REAL RATIONAL CURVES IN GRASSMANNIANS

FRANK SOTTILE

Abstract. Fulton asked how many solutions to a problem of enumerative geometry can be real, when that problem is one of counting geometric figures of some kind having specified position with respect to some general fixed figures. For the problem of plane conics tangent to five general conics, the (surprising) answer is that all 3264 may be real. Similarly, given any problem of enumerating $p$-planes incident on some general fixed subspaces, there are real fixed subspaces such that each of the (finitely many) incident $p$-planes are real. We show that the problem of enumerating parameterized rational curves in a Grassmannian satisfying simple (codimension 1) conditions may have all of its solutions be real.

Introduction

Fulton asked how many solutions to a problem of enumerative geometry can be real, when that problem is one of counting geometric figures of some kind having specified position with respect to some general fixed figures [5]. For the problem of plane conics tangent to five general conics, the (surprising) answer is that all 3264 may be real [12]. Similarly, given any problem of enumerating $p$-planes incident on some general fixed subspaces, there are real fixed subspaces such that each of the (finitely many) incident $p$-planes are real [14]. We show that the problem of enumerating parameterized rational curves in a Grassmannian satisfying simple (codimension 1) conditions may have all of its solutions be real.

This problem of enumerating rational curves on a Grassmannian arose in at least two distinct areas of mathematics. The number of such curves was predicted by the formula of Vafa and Intriligator [19, 7] from mathematical physics. It is also the number of complex dynamic compensators which stabilize a particular linear system, and the enumeration was solved in this context [11, 10]. The question of real solutions also arises in systems theory [3]. Our proof, while exploiting techniques from systems theory, has no direct implications for the problem of real dynamic output compensation.

1. Statement of results

We work with complex algebraic varieties and ask when $a$ priori complex solutions to an enumerative problem are real. Fix integers $m, p > 1$ and $q \geq 0$. Set $n := m + p$. 

Date: 23 April 1999.

Key words and phrases. Enumerative geometry, Quantum cohomology, Grassmannian, Dynamic output compensation, Homotopy Continuation.

Research at MSRI supported in part by NSF grant DMS-9701755.
Let \( \mathbf{G} \) be the Grassmannian of \( p \)-planes in \( \mathbb{C}^n \). The space \( \mathcal{M}_q \) of maps \( M : \mathbb{P}^1 \to \mathbf{G} \) of degree \( q \) has dimension \( N := pm + qn \). If \( L \) is an \( m \)-plane and \( s \in \mathbb{P}^1 \), then the collection of all maps \( M \) satisfying \( M(s) \cap L \neq \{0\} \) is an irreducible subvariety of codimension 1. We study the following enumerative problem:

\[ \text{(1)} \quad \text{Given general points } s_1, \ldots, s_N \text{ in } \mathbb{P}^1 \text{ and general } m \text{-planes } L_1, \ldots, L_N \text{ in } \mathbb{C}^n, \text{ how many maps } M \in \mathcal{M}_q \text{ satisfy } M(s_i) \cap L_i \neq \emptyset \text{ for } i = 1, \ldots, N? \]

Rosenthal [13] interpreted the solutions as a linear section of a projective embedding of \( \mathcal{M}_q \), and Ravi, Rosenthal, and Wang [11, 10] show that the degree of its closure \( \mathcal{K}_q \) in this embedding is

\[ \delta \ := \ (-1)^{q(n+1)}N! \sum_{\nu_1 + \cdots + \nu_p = q} \frac{\prod_{i<j}(j-i+n(\nu_j-\nu_i))}{\prod_{j=1}^p(m+j+n\nu_j-1)!}. \]

Thus, if there are finitely many solutions, then their number (counted with multiplicity) is at most \( \delta \). The difference between \( \delta \) and the number of solutions counts points common to both the linear section and the boundary \( \mathcal{K}_q - \mathcal{M}_q \) of \( \mathcal{K}_q \). Since \( \mathbf{G} \) is a homogeneous space, an application of Kleiman’s Theorem [8] shows there are finitely many solutions and no multiplicities. Bertram [4] uses explicit methods (a moving lemma) to show there are finitely many solutions and also no points in the boundary of \( \mathcal{Q}_q \), and hence none in the boundary of \( \mathcal{K}_q \). He also computes the small quantum cohomology ring of \( \mathbf{G} \), which gives algorithms for computing \( \delta \) and other intersection numbers involving rational curves on a Grassmannian.

When the \( s_i \) and \( L_i \) are real, not all of these solutions are defined over the real numbers. We show there are real \( s_i \) and \( L_i \) for which each of the \( \delta \) maps are real.

**Theorem 1.** There exist real \( m \)-planes \( L_1, \ldots, L_N \) in \( \mathbb{R}^n \) and points \( s_1, \ldots, s_N \in \mathbb{P}^1_\mathbb{R} \) so that there are exactly \( \delta \) maps \( M : \mathbb{P}^1 \to \mathbf{G} \) of degree \( q \) which satisfy \( M(s_i) \cap L_i \neq \emptyset \) for each \( i = 1, \ldots, N \), and each of these are real.

Our proof is elementary in that it argues from the equations for the locus of maps \( M \) which satisfy \( M(s) \cap L \neq \emptyset \). A consequence is that we obtain fairly explicit choices of \( s_i \) and \( L_i \) which give only real maps, which we discuss in Section 4. Also, our proof uses neither Kleiman’s Theorem nor Bertram’s moving lemma, and thus it provides a new and elementary proof that there are \( \delta \) solutions to the enumerative problem [4].

2. The Quantum Grassmannian

The space \( \mathcal{M}_q \) of maps \( \mathbb{P}^1 \to \mathbf{G} \) of degree \( q \) is a smooth quasi-projective algebraic variety. A smooth compactification is provided by a quot scheme \( \mathcal{Q}_q \) [8]. By definition, there is a universal exact sequence

\[ 0 \to \mathcal{S} \to \mathbb{C}^n \otimes \mathcal{O} \to \mathcal{T} \to 0 \]

of sheaves on \( \mathbb{P}^1 \times \mathcal{Q}_q \) where \( \mathcal{S} \) is a vector bundle of degree \( -q \) and rank \( p \). Twisting the determinant of \( \mathcal{S} \) by \( \mathcal{O}_{\mathbb{P}^1}(q) \) and pushing forward to \( \mathcal{Q}_q \) induces a Plücker map

\[ \mathcal{Q}_q \to \mathbb{P}(\Lambda^p \mathbb{C}^n \otimes H^0(\mathcal{O}_{\mathbb{P}^1}(q))^*) \]

The difference between \( \mathcal{M}_q \) and \( \delta \) is that there are exactly \( \delta \) maps of degree \( q \) which satisfy \( M(s_i) \cap L_i \neq \emptyset \). A consequence is that we obtain fairly explicit choices of \( s_i \) and \( L_i \) which give only real maps, which we discuss in Section 4. Also, our proof uses neither Kleiman’s Theorem nor Bertram’s moving lemma, and thus it provides a new and elementary proof that there are \( \delta \) solutions to the enumerative problem [4].

2. The Quantum Grassmannian

The space \( \mathcal{M}_q \) of maps \( \mathbb{P}^1 \to \mathbf{G} \) of degree \( q \) is a smooth quasi-projective algebraic variety. A smooth compactification is provided by a quot scheme \( \mathcal{Q}_q \) [8]. By definition, there is a universal exact sequence

\[ 0 \to \mathcal{S} \to \mathbb{C}^n \otimes \mathcal{O} \to \mathcal{T} \to 0 \]

of sheaves on \( \mathbb{P}^1 \times \mathcal{Q}_q \) where \( \mathcal{S} \) is a vector bundle of degree \( -q \) and rank \( p \). Twisting the determinant of \( \mathcal{S} \) by \( \mathcal{O}_{\mathbb{P}^1}(q) \) and pushing forward to \( \mathcal{Q}_q \) induces a Plücker map

\[ \mathcal{Q}_q \to \mathbb{P}(\Lambda^p \mathbb{C}^n \otimes H^0(\mathcal{O}_{\mathbb{P}^1}(q))^*) \]
which is the analog of the Plücker embedding of $G$. The Plücker map is an embedding of $\mathcal{M}_q$, and so its image $\mathcal{K}_q$ provides a different compactification of $\mathcal{M}_q$. We call $\mathcal{K}_q$ the quantum Grassmannian. (In [4], this space is called the Uhlenbeck compactification). Our proof of Theorem 1 exploits some of its structures that were elucidated in work in systems theory.

The Plücker map fails to be injective on the boundary $Q_q - \mathcal{M}_q$ of $Q_q$. Indeed, Bertram [1] constructs a $\mathbb{P}^{p-1}$ bundle over $\mathbb{P}^1 \times Q_{q-1}$ that maps onto the boundary, with its restriction over $\mathbb{P}^1 \times \mathcal{M}_{q-1}$ an embedding. On this projective bundle, the Plücker map factors through the base $\mathbb{P}^1 \times Q_{q-1}$ and the image of a point in the base is $s \cdot S$, where $s$ is the section of $\mathcal{O}_{\mathbb{P}^1}(1)$ vanishing at $s \in \mathbb{P}^1$ and $S$ is the image of a point in $Q_{q-1}$ under its Plücker map. This identifies the image of the exceptional locus of the Plücker map with the image of $\mathbb{P}^1 \times \mathcal{K}_{q-1}$ in $\mathcal{K}_q$ under a map $\pi$ (given below).

More concretely, a point in $Q_q$ may be (non-uniquely) represented by a $p \times n$-matrix $M$ of forms in $s, t$, with homogeneous rows and whose maximal minors have degree $q$. The image of such a point under the Plücker map is the collection of maximal minors of $M$. The maps in $\mathcal{M}_q$ are represented by matrices whose maximal minors have no common factors: Given such a matrix $M$, the association

$$\mathbb{P}^1 \ni (s, t) \longmapsto \text{row space } M(s, t)$$

defines a map of degree $q$.

The collection $\binom{[n]}{p}$ of $p$-subsets of $\{1, \ldots, n\}$ index the maximal minors of $M$. For $\alpha \in \binom{[n]}{p}$ and $0 \leq a \leq q$, the coefficients $z_{\alpha, a}$ of $s^a t^{q-a}$ in the $\alpha$th maximal minor of $M$ provide Plücker coordinates for maps in $\mathcal{M}_q$, and for the space $\mathbb{P}(\bigwedge^p \mathbb{C}^n \otimes H^0(\mathcal{O}_{\mathbb{P}^1}(q))^*)$. Let $C_q := \{\alpha(a) \mid \alpha \in \binom{[n]}{p}, 0 \leq a \leq q\}$ be the indices of these Plücker coordinates. Then the image of the exceptional locus in $\mathcal{K}_q$ is the image of the (birational) map $\pi : \mathbb{P}^1 \times \mathcal{K}_{q-1} \to \mathcal{K}_q$ defined by

$$\pi : ([A, B], (x_{\beta(b)} \mid \beta(b) \in C_{q-1})) \longmapsto (A x_{\alpha(a)} - B x_{\alpha(a-1)} \mid \alpha(a) \in C_q).$$

The relevance of the quantum Grassmannian $\mathcal{K}_q$ to the enumerative problem [4] is seen by considering the condition for a map $M \in \mathcal{M}_q$ to satisfy $M(s, t) \cap L \neq \{0\}$ where $L$ is an $m$-plane in $\mathbb{C}^n$ and $(s, t) \in \mathbb{P}^1$. If we represent $L$ as the row space of a $m \times n$ matrix, also written $L$, then this condition is

$$0 = \det \begin{bmatrix} L \\ M(s, t) \end{bmatrix} = \sum_{\alpha \in \binom{[n]}{p}} f_{\alpha}(s, t) l_{\alpha},$$

the second expression given by Laplace expansion of the determinant along the rows of $M$. Here, $l_{\alpha}$ is the appropriately signed maximal minor of $L$. If we expand the forms $f_{\alpha}(s, t)$ in this last expression, we obtain

$$\sum_{\alpha(a) \in C_q} z_{\alpha(a)} s^a t^{q-a} l_{\alpha} = 0,$$
a linear equation in the Plücker coordinates of $M$. Thus the solutions $M \in \mathcal{M}_q$ to the enumerative problem (I) are a linear section of $\mathcal{M}_q$ in its Plücker embedding, and so the degree $\delta$ of $K_q$ provides an upper bound on the number of solutions.

The set $C_q$ of Plücker coordinates has a natural partial order

$$\alpha^{(a)} \geq \beta^{(b)} \iff a \geq b, \text{ and if } a - b < p, \text{ then } \alpha_{a-b+1} \geq \beta_1, \ldots, \alpha_p \geq \beta_{p+1-b+a} .$$

The poset $C_q$ is graded with the rank, $|\alpha^{(a)}|$, of $\alpha^{(a)}$ equal to $an + \sum_i \alpha_i - i$. Figure 1 shows $C_1$ when $p = 2$ and $m = 3$. Given $\alpha^{(a)} \in C_q$, define the quantum Schubert variety

$$Z_{\alpha^{(a)}} := \{ z = (z_{\beta^{(b)}}) \in K_q \mid z_{\beta^{(b)}} = 0 \text{ if } \beta^{(b)} \nleq \alpha^{(a)} \} .$$

Let $\mathcal{H}_{\alpha^{(a)}}$ be the hyperplane defined by $z_{\alpha^{(a)}} = 0$. The main technical result we use is the following.

**Proposition 2** ([10, 11]). Let $\alpha^{(a)} \in C_q$. Then

(i) $Z_{\alpha^{(a)}}$ is an irreducible subvariety of $K_q$ of dimension $|\alpha^{(a)}|$.

(ii) The intersection of $Z_{\alpha^{(a)}}$ and $\mathcal{H}_{\alpha^{(a)}}$ is generically transverse, and

$$Z_{\alpha^{(a)}} \cap \mathcal{H}_{\alpha^{(a)}} = \bigcup_{\beta^{(b)} \leq \alpha^{(a)}} Z_{\beta^{(b)}} .$$

**Figure 1.** $C_1$. 

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure1}
\caption{Figure 1. $C_1$.}
\end{figure}
Another proof of (ii) is given in [17], which shows (ii) is an ideal-theoretic equality. From (ii) and Bézout’s theorem, we obtain the following recursive formula for the degree of $Z_{\alpha(a)}$

$$\deg Z_{\alpha(a)} = \sum_{B^{(b)} \leq \alpha(a)} \deg Z_{\beta(b)}.$$ 

Since the minimal quantum Schubert variety is a point, we deduce the main result of [11]:

**Corollary 3.** The degree $\delta$ of $K_q$ is the number of maximal chains in the poset $C_q$.

Closed formulas are given for $\delta$ in [10, 11], the source of the formula (3), as well as the number $\deg Z_{\alpha(a)}$ of maximal chains below $\alpha(a)$.

### 3. Proof of Theorem 1

Let $L(s, t)$ be the $m$-plane osculating the parameterized rational normal curve

$$\gamma : (s, t) \in \mathbb{P}^1 \mapsto (s^{n-1}, ts^{n-2}, \ldots, t^{n-2}s, t^{n-1}) \in \mathbb{P}^{n-1}$$

at the point $\gamma(s, t)$. Then $L(s, t)$ is the row space of the $m \times n$ matrix of forms with rows $\gamma(s, t), \gamma'(s, t), \ldots, \gamma^{(m-1)}(s, t)$, the derivative taken with respect to the parameter $t$. Write $L(s, t)$ for this matrix. For $\alpha \in \binom{[n]}{p}$, the maximal minor of $L(s, t)$ complementary to $\alpha$ is $(-1)^{|\alpha|} s^{(m)}l_{\alpha} s^{|\alpha|} t^{mp - |\alpha|}$, where $|\alpha| := \sum_i \alpha_i - i$ and $(-1)^{|\alpha|} l_{\alpha}$ is the corresponding maximal minor of $L(1, 1)$. Let $H(s, t)$ be the pencil of hyperplanes given by the linear form

$$\Lambda(s, t) := \sum_{\alpha(a) \in C_q} z_{\alpha(a)} l_{\alpha} s^{|\alpha(a)|} t^{N - |\alpha(a)|}.$$ 

Let $M$ be a matrix representing a curve in $M_q$. Then

$$\det \begin{bmatrix} L(s, t) \\ M(s^n, t^n) \end{bmatrix} = s^{(m)} \sum_{\alpha(a) \in C_q} z_{\alpha(a)} s^{an} t^{(q-a)n} l_{\alpha} s^{|\alpha|} t^{mp - |\alpha|} = s^{(m)} \Lambda(s, t).$$

Thus $M_q \cap H(s, t)$ consists of all maps $M : \mathbb{P}^1 \to G$ of degree $q$ which satisfy $M(s^n, t^n) \cap L(s, t) \neq \{0\}$.

Theorem 1 is a consequence of the following two theorems.

**Theorem 4.** There exist positive real numbers $t_1, \ldots, t_N$ such that for any $\alpha(a) \in C_q$, the intersection

$$Z_{\alpha(a)} \cap H(1, t_1) \cap \cdots \cap H(1, t_{|\alpha(a)|})$$

is transverse with all points of intersection real.

**Theorem 5.** If $t_1, \ldots, t_k \in \mathbb{C}$ are distinct, then for any $\alpha(a) \in C_q$, the intersection

$$(4) \quad Z_{\alpha(a)} \cap H(1, t_1) \cap \cdots \cap H(1, t_k)$$

is proper in that it has dimension $|\alpha(a)| - k$. 

REAL RATIONAL CURVES IN GRASSMANNIANS

5
Proof of Theorem 4. By Theorem 4 there exist positive real numbers \( t_1, \ldots, t_N \) (necessarily distinct) so that the intersection

\[
\mathcal{K}_q \cap \mathcal{H}(1, t_1) \cap \cdots \cap \mathcal{H}(1, t_N)
\]

is transverse and consists of exactly \( \delta \) real points. We show all these points lie in \( \mathcal{M}_q \), and thus are maps \( M : \mathbb{P}^1 \to \mathbb{G} \) of degree \( q \) satisfying \( M(1, t_i^q) \cap L(1, t_i) \neq \{0\} \) for \( i = 1, \ldots, N \), which proves Theorem 4.

Recall the map \( \pi : \mathbb{P}^1 \times \mathcal{K}_{q-1} \to \mathcal{K}_q \) whose image is the complement of \( \mathcal{M}_q \) in \( \mathcal{K}_q \). Then

\[
\pi^* \mathcal{H}(s, t) = \sum_{\alpha(a) \in \mathcal{C}_q} (Ax_{\alpha(a)} - Bx_{\alpha(a-1)}) l_{\alpha} s^{\alpha(a)} t^{N - |\alpha(a)|}.
\]

Hence, if \( \mathcal{H}'(s, t) \) is the pencil of hyperplanes in the Plücker space of \( \mathcal{K}_{q-1} \) defining the locus of \( M \in \mathcal{M}_{q-1} \) satisfying \( M(s^n, t^n) \cap L(s, t) \neq \{0\} \), then

\[
\pi^* \mathcal{H}(s, t) = (At^n - Bs^n) \mathcal{H}'(s, t).
\]

Thus any point in (3) not in \( \mathcal{M}_q \) is the image of a point \( ([A, B], M) \) in \( \mathbb{P}^1 \times \mathcal{K}_{q-1} \) satisfying \( \pi^* \mathcal{H}(1, t_i) = (At_i^n - B) \mathcal{H}'(1, t_i) \) for each \( i = 1, \ldots, N \). As the \( t_i \) are positive and distinct, such a point can only satisfy \( At_i^n - B = 0 \) for one \( i \). Thus \( M \in \mathcal{K}_{q-1} \) lies in at least \( N - 1 \) of the hyperplanes \( \mathcal{H}'(1, t_i) \). Since \( N - 1 \) exceeds the dimension \( N - n \) of \( \mathcal{K}_{q-1} \), there are no such points \( M \in \mathcal{K}_q \), by Theorem 5 for maps of degree \( q - 1 \).

\[ \square \]

Proof of Theorem 5. For any \( t_1, \ldots, t_k \), the intersection (4) has dimension at least \( |\alpha(a)| - k \). We show it has at most this dimension, if \( t_1, \ldots, t_k \) are distinct.

Suppose \( k = |\alpha(a)| + 1 \) and let \( z \in Z_{\alpha(a)} \). Then \( z_{\beta(b)} = 0 \) if \( \beta(b) \not\leq \alpha(a) \) and so the form \( \Lambda(1, t)(z) \) defining \( \mathcal{H}(1, t) \) is divisible by \( t^{N - |\alpha(a)|} \) with quotient

\[
\sum_{\beta(b) \leq \alpha(a)} z_{\beta(b)} b^{\alpha(a)} t^{\beta(b)}.
\]

This is a non-zero polynomial in \( t \) of degree at most \( |\alpha(a)| \) and thus it vanishes for at most \( |\alpha(a)| \) distinct \( t \). It follows that (4) is empty for \( k > |\alpha(a)| \).

If \( k \leq |\alpha(a)| \) and \( t_1, \ldots, t_k \) are distinct, but (4) has dimension exceeding \( |\alpha(a)| - k \), then completing \( t_1, \ldots, t_k \) to a set of distinct numbers \( t_1, \ldots, t_{|\alpha(a)|+1} \) would give a non-empty intersection in (4), a contradiction.

\[ \square \]

Proof of Theorem 6. We construct the sequence \( t_i \) inductively. If we let \( \alpha = 1 < 2 < \cdots < p - 1 < p + 1 \), then \( Z_{\alpha(0)} \) is a line. Indeed, it is isomorphic to the set of \( p \)-planes containing a fixed \( (p - 1) \)-plane and lying in a fixed \( (p + 1) \)-plane. By Theorem 5, \( Z_{\alpha(0)} \cap \mathcal{H}(1, t) \) is then a single, necessarily real, point, for any real number \( t \). Let \( t_1 \) be any positive real number.
Suppose we have positive real numbers $t_1, \ldots, t_k$ with the property that for any $\beta^{(b)}$ with $|\beta^{(b)}| \leq k$,

$$Z_{\beta^{(b)}} \cap \mathcal{H}(1, t_1) \cap \cdots \cap \mathcal{H}(1, t_{|\beta^{(b)}|})$$

is transverse with all points of intersection real.

Let $\alpha^{(a)}$ be an index with $|\alpha^{(a)}| = k + 1$ and consider the 1-parameter family $Z(t)$ of schemes defined for $t \neq 0$ by $Z_{\alpha^{(a)}} \cap \mathcal{H}(1, t)$. For $t \neq 0$, if we restrict the form $\Lambda(1, t)$ to $z \in Z_{\alpha^{(a)}}$, then, after dividing out $t^{|\alpha^{(a)}|}$, we obtain

$$z_{\alpha^{(a)}} + \sum_{\beta^{(b)} \leq \alpha^{(a)}} z_{\beta^{(b)}} l_{\beta} t^{|\alpha^{(a)}| - |\beta^{(b)}|} .$$

Thus $Z(0)$ is

$$Z_{\alpha^{(a)}} \cap \mathcal{H}_{\alpha^{(a)}} = \bigcup_{\beta^{(b)} \leq \alpha^{(a)}} Z_{(\beta, d)} ,$$

by Proposition 2 (ii).

**Claim:** The cycle

$$Z(0) \cap \mathcal{H}(1, t_1) \cap \cdots \cap \mathcal{H}(1, t_k)$$

is free of multiplicities.

If not, then there are two components $Z_{\beta^{(b)}}$ and $Z_{\gamma^{(c)}}$ of $Z(0)$ such that

$$Z_{\beta^{(b)}} \cap Z_{\gamma^{(c)}} \cap \mathcal{H}(1, t_1) \cap \cdots \cap \mathcal{H}(1, t_k)$$

is nonempty. But this contradicts Theorem 3, as $Z_{\beta^{(b)}} \cap Z_{\gamma^{(c)}} = Z_{\delta^{(d)}}$, where $\delta^{(d)}$ is the greatest lower bound of $\beta^{(b)}$ and $\gamma^{(c)}$ in $C_q$, and so $\dim Z_{\delta^{(d)}} < \dim Z_{\beta^{(b)}} = k$.

From the claim, there is an $\epsilon_{\alpha^{(a)}} > 0$ such that if $0 \leq t \leq \epsilon_{\alpha^{(a)}}$, then

$$Z(t) \cap \mathcal{H}(1, t_1) \cap \cdots \cap \mathcal{H}(1, t_k)$$

is transverse with all points of intersection real. Set

$$t_{k+1} := \min \{ \epsilon_{\alpha^{(a)}} : |\alpha^{(a)}| = k + 1 \} .$$

4. **Further Remarks**

From our proof of Theorem 3, we obtain a rather precise choice of $s_i$ and $L_i$ in the enumerative problem which give only real maps. By $\forall t_1 > t_2 > \cdots > t_N > 0$, we mean

$$\forall t_1 > 0 \ \exists \epsilon_2 > 0 \ \forall \epsilon_2 > t_2 > 0 \ \cdots \ \exists \epsilon_N > 0 \ \forall \epsilon_N > t_N > 0 .$$

**Corollary 6.** $\forall t_1 > t_2 > \cdots > t_N > 0$, each of the $\delta$ maps $M : \mathbb{P}^1 \to G$ of degree $q$ which satisfy $M(1, t_i) \cap L(1, t_i^{1/m}) \neq \{0\}$ for $i = 1, \ldots, N$ are real.

When $q = 0$, there is substantial evidence [15] that this choice of $t_1, \ldots, t_N$ is too restrictive. B. Shapiro and M. Shapiro have the following conjecture:

**Conjecture.** Suppose $q = 0$. Then for generic real numbers $t_1, \ldots, t_m$ all of the finitely many $p$-planes $H$ which satisfy $H \cap L(1, t_i) \neq \{0\}$ are real.

In contrast, when $q > 0$, the restriction $\forall t_1 > t_2 > \cdots > t_N > 0$ is necessary. We observe this in the case when $q = 1, p = m = 2$, so $N = 8$ and $\delta = 8$. That is, for
parameterized curves of degree 1 in the Grassmannian of 2-planes in \( \mathbb{C}^4 \). Here, the choice of \( t_i = i \) in (4) gives no real maps, while the choice \( t_i = t^6 \) gives 8 real maps.

We briefly describe that calculation. There are 12 Plücker coordinates \( z_{ij(a)} \) for \( 1 \leq i < j \leq 4 \) and \( a = 0, 1 \). If we let \( f_{ij} := tz_{ij(0)} + sz_{ij(1)} \), then

\[
f_{14}f_{23} - f_{13}f_{24} + f_{12}f_{34} = 0,
\]
as \( f_{ij}(s, t) \in \mathbb{G} \) for all \( s, t \). The coefficients of \( t^2 \), \( st \), and \( s^2 \) in this expression give three quadratic relations among the \( z_{ij(a)} \):

\[
\begin{align*}
z_{14(0)}z_{23(0)} - z_{13(0)}z_{24(0)} + z_{12(0)}z_{34(0)}, \\
z_{12(1)}z_{34(0)} - z_{13(1)}z_{24(0)} + z_{14(1)}z_{23(0)} + z_{23(1)}z_{14(0)} - z_{24(1)}z_{13(0)} + z_{34(1)}z_{12(0)}, \\
z_{14(1)}z_{23(1)} - z_{13(1)}z_{24(1)} + z_{12(1)}z_{34(1)},
\end{align*}
\]
and these constitute a Gröbner basis for the homogeneous ideal of \( \mathbb{K}_1 \).

Here, the form \( \Lambda \) is

\[
\begin{align*}
t^8z_{12(0)} - 2t^7z_{13(0)} + t^6z_{14(0)} + 3t^6z_{23(0)} - 2t^5z_{24(0)} + t^4z_{34(0)} \\
+ t^4z_{12(1)} - 2t^3z_{13(1)} + t^2z_{14(1)} + 3t^2z_{23(1)} - 2t \ z_{24(1)} + \ z_{34(1)}.
\end{align*}
\]
We set \( z_{34(1)} = 1 \) and work in local coordinates. Then the ideal generated by the 3 quadratic equations and 8 linear relations \( \Lambda(t_i) \) for \( i = 1, \ldots, 8 \) defines the 8 solutions to (5). We used Maple V.5 to generate these equations and then compute a univariate polynomial in the ideal, which had degree 8. This polynomial had no real solutions when \( t_i = i \), but all 8 were real when \( t_i = t^6 \). (Elimination theory guarantees that the number of real solutions equals the number of real roots of the eliminant.)

We describe how the enumerative problem (4) arises in systems theory (see also [3]). A physical system (e.g. a mechanical linkage) with \( m \) inputs and \( p \) measured outputs whose evolution is governed by a system of linear differential equations is modeled by a \( m \times n \)-matrix \( L(s) \) of real univariate polynomials. The largest degree of a maximal minor of this matrix is the MacMillan degree, \( r \), of the evolution equation. Consider now controlling this linear system by output feedback with a dynamic compensator. That is, a \( p \)-input, \( m \)-output linear system \( M \) is used to couple the \( m \) inputs of the system \( L \) to its \( p \) outputs. The resulting closed system has characteristic polynomial

\[
\varphi(s) := \begin{bmatrix} L(s) \\ M(s) \end{bmatrix},
\]
and the roots of \( \varphi \) are the natural frequencies or poles of the closed system. The dynamic pole assignment problem asks, given a system \( L(s) \) and a desired characteristic polynomial \( \varphi \), can one find a (real) compensator \( M(s) \) of MacMillan degree \( q \) so that the resulting closed system has characteristic polynomial \( \varphi \)? That is, if \( s_1, \ldots, s_{r+p} \) are the roots of \( \varphi \), which \( M \in \mathcal{M}_q \) satisfy

\[
\det \begin{bmatrix} L(s_i) \\ M(s_i) \end{bmatrix} = 0, \quad \text{for } i = 1, 2, \ldots, r + p?
\]

In the critical case when \( r + q = mp + qn \), this is an instance of the enumerative problem (4). When the degree \( \delta \) is odd, then for a real system \( L \) and a real characteristic polynomial \( \varphi \), there will be at least one real dynamic compensator. Part of
the motivation for [10] was to obtain a formula for $\delta$ from which its parity could be deduced for different values of $q, m,$ and $p$.

From this description, we see that the choice of planes $L_i$ that arise in the dynamic pole placement problem are $N = mp + qn$ points on a rational curve of degree $mp + (n - 1)q$ in the Grassmannian of $m$-planes in $\mathbb{C}^n$. In contrast, the planes of Theorem 4 (and hence of Theorem 1) arise as $N$ points on a rational curve of degree $mp$. Only when $q = 0$ (the case of static compensators) is there any overlap. While our proof of Theorem 1 owes much to systems theory, it has no direct implications for the problem of real dynamic output compensation.

Our method of proof of Theorem 1 (like that in [16]) was inspired by the numerical Pieri homotopy algorithm of [6] for computing the solutions to (1) when $q = 0$. Likewise, the explicit degenerations of intersections of the $\mathcal{H}(s, t)$ that we used, and more generally Proposition 2 (ii), can be used to construct an optimal numerical homotopy algorithm for finding the solutions to (1). This is in exactly the same manner as the explicit degenerations of intersections of special Schubert varieties of [14] were used to construct the Pieri homotopy algorithm of [6].

We close with one open problem concerning the enumeration of rational curves on a Grassmannian. For a point $s \in \mathbb{P}^1$ and any Schubert variety $\Omega$ of $G$, consider the quantum Schubert variety $\Omega(s)$ of curves $M \in \mathcal{M}_q$ satisfying $M(s) \in \Omega$. The quantum Schubert calculus gives algorithms to compute the number of curves $M \in \mathcal{M}_q$ which lie in the intersection of an appropriate number of these $\Omega(s)$, and we ask when it is possible to have all solutions real. A modification of the proof of Theorem 4 shows that this is the case when all except possibly 2 are hypersurface Schubert varieties. In every case we have been able to compute, all solutions may be real.
