Abstract

We present firstly the equation of motion for the photon coupled to a special bumblebee vector field in a Kerr black hole spacetime and find that the propagation of light depends on its polarization due to the birefringence phenomenon. The dependence of black hole shadow on the light’s polarization is dominated by the rotation of black hole. In the non-rotating case, we find that the black hole shadow is independent of the polarization of light. However, the status is changed in the rotating case, in which the black hole shadow depends on the light’s polarization and the coupling between bumblebee vector field and electromagnetic field. These features of black hole shadow casted by polarization lights could help us to understand the bumblebee vector field with Lorentz symmetry breaking and its interaction with electromagnetic field.

One of the most exciting events in observing black holes is that Event Horizon Telescope Collaboration \cite{1,2} released the first image of the supermassive black hole in the center of M87 galaxy at the last year. The information stored in the image has been applied extensively to study the possibility of constraining black hole parameters and extra dimension size \cite{3,4}, and to probe some fundamental physics issues including dark matter \cite{5–8}, the equivalence principle \cite{9}, and so on. Black hole shadow, caused by light rays that fall into an event horizon, is one of the most important ingredients in the image. Generally, the black hole shadow in the observer’s sky is determined by black hole, the propagation of light ray and the position of observer. It is shown that black hole shadow depends also on the polarization of light itself if we consider some interactions between electromagnetic and gravitational fields, such as Wely tensor coupling \cite{10}, which can be attributed to the birefringence phenomenon of light originating from such kinds of couplings. This interesting feature could trigger the further study of black hole shadows under interactions between electromagnetic and other fields.

It is well known that Lorentz invariance has been great of importance in many fields of the fundamental physics. However, the development of unified gauge theories and the signals from high energy cosmic rays \cite{11,12} imply that the spontaneous breaking of Lorentz symmetry may emerge in the more fundamental physics defined in a higher scale of energy. Generally, it is currently impossible directly to test such kind of physical theories with Lorentz violation through experimentation due to their higher energy scale. However, it is possible that some signals associated with the breaking of Lorentz symmetry can emerge at sufficiently low energy scales and their corresponding effects could be observed in experiments at current energy scales \cite{13}. Bumblebee model \cite{14} is a simple effective theory of gravity with Lorentz violation in the standard model extension. In this theoretical model, the spontaneous breaking of Lorentz symmetry is induced by a nonzero vacuum expectation value of a bumblebee field $B_\mu$ under a suitable potential. Recently, the bumblebee gravity model has been extensively studied in literature \cite{15–23}. An exact Schwarzschild-like black hole solution in this bumblebee gravity model is obtained and some classical tests are studied \cite{13}. The gravitational deflection angle of light \cite{24} and the Hawking radiation \cite{25} are studied in this black hole spacetime. Moreover, this black hole solution is generalized to the rotation case and the corresponding shadow \cite{26}, accretion disk \cite{27} and the deflection of particle \cite{28} around the black hole are studied. The traversable wormhole solution is also found in the framework of the bumblebee gravity theory \cite{29} and the cosmological implications of bumblebee
gravity model are further investigated in [30]. These analysis may be useful in testing the bumblebee gravity model and detecting the effects originating from the spontaneous Lorentz symmetry breaking.

From the previous analysis, the interaction between electromagnetic field and gravitational field will modify Maxwell equation and lead to that the propagation of photon in the curve spacetime depends on its polarization direction. The recent investigation shows that the coupling between axion and photon also results in the photon birefringence as photon crosses over axion matter. Axion is a compelling dark matter candidate and provides an elegant solution to the strong CP problem. The axion dark matter distribution near M87 black hole [3] and in the protoplanetary disk around a young star [31] are analyzed by using the birefringence effects of the polarization photons. However, it is an open issue how the polarization light affect the shadow of a rotating black hole. In this paper, we will consider the coupling between photon and bumblebee field to study what effect of the corresponding birefringence on the shadow of a Kerr black hole. The main reason why we here chose bumblebee field is that the equation of motions for the photons with different polarizations are not coupled together in this model, which is very critical to analyze the propagation paths of the different polarization photons and to probe the properties of black hole shadow. Moreover, we also want to see whether black hole shadow contains the information on Lorentz symmetry breaking.

The plan of our paper is organized as follows: In Sec.II, we derive equations of motion for the photons coupled to bumblebee vector field in a Kerr black hole spacetime from the modified Maxwell equation by the geometric optics approximation [32–39]. In Sec.III, we study how Kerr black hole shadow change with the polarization of light and the coupling parameter under the photon-bumblebee interaction. We end the paper with a summary.

II. EQUATION OF MOTION FOR THE PHOTONS COUPLED TO BUMBLEBEE FIELD IN A KERR BLACK HOLE SPACETIME

In this section, we will make use of the geometric optics approximation [32–39] and get the equations of motion for the photons interacted with bumblebee vector field in a Kerr black hole spacetime. The simplest action of the electromagnetic field coupled to bumblebee vector field in the curved spacetime can be expressed as

$$S = \int d^4x \sqrt{-g} \left[ \frac{R}{16\pi G} - \frac{1}{4} \left( F_{\mu\nu} F^{\mu\nu} + B_{\mu\nu} B^{\mu\nu} - 4\alpha B^\mu B^\nu F_{\mu\nu} F_\rho \right) - V(B^\mu) \right],$$

(1)

where $B_{\mu\nu}$ is bumblebee field and the corresponding strength tensor $B_{\mu\nu}$ is defined by

$$B_{\mu\nu} = \partial_\mu B_\nu - \partial_\nu B_\mu.$$

(2)
The potential \( V(B^\mu) \), induced Lorentz violation, can be expressed as

\[
V = V(B_\mu B^\mu \pm b^2),
\]

(3)

where \( b^2 \) is a positive constant. In order to ensure the breaking of the \( U(1) \) symmetry, the potential \( V(B_\mu B^\mu \pm b^2) \) is supposed to own a minimum at \( B_\mu B^\mu = \mp b^2 \). The condition \( B_\mu B^\mu = \mp b^2 \) is satisfied when the vector field has a nonzero vacuum value

\[
B_\mu = \langle B_\mu \rangle = b_\mu,
\]

(4)

with \( b_\mu b^\mu = \mp b^2 \). \( F_{\mu\nu} \) is the usual electromagnetic tensor and \( \alpha \) is a dimensionless coupling constant. With the variational method, one can find that Maxwell equation is modified as

\[
\nabla_\mu \left( F^{\mu\nu} - 2\alpha b^\mu b^\rho F_{\rho\nu} + 2\alpha b^\nu b^\rho F_{\mu\rho} \right) = 0,
\]

(5)

which means that the coupling changes propagation of electromagnetic field in background spacetime. Resorting to the geometric optics approximation, one can obtain equation of motion for a coupled photon from the corrected Maxwell equation (5). In the geometric optics approximation, the wavelength of photon \( \lambda \) is assumed to be much smaller than a typical curvature scale \( L \), but larger than the electron Compton wavelength \( \lambda_e \). This ensures that we can neglect the change of the background gravitational and electromagnetic fields with the typical curvature scale for the photon propagation (32–39). With this approximation, the electromagnetic field strength can be written as a simpler form

\[
F_{\mu\nu} = f_{\mu\nu} e^{i\theta},
\]

(6)

where \( f_{\mu\nu} \) is a slowly varying amplitude and \( \theta \) is a rapidly varying phase. It implies that the derivative term \( f_{\mu\nu;\lambda} \) is not dominated so that it can be neglected in this case. The wave vector is \( k_\mu = \partial_\mu \theta \), which can be treated as the usual photon momentum in quantum theories. With the help of the Bianchi identity

\[
D_\lambda F_{\mu\nu} + D_\mu F_{\nu\lambda} + D_\nu F_{\lambda\mu} = 0,
\]

(7)

one can obtain the constraint for the amplitude \( f_{\mu\nu} \), i.e.,

\[
k_\lambda f_{\mu\nu} + k_\mu f_{\nu\lambda} + k_\nu f_{\lambda\mu} = 0.
\]

(8)

It means that \( f_{\mu\nu} \) can be further expressed as

\[
f_{\mu\nu} = k_\mu a_\nu - k_\nu a_\mu,
\]

(9)
with a polarization vector \( a_\mu \) satisfying the condition that \( k_\mu a^\mu = 0 \). Inserting Eqs. (6) and (9) into Eq. (5), we can get that the equation of motion for the photon coupled with bumblebee vector field

\[
k_\mu k^\mu a^\nu - 2\alpha b^\rho b^\nu k_\mu a_\rho + 2\alpha b^\rho b^\nu k_\rho k_\mu a^\nu + 2\alpha b^\rho b^\nu k_\mu a_\rho = 0. \tag{10}
\]

It is obvious that the interaction with bumblebee field affects the propagation of the coupled photon in the background spacetime.

The Kerr metric describes the geometry of a rotation black hole, whose line-element can be expressed as

\[
ds^2 = -\rho^2 \frac{\Delta}{\Sigma^2} dt^2 + \frac{\rho^2}{\Delta} dr^2 + \rho^2 d\theta^2 + \frac{\Sigma^2}{\rho^2} \sin^2 \theta (d\phi - \omega dt)^2, \tag{11}
\]

with

\[
\omega = \frac{2aMr}{\Sigma^2}, \quad \rho^2 = r^2 + a^2 \cos^2 \theta, \\
\Delta = r^2 - 2Mr + a^2, \quad \Sigma^2 = (r^2 + a^2)^2 - a^2 \sin^2 \theta \Delta. \tag{12}
\]

Here the parameters \( M \) and \( a \) denote the mass and the angular momentum per unit mass of the black hole, respectively. In order to introduce a local set of orthonormal frames in Kerr black hole spacetime, one can use the vierbein fields defined by

\[
g_{\mu\nu} = \eta_{ab} e^a_\mu e^b_\nu, \tag{13}
\]

where \( \eta_{ab} \) is the Minkowski metric and the vierbeins

\[
e^a_\mu = \begin{pmatrix}
\rho \sqrt{\Delta} & 0 & 0 & -\frac{\omega \Sigma}{\rho} \sin \theta \\
0 & \rho & 0 & 0 \\
0 & 0 & \rho & 0 \\
0 & 0 & \frac{\Sigma}{\rho \sin \theta} & 0
\end{pmatrix} \tag{14}
\]

with the inverse

\[
e^\mu_a = \begin{pmatrix}
\frac{\rho \Sigma}{\sqrt{\Delta} \rho} & 0 & 0 & 0 \\
0 & \rho \sqrt{\Delta} & 0 & 0 \\
0 & 0 & \frac{1}{\rho} & 0 \\
0 & 0 & 0 & \frac{\rho \sin \theta}{\Sigma}
\end{pmatrix}. \tag{15}
\]

Making use of the relationship \( a^\mu k_\mu = 0 \), one can find that the equation of motion of the photon coupling with (10) can be simplified as a set of equations for three independent polarisation components \( a^t, a^\theta, \) and \( a^\phi \):

\[
\begin{pmatrix}
K_{11} & K_{12} & K_{13} \\
K_{21} & K_{22} & K_{23} \\
K_{31} & K_{32} & K_{33}
\end{pmatrix}
\begin{pmatrix}
a^t \\
a^\theta \\
a^\phi
\end{pmatrix} = 0. \tag{16}
\]
The coefficients $K_{ij}$, $(i, j = t, \theta, \phi)$ are very complicated and we do not list them here for simplicity. There exists the non-zero solution of Eq. (16) only if the determinant of the coefficient matrix $|K|$ is equal to zero (i.e., $|K| = 0$). However, we find that in the Kerr black hole spacetime it is difficult to find a solution satisfied $|K| = 0$ in a general case. Here, we focus on only a special case in which the bumblebee field is spacelike and has the form $b^\mu = (0, b^r, b^\theta, 0)$. We find that in this case there exist two solutions for equation (16), i.e.,

$$-(e_1^r)^2 k^r k^t + (e_\theta^1)^2 k^r k^\theta + (e^3_\theta)^2 k^\theta k^\theta + \frac{8\alpha}{1 - 2\alpha b^2} (e_1^r)^2 b^\beta b^\beta k^\theta k^\theta = 0,$$

$$-(e_1^r)^2 k^r k^t + [1 + 2\alpha (e_\theta^1)^2 b^\beta b^\beta] (e_\theta^1)^2 k^r k^\theta + [1 + 2\alpha (e^3_\theta)^2 b^\beta b^\beta] (e^3_\theta)^2 k^\theta k^\theta + (e^3_t)^2 + (e^3_\phi)^2 + 4\alpha (e_1^r)^2 b^\beta b^\beta k^\theta k^\theta = 0.$$  

(17) and (18) recover to the usual form in a Kerr spacetime in which the birefringence phenomenon vanishes when the coupling constant $\alpha = 0$, the interaction vanish and then the light-cone conditions (17) and (18) recover to the usual form in a Kerr spacetime in which the birefringence phenomenon vanishes because the photon propagation is independent of its polarization directions.

The light cone conditions (17) and (18) actually indicate that the motion of the coupled photons is non-geodesic in the Kerr metric. However, these photons can be looked as moving along the null geodesics of the effective metric $\gamma_{\mu\nu}$, i.e., $\gamma^{\mu\nu} k_{\mu} k_{\nu} = 0$. Obviously, the effective metric depends on the polarization of light, the bumblebee vector field and the coupling constant. Here we focus on only the following a special case of bumblebee vector field with $b^2 = 1$, and

$$B_\mu = \left(0, \frac{r}{\sqrt{\Delta}}, a \cos \theta, 0\right).$$

(19)

It is obvious that the tensor $B_{\mu\nu} = \partial_\mu B_\nu - \partial_\nu B_\mu = 0$ for above bumblebee field and it satisfies the equation of motion

$$\nabla_\mu B^{\mu\nu} = \frac{\partial V}{\partial x^\nu} \bigg|_{B^\mu B_\mu = 1} = 0.$$  

(20)

We find that the effective metric for the polarized light corresponded to the equations (17) or (18) is

$$ds^2 = -\rho^2 \frac{\Delta}{\Sigma^2} dt^2 + \frac{\rho^2}{\Delta W(r, \theta)} dr d\theta - \frac{4\alpha a r \cos \theta}{(1 - 2\alpha) \sqrt{\Delta} W(r, \theta)} d\theta d\phi + \frac{\rho^2}{W(r, \theta)} d\theta^2 + \frac{\Sigma^2}{\rho^2} \sin^2 \theta (d\phi - \omega dt)^2,$$

(21)

or

$$ds^2 = -\rho^2 \frac{\Delta}{\Sigma^2} dt^2 + \frac{\rho^2 + 2\alpha a^2 \cos^2 \theta}{(1 + 2\alpha) \Delta} dr^2 - \frac{2\alpha a r \cos \theta}{(1 + 2\alpha) \sqrt{\Delta}} d\theta dr + \frac{\rho^2 + 2\alpha a^2}{1 + 2\alpha} d\theta^2 + \frac{\Sigma^2}{\rho^2} \sin^2 \theta (d\phi - \omega dt)^2,$$

(22)
The change of black hole shadow with the coupling constant $\alpha$ for the metric (22). Here we set the black hole $M = 1$ and rotation parameter $a = 0$, and the observer locates in the position with $r_{\text{obs}} = 50M$ and $\theta_{\text{obs}} = \pi/2$. The figures from left to right correspond to $\alpha = -0.3, -0.2, 0, \text{ and } 0.2$, respectively.

with

$$W(r, \theta) = 1 - \frac{16\alpha^2 r^2 a^2 \cos^2 \theta}{(1 - 2\alpha)^2 \rho^4}. \quad (23)$$

The cross term $\gamma_{r\theta}$ makes the effective metric more complicated than that of the usual Kerr one. In order to avoid the singularity arising from the coupling in the effective metric, the coupling constant $\alpha$ must be limited in the range $\alpha \in (-\frac{1}{2}, \frac{1}{2})$. For a sake of simplicity, we write the effective metrics (21) and (22) as a unified form

$$ds_i^2 = -\rho_4^2 \Delta dt^2 + F_i \rho_4^2 dr^2 - 2H_i \rho_4^2 d\rho d\theta + U_i \rho_4^2 d\theta^2 + \frac{\Sigma^2}{\rho^4} \sin^2 \theta (d\phi - \omega dt)^2, \quad (24)$$

where $F_i, H_i,$ and $U_i$ are constants. Obviously, there exist two conserved quantities $E$ and $L$, which corresponds to the energy and the $z$-component of the angular momentum of the polarized photon moving in the effective effective metric (24). With the help of these two conserved quantities, the null geodesics for the effective metric (24) can be expressed as

$$\rho_4^2 i = \frac{(r^2 + a^2)(r^2 + a^2)E - aL}{\Delta} - a(aE \sin^2 \theta - L), \quad (25)$$

$$\rho_4^2 \dot{\phi} = \frac{a[(r^2 + a^2)E - aL]}{\Delta} - (aE - \frac{L}{\sin^2 \theta}), \quad (26)$$

$$F_i \rho_4^4 i^2 - 2H_i \rho_4^4 \dot{r}_i \dot{\theta}_i + U_i \rho_4^4 \dot{\theta}_i^2 = \frac{[(r^2 + a^2)E - aL]^2}{\Delta} - \left(\frac{aE \sin^2 \theta - L}{\sin \theta}\right)^2. \quad (27)$$

With these equations, we can study the propagation of the polarization light in the Kerr black hole space time and probe the properties of black hole shadow casted by the polarization lights.

III. KERR BLACK HOLE SHADOW DUE TO COUPLING BETWEEN THE PHOTON AND BUMBLEBEE VECTOR FIELD

When the rotation parameter $a$ tends to zero, the metric (21) reduces to that of the usual Schwarzschild black hole and is independent of the coupling parameter $\alpha$, which means that the polarized light moving along
the geodesics in the effective metric (21) does not affect the black hole shadow in this case. However, for the metric (22), it is related to the coupling parameter \( \alpha \) in the case with \( a = 0 \). The corresponding null geodesics (27) for the polarized light becomes

\[
\frac{r^4}{(1 + 2\alpha)} \dot{\theta}^2 = r^4 E^2 - (Q + L^2) \Delta, \tag{28}
\]

\[
r^4 \dot{\theta}^2 = Q - L^2 \cot^2 \theta, \tag{29}
\]

where \( Q \) is the Carter constant. It is obvious that in this case the photon sphere for the polarized light does not depend on the coupling and is the same as that of usual Schwarzschild case without the coupling. With two impact parameters \( \xi = \frac{L}{E} \) and \( \eta = \frac{Q}{E^2} \), we can obtain the two celestial coordinates

\[
x = - \lim_{r_0 \to \infty} r \frac{\dot{\phi}}{p^\theta}(r_0, \theta_0) = - \lim_{r_0 \to \infty} r \frac{\sqrt{g_{r\theta}} p^\phi}{\sqrt{g_{\theta\theta}} p^r}|_{(r_0, \theta_0)} = - \frac{\xi}{\sin \theta_0},
\]

\[
y = \lim_{r_0 \to \infty} r \frac{\dot{\phi}}{p^\theta}(r_0, \theta_0) = \lim_{r_0 \to \infty} r \frac{\sqrt{g_{r\theta}} p^\phi}{\sqrt{g_{\theta\theta}} p^r}|_{(r_0, \theta_0)} = \pm \sqrt{\sigma - \xi^2 \cot^2 \theta_0}, \tag{30}
\]

which are independent of the coupling constant \( \alpha \). This means that the black hole shadows casted by the polarized lights are same even if their propagation paths are different in the non-rotating case. It is also confirmed in Fig.1 where the black hole shadows in non-rotating case do not depends on the polarization of light and the coupling parameter \( \alpha \). However, the color region distribution in Fig.1 changes with the polarization of light and the parameter \( \alpha \), which means the birefringence phenomenon occurs exactly in this case without non-vanishing \( \alpha \). In other words, in the non-rotating case, the Lorentz symmetry breaking changes the propagation of polarized lights, but the black hole shadows do not contain the any information on Lorentz symmetry breaking for the selected bumblebee field (19).

Let us now focus on the nonzero \( a \) case. It is clear that Eq.(27) can not be variable-separable due to the presence of the cross term \( \dot{r} \dot{\theta} \), i.e., the \( r \)- component and \( \theta \)- component do not decouple from each other. This means that the dynamical system of two kind of polarized photons is non-integrable and the shape of black hole shadow will change. Due to the equation (27) without separable variables, we must resort to "backward ray-tracing" method [41–52] to study numerically the shadow casted by such kinds of polarization lights. In this method, the light rays are assumed to evolve from the observer backward in time and the information carried by each ray would be respectively assigned to a pixel in a final image in the observer’s sky. For the effective metric (24), one can expand the observer basis \( \{e_t, e_r, e_\theta, e_\phi\} \) as a form in the coordinate basis \( \{\partial_t, \partial_r, \partial_\theta, \partial_\phi\} \)

\[
e_\mu = e^\nu_\mu \partial_\nu, \tag{31}
\]
where the transform matrix $e_{\mu}^{\nu}$ obeys to $\gamma_{\mu\nu}e_{\alpha}^{\mu}e_{\beta}^{\nu} = \eta_{\alpha\beta}$, and $\eta_{\alpha\beta}$ is the metric of Minkowski spacetime. It is convenient to choose a decomposition associated with a reference frame with zero axial angular momentum in relation to spatial infinity \[41\]–\[54]\[54\]

\[
e_{\mu}^{\nu} = \begin{pmatrix}
\zeta & 0 & 0 & \gamma \\
0 & A^r & A^\theta & 0 \\
0 & 0 & A^\theta & 0 \\
0 & 0 & 0 & A^\phi
\end{pmatrix},
\]

(32)

where $\zeta$, $\gamma$, $A^r$, $A^\theta$, and $A^\phi$ are real coefficients. From the Minkowski normalization

\[
e_{\mu}^{\nu}e_{\nu}^{\mu} = \delta_{\mu}^{\nu},
\]

(33)

one can obtain

\[
A^r = \frac{1}{\sqrt{\gamma_{rr}}}, \quad A^\theta = \frac{1}{\sqrt{\gamma_{\theta\theta}}}, \quad A^\phi = \frac{1}{\sqrt{\gamma_{\phi\phi}}}, \quad \zeta = \sqrt{\frac{\gamma_{\phi\phi}}{\gamma_{rr} - \gamma_{\phi\phi}}},
\]

\[
A^\theta = \frac{\gamma_{\theta\theta}}{\gamma_{rr}} \sqrt{\frac{\gamma_{\theta\theta}}{\gamma_{rr} - \gamma_{\theta\theta}}}, \quad \gamma = \frac{\gamma_{\phi\phi}}{\gamma_{\theta\theta} - \gamma_{\phi\phi}} \sqrt{\frac{\gamma_{\phi\phi}}{\gamma_{rr} - \gamma_{\phi\phi}}},
\]

(34)

Therefore, one can get the locally measured four-momentum $p^\mu$ of a photon by the projection of its four-momentum $p^\mu$ onto $e_\mu^{\nu}$,

\[
p^i = -p_i = -e_i^{\nu}p_\nu, \quad p^\phi = p_\phi = e_i^{\nu}p_\nu.
\]

(35)

With the help of Eq.(33), the locally measured four-momentum $p^\phi$ can be further written as

\[
p^i = \zeta E - \gamma L, \quad p^\phi = \frac{1}{\sqrt{\gamma_{rr}}}p_r - \frac{\gamma_{\theta\phi}}{\gamma_{\theta\theta} - \gamma_{\phi\phi}} p_\theta,
\]

\[
p^\phi = \frac{1}{\sqrt{\gamma_{\phi\phi}}} p_\phi, \quad p^\phi = \frac{1}{\sqrt{\gamma_{\phi\phi}}} L.
\]

(36)

Repeating the similar operations in Refs.\[41\]–\[52\]\[52\], one can obtain the position of photon’s image in observer’s sky

\[
x = -r_{\text{obs}} \frac{p^\phi}{p^\phi} = -r_{\text{obs}} \frac{\sqrt{\gamma_{rr} - \gamma_{\phi\phi}}} {\sqrt{\gamma_{rr} - \gamma_{\phi\phi} (F_i^2 - H_i^2)}},
\]

\[
y = r_{\text{obs}} \frac{p^\phi}{p^\phi} = r_{\text{obs}} \frac{\sqrt{\gamma_{rr} - \gamma_{\phi\phi} (F_i^2 - H_i^2)}} {\sqrt{\gamma_{rr} - \gamma_{\phi\phi} (F_i^2 - H_i^2 (F_i^2 - H_i^2))}},
\]

(37)

where the spatial position of observer is set to $(r_{\text{obs}}, \theta_{\text{obs}})$. In Figs.\[2\]–\[3\] we present black hole shadow for the different coupling constant $\alpha$ and rotation parameter $a$. Comparing the color regions distributions with the same parameters in Figs.\[2\]–\[3\] or Figs.\[4\]–\[5\] we find that the propagation of light in the black hole spacetime also depends on the polarization of light, which is similar to those in the non-rotating case. However, in the rotating case, the black hole shadow else depends the coupling constant $\alpha$ and the polarization of light.
FIG. 2: The change of black hole shadow with the coupling constant $\alpha$ for the metric (21). Here we set the black hole mass $M = 1$ and rotation parameter $a = 0.5$, and the observer locates in the position with $r_{\text{obs}} = 50M$ and $\theta_{\text{obs}} = \pi/2$. The figures from left to right correspond to $\alpha = -0.3$, $-0.2$, $0$, and $0.2$, respectively.

FIG. 3: The change of black hole shadow with the coupling constant $\alpha$ for the metric (22). Here we set the black hole mass $M = 1$ and rotation parameter $a = 0.5$, and the observer locates in the position with $r_{\text{obs}} = 50M$ and $\theta_{\text{obs}} = \pi/2$. The figures from left to right correspond to $\alpha = -0.3$, $-0.2$, $0$, and $0.2$, respectively.

FIG. 4: The change of black hole shadow with the coupling constant $\alpha$ for the metric (21). Here we set the black hole mass $M = 1$ and rotation parameter $a = 0.998$, and the observer locates in the position with $r_{\text{obs}} = 50M$ and $\theta_{\text{obs}} = \pi/2$. The figures from left to right correspond to $\alpha = -0.3$, $-0.2$, $0$, and $0.2$, respectively.

FIG. 5: The change of black hole shadow with the coupling constant $\alpha$ for the metric (22). Here we set the black hole mass $M = 1$ and rotation parameter $a = 0.998$, and the observer locates in the position with $r_{\text{obs}} = 50M$ and $\theta_{\text{obs}} = \pi/2$. The figures from left to right correspond to $\alpha = -0.3$, $-0.2$, $0$, and $0.2$, respectively.
FIG. 6: The enlargement of the left panel in Fig.5. It shows that there exist the eyebrow shape shadow and the self-similar fractal structures in black hole shadow.

which differs from those in the previous non-rotating case. From Figs.2,5 we find that the negative coupling constant $\alpha$ elongates the shadow along $y-$axial direction, and make the shadow size increase for the fixed rotation parameter $a$ in the both cases (21) and (22). The positive $\alpha$ squeezes the shadow along $y-$axis, but the shadow size is decreased. Moreover, we find that the shadow casted by the polarization light propagating in the effective metric (21) has a smaller deformation than in the effective metric (22). With the increase of the rotation parameter, the effect of polarized lights on the black hole shadow becomes more distinctly.

It is obvious that the effect of Lorentz symmetry breaking on black hole shadow increases with the absolute value $\alpha$ in this case. Moreover, from the left panel in Fig.5 we can find the eyebrow shape shadow and the self-similar fractal structures of black hole shadow arising from the chaotic lensing of polarized lights, which is also shown in Fig.6. These features of black hole shadow casted by polarization lights could help us to understand deeply the bumblebee vector fields with Lorentz symmetry breaking and their corresponding interactions with electromagnetic field.

IV. SUMMARY

In this paper, we have investigated firstly the equation of motion for the photon coupled to the three special kinds of bumblebee vector fields in a Kerr black hole spacetime and then probed further the black hole shadow. In the non-rotating case, we find that the black hole shadow is independent of the polarization of light and the coupling constant even if the polarized lights propagate along different paths. This means that Lorentz symmetry breaking arising from bumblebee vector field (19) does not affect the black hole shadow in these two special cases. However, in the rotating case, the status is changed because that the black hole shadow also depends the polarization of light and the coupling constant $\alpha$. The negative coupling constant $\alpha$ elongates the shadow along $y-$axial direction, and make the shadow size increase for the fixed rotation parameter $a$. The positive $\alpha$ squeezes the shadow along $y-$axis, but the shadow size is decreased. Moreover, we find that the
shadow casted by the polarization light propagating in the effective metric (21) has a smaller deformation than in the effective metric (22). The effect of polarized lights on the black hole shadow becomes more distinctly in the case with the quicker rotation and the stronger coupling. With the development of the new generation Event Horizon Telescope, these features of black hole shadow casted by polarization lights may be detected in the future and could help us to understand the bumblebee vector field with Lorentz symmetry breaking and its interaction with electromagnetic field in the nature.
