
SI = \text{colony diameter} + \text{halozone diameter}
\]

Colonial morphology

The phosphate solubilizing yeast isolates were identified based on their colony morphology depending on its pigmentation, shape, size, texture, elevation and margin. The following table summarizes the result (Table 1).

**Table 1 Colony morphology for phosphate solubilizing yeast**

| P-solubilizing fungi | Shape | Elevation | Size | Margin | Surface texture | Color |
|----------------------|-------|-----------|------|--------|----------------|-------|
| 1 Cryptococcus albidus var aerius | Irregular | Flat | Large | Lobate | Concentric | Yellow |
| 2 Cryptococcus terreus A | Irregular | Flat | Large | Undulate | Smooth | White |
| 3 Cryptococcus albidus var albidus | Entire | Pulvinate | Large | Entire | Radiate | White yellow |
| 4 Rhodotorula aurantiaca B | Irregular | Raised | Large | Undulate | Concentric | White |
| 5 Phichia norvegensis | Circular | Flat | Large | Entire | Concentric | White yellow |
| 6 Rhodotorula aurantiaca A | Rhound | Flat | Large | Undulate | Radiate | White brown |
| 7 Cryptococcus luteolus | Circular | Flat | Large | Erose | Concentric | Yellow white |
| 8 Candida etchellsii | Circular | Flat | Medium | Entire | Concentric | Yellow white |
| 9 Cryptococcus albidus vardiffluens | Entire | Flat | Large | Erose | Concentric | Yellow white |

Identification of yeast species using biolog micro station

A total of 96 yeast colonies were grown on yeast extract potato dextrose agar and counted. Pure colonies having similar morphology were clustered together in order to detect the percentage frequencies of the yeast. Representative yeast colony transferred into YT micro plate and read by biology microstation at 24, 48 and 72h incubation. The result revealed that nine yeast ≥0.5 similarity index values were identified. These are Phichia norvegensis, Cryptococcus albidus var aerius, Candida etchellsii, Cryptococcus albidus var albidus, Rhodotorula aurantiacaA, Rhodotorula aurantiaca B, Cryptococcus luteolus, Cryptococcus albidus var diffluens, Cryptococcus terreus and three yeast isolates has no species identification result. In this study Cryptococcus were the dominant species in percentage frequency (Table 2).

**Table 2 Biolog micro station yeast identification result**

| Fungus species | Probability | Similarity | Distance | Status | Yeast isolated from gojam specific districts |
|----------------|-------------|------------|----------|--------|--------------------------------------------|
| 1 Rhodotorula aurantiaca A | 100 | 0.584 | 6.48 | Identified | Bichena, Gotera Kebele |
| 2 Candida etchellsii | 78 | 0.658 | 2.34 | Identified | Awabel, Enebi chifri |
| 3 Cryptococcus luteolus | - | 0.659 | 3.19 | Identified | Dejen Zemetin Kebele |

Phosphate solubilization test

A total of 12 yeast species were evaluated for their phosphate solubilization efficiency on Pikovskaya’s agar selective media. Among those identified by micro station, nine yeast species and 3 yeast isolates with no species ID were positive for phosphate solubilization (Table 3). Their phosphate solubilization index (PSI) ranges from 1.2-3.35 within 15 days of incubation (Figure 3). *Phichia norvegensis* and *Cryptococcus albicus var aerius* were superior in phosphate solubilization with great clear zone diameter and small colony diameter 3.35 and 3.2 respectively (Table 3).

Table 3 Phosphate solubilization index (PSI)

| S. no | Fungus species isolated from teff rhizosphere soil | Phosphate solubilization index (PSI) |
|-------|---------------------------------------------------|-------------------------------------|
|       |                                                   | 5<sup>th</sup>days | 10<sup>th</sup>days | 15<sup>th</sup>days |
| 1     | Phichia norvegensis                              | 2.51                | 3                    | 3.35                |
| 2     | Cryptococcus albicus var aerius                   | 1.32                | 2.51                 | 3.2                 |
| 3     | Candida etchellsii                                | 1.76                | 2.54                 | 2.9                 |
| 4     | Cryptococcus albicus var albidus                  | 2.49                | 2.57                 | 2.9                 |
| 5     | Rhodotorula aurantiaca A                         | 1.16                | 1.8                  | 2.4                 |

Discussion

Phosphorus deficiencies are widespread on soil throughout the world and one of the limiting factors for crop productivity. Phosphorus fertilizers represent major cost for agricultural production. Many bacteria, fungi and a few actinomycetes are potential solubilizers of bound phosphates in soil thus playing an important role making it available to plants in the soluble form. Solubilization of insoluble phosphorus by microorganisms was reported by Pikovskaya. During the last two decades knowledge on phosphate solubilizing microorganisms increased significantly. In this study a total of 96 yeast isolates were screened from teff rhizosphere soil collected from Gojam, Ethiopia and 12 yeasts were read by Microstation. Nine yeasts have got full species identification (ID) and 3 with no species ID (Table 2). All yeast species evaluated for their phosphate solubilization ability on Pikovskaya (PKV) selective media. Among all 9 yeast species and 3 isolates were positive for phosphate solubilization. *Phichia norvegensis*, *Cryptococcus albicus var aerius*, *Candida etchellsii*, *Cryptococcus albicus var albidus*, *Rhodotorula aurantiaca A*, *Rhodotorula aurantiaca B*, *Cryptococcus luteolus*, *Cryptococcus albicus var diffluens*, *Cryptococcus terreus A* (Table 3). Varsha et al., reported yeast belonging to genus *Saccharomyces*, *Hansenula*, *Klokkera*, *Rhodotorula* and *Debaryomyces* spp. were phosphate solubilizing yeast. The soil yeasts *Candida tropicalis*, *Geotrichum candidum*, *Geotrichum capitatum*, *Rhodotorula minuta* and *Rhodotorula rubra* solubilized insoluble phosphate reported by Al faith. Delegen Woyessa & Fassil Assefa, reported bacteria isolated from teff rhizosphere soil from agricultural fields of Alemegna and Bushoftu Ethiopia, isolates teff rhizosphere contains a diverse flora of microorganisms. The genera were *Pseudomonas*, *Chryseomonas*, *Burkholderia*, *Bacillus*, *Brevibacillus*, *Stenotrophomonas* and *Aeromonas*. These 4 species *Bacillus subtilis*, *Burkholderia cepacia*, *Pseudomonas fluorescens*, *Bacillus coagulans* were superior phosphate solubilizer bacteria. However many rhizospheric bacteria and fungi isolated from different crop rhizosphere soil, there is little information regarding teff rhizosphere yeast and potential phosphate solubilizer yeasts. This study will confirm that there are a diverse teff rhizosphere yeast and superior phosphate solubilizer isolated from Gojam teff

Citation: Gizaw B, Tsegay Z, Tefera G, et al. Phosphate solubilizing yeast isolated and characterized from teff rhizosphere soil collected from gojam; Ethiopia. J Bacteriol Mycol Open Access. 2017;5(1):218–223. DOI: 10.15406/jbmoa.2017.05.00120
farm land (Table 3). The yeast species Rhodotula aurantiaca A are phosphate solubilizer fungi species discovered in this study are also similar with the work of Yasser et al., and Isbelia. In this study phosphate solubilization index (PSI) were measured within 5 days intervals for 15 days of incubation and they measured 1.2-3.35 PSI clear zone diameter over colony diameter ratio (Table 3). Narsian et al., reported yeast belonging to genus Saccharomyces Hansenula, Klöckera, Rhodotula and Debaryomyces exhibited highest SI (1.33-1.50). The study by Yasser et al., phosphate solubilization index recorded 1.05-1.45. A japonicus (SI=1.45), A. niger (SI=1.12), Penicillium expansum (SI=1.20), Penicillium funiculosum (SI=1.40), Penicillium variabile (SI=1.13), Penicillium purpureogenum (SI=1.30). In this study the largest solubilization index recorded by Phichia norvegensis (SI=3.35), Cryptococcus albidos var aerius (SI=3.2), Candida etchellsii (SI=2.9). The smallest solubilization index recorded by Cryptococcus terrus A (PSI, 1.72) (Figure 3 & Table 3). According to De Freitas, good phosphate solubilizers produce halos around their colonies with diameters higher than 1.5cm. Most efficient phosphate solubilizer on Povikovskaya’s agar plates with PSI = 3.29. Whereas among fungi P. canescens sho highest solubilizing index Nahas. Phosphate solubilization index (PSI) values up to 2.4 have been recorded for Aspergillus niger, with values of 3.1 for Penicillium italicum and 3.0 for Paecilomyces lilacinus. Fungal strains isolated from sugarcane and sugar beet rhizosphere showed SI in range of 1.13 to 1.59 Mahamuniet et al., Alam et al., reported PSI of the fungal strains isolated from maize rhizosphere that ranged from 1.53 to 1.80. In this study new phosphate solubilizer yeast Phichia norvegensis, Cryptococcus albidos var aerius identified from teff rhizosphere soil with superior solubilization index (PSI) 3.35 and 3.2 respectively in 15 days incubation. Therefore, these strains can be candidated and exploited as bio fertilizers through further evaluation and optimization test to increase agricultural productivity of teff crop.

Conclusion

Ninety six yeasts were screened from teffrhizosphere soil and morphologically similar isolates were clustered and representative yeast isolates were identified by biolog microstation identification system where equivalent to molecular techniques and the dominant species were Cryptococcus species. Nine yeast species and 3 yeast isolates Phichia norvegensis, Cryptococcus albidos var aerius, Candida etchellsii, Cryptococcus albidos var albidas, Rhodotula aurantiacaA, Rhodotula aurantiaca B, Cryptococcus luteolus, Cryptococcus albidos var diffuens, Cryptococcus terresus A, Yeast isolate GTGRWS18, GTS9B, GTS7C were positive for phosphate solubilization ability. Phichia norvegensis and Cryptococcus albidos var aerius were superior among the isolated fungi in solubilizing index 3.35 and 3.2 respectively and good candidate for biofertilizer after further evaluation on in vitro test, green house and field trials. The rise in the cost of chemical fertilizer, the lack of fertilizer industries in developing countries and the growing environmental issue and biodiversity loss using chemical fertilizer timely important concern using alternative ecofriendly bio fertilizer to increase yield and productivity of teff crop.

Utilization efficiency of crops for phosphate chemical fertilizer is around 30%, the remaining 70%exist in compound and bound form. Such economic considerations and phosphate existence in compound form necessitate for an alternative less expensive and environmentally friendly bio fertilizer improving yield and quality of teff grain.

Recommendation

The beneficial effects of plant growth promoting microorganisms (PGPM) have not been exoilted well. In the past some microbial inoculants prepared from Rhizobium for leguminous crops, Azotobacter and Azospirillium for cereal crops and Frankia for tree crops have been used as nitrogen providers in many developed and developing countries. However enormous interest increase in research in recent years in PGPM such as nitrogen fixer, phosphate solubilizer, pathogen suppressor. There is no well-organized microbial inoculant industry for bio fertilizer production especially for phosphate solubilizer and there is no link with researcher working on microbial bio fertilizer in Ethiopia, there for agricultural research institute, microbiologist, soil scientist agronomist, and stockholders in general must work together in depth on structural and functional diversity of PGPM and selecting superior biofertilizer, biopesticide, biostimulant to increase crop yield and productivity. Further research should be continued with selecting efficient phosphate solubilizer microorganism (PSM) isolates. These may be used for inoculum production and their inoculation effect on the plant growth must be studied in vitro, green house and field trials.

Acknowledgements

It gives me a great pleasure to acknowledge Dr. Genene Tefera for his unreserved guidance and encouragement and support in providing and facilitating the necessary equipment and extremely greatful to acknowledge Gojam zonal and district agriculture office and leader of all area in the research area who helped me guiding the study site and finally goes to Ethiopian biodiversity institute, microbial directorate for every budget grant to carry out this study and its research team for their un reserved support at laboratory and field work especially Misganaw Wasie, Endeshaw Abatneh, Endegena Aynalem, as part of research group in tireless effort in teffrhizosper soil sample collection. Lastly I acknowledged Woyenshet Lule for her kindly support especially laboratory chemicals facilitation.

Conflict of interest

The author declares no conflict of interest.

Such economic considerations and phosphate existence in compound form necessitate for an alternative less expensive and environmentally friendly bio fertilizer improving yield and quality of teff grain.
