THE TOPOLOGICAL STRUCTURE OF THE SPACE
OF ALGEBRAIC VARIETIES

H. BLAINE LAWSON, JR.

The intention of this note is to announce some recent results concerning
the homotopy type of the Chow variety of projective algebraic varieties. We
begin by discussing the case of complex projective n-space P^n.

For fixed integers d ≥ 1 and p, 0 ≤ p < n, let C_{p,d}(P^n) denote the set
of effective p-cycles of degree d in P^n. This is defined to be the family
of all finite sums c = \sum n_\alpha V_\alpha, where for each \alpha, n_\alpha is a positive inte­
ger and V_\alpha \subset P^n is an irreducible subvariety of dimension p, and where
degree(c) = \sum n_\alpha degree(V_\alpha) = d. The set C_{p,d}(P^n) itself carries the struc­
ture of a projective algebraic variety. In particular it has a natural topology.

The spaces C_{p,d}(P^n), for distinct values of d, are conventionally considered
to be mutually disjoint. However, if we fix a “distinguished” p-dimensional
linear subspace l_0 \subset P^n, we obtain a natural sequence of topological embed­
ddings,

\cdots \subset C_{p,d}(P^n) \subset C_{p,d+1}(P^n) \subset \cdots,

given at each level by mapping c to c + l_0. We can then consider the union of
these spaces

C_p(P^n) = \lim_{d \to \infty} C_{p,d}(P^n)

endowed with the weak limit topology. This is the topology in which a set
C is closed if and only if the intersections C \cap C_{p,d}(P^n) are closed for all d.
Note that C_p(P^n) is an abelian topological semigroup with unit [l_0]. Our first
result is the following.

THEOREM 1. For all n and p, 0 ≤ p < n, there is a homotopy equivalence

C_p(P^n) \cong K(Z, 2) \times K(Z, 4) \times \cdots \times K(Z, 2(n-p)),

where K(Z, l) denotes the standard Eilenberg–Mac Lane space.

We recall that for an integer l and a finitely generated abelian group G,
the Eilenberg–Mac Lane space K(G, l) is a countable CW complex uniquely
defined up to homotopy type by the requirement that: \pi_l(K(G, l)) ≅ G and
\pi_m(K(G, l)) = 0 for m ≠ l. The space K(G, l) classifies the functor H^l(\cdot; G),
i.e., there is a natural isomorphism H^l(X; G) ≅ [X, K(G, l)] for any finite
complex X. Under this equivalence the cohomology of K(G, l) is carried over

to cohomology operations. For this reason the cohomology of $K(\mathbb{Z}, l)$ (and $K(\mathbb{Z}_m, l)$) was computed in detail in the 1950s.

There are two special cases of Theorem 1 which are worth noting.

**EXAMPLE.** ($p = n - 1$). One can easily see that $C_{n-1}(P^n) \cong P^\infty$, i.e., infinite-dimensional complex projective space, written as a monotone union of finite-dimensional linear subspaces and given the weak topology. The homotopy equivalence $P^\infty \sim K(\mathbb{Z}, 2)$ is elementary and well known.

**EXAMPLE.** ($p = 0$). The space $C_0(P^n)$ corresponds to the infinite symmetric product as defined by Dold and Thom, and in this case Theorem 1 is just a special case of their classical results [2, 3].

It should be remarked that the author was led to Theorem 1 in part by an old conjecture of H. Federer, which was based on the work of Dold and Thom and was proved by F. Almgren in 1962 [1].

Theorem 1 has a substantial generalization which is formulated as follows. Fix a linear embedding $P^n \subset P^{n+k}$ ($k \geq 1$) and choose a linear subspace $P^{k-1} \subset P^{n+k}$ disjoint from $P^n$. Projecting away from $P^{k-1}$ and onto $P^n$ makes $P^{n+k} - P^{k-1}$ into a holomorphic vector bundle

$$\pi: P^{n+k} - P^{k-1} \to P^n$$

of rank $k$ ($k$ copies of $O(1)$). Given any closed set $X \subset P^n$ we define its **complex $k$-fold suspension** to be the set

$$\mathcal{Y}^k X = \pi^{-1}(X).$$

Note that $\mathcal{Y}^k X$ is just the union of all lines joining $X$ to $P^{k-1}$, i.e., the "complex join" $X \times_{C} P^{k-1}$. When $k = 1$, $\mathcal{Y} X$ is the Thom space of the hyperplane bundle $O(1)$ restricted to $X$. In general, $\mathcal{Y}^k(X) = \mathcal{Y}((\mathcal{Y}(...(\mathcal{Y}X)...)))$ is obtained by iterating this Thom construction.

If $X \subset P^n$ is an algebraic variety, so is $\mathcal{Y}^k X$. In fact $\mathcal{Y}^k X$ is defined by the same polynomials considered now to have $k$ additional "secret" variables. The map of algebraic sets $V \to \mathcal{Y}^k V$ extends naturally to algebraic cycles. In fact, if $l_0^p \subset P^n$ is our distinguished $p$-dimensional linear subspace, we set $l_0^{p+k} = \mathcal{Y}^k l_0^p$ and obtain a map

$$\mathcal{Y}^k: C_p(P^n) \to C_{p+k}(P^{n+k}).$$

Suppose now that $X \subset P^n$ is a closed subset which contains $l_0$, and define

$$C_p(X)^\wedge = \{c \in C_p(P^n) : c \subset X\}.$$

By "$c \subset X" we mean that $c$ can be written as $c = \sum n_{\alpha} V_{\alpha}$ where $V_{\alpha} \subset X$ for all $\alpha$. Let $C_p(X)$ denote the connected component of $C_p(X)^\wedge$ containing $l_0$.

**THEOREM 2.** For any algebraic subvariety $X \subset P^n$ with $l_0 \subset X$, and for all $k \geq 1$, the embedding

$$\mathcal{Y}^k: C_p(X) \to C_{p+k}(\mathcal{Y}^k X)$$

is a homotopy equivalence.

Specializing to the case where $p = 0$ and $X = P^n$ and applying the result of Dold and Thom, we recapture Theorem 1 from Theorem 2.
The assumption that $l_0 \subset X$ is always fulfilled when $p = 0$. Hence, for every variety $X$ and every integer $k \geq 0$ there is a homotopy equivalence

$$C_0(X) \overset{h.e.}{\longrightarrow} C_k(\mathfrak{C} X).$$

From the theorem of Dold and Thom we immediately conclude the following:

**COROLLARY 3.** For any connected algebraic variety $X \subset P^n$ there exist natural isomorphisms

$$\pi_*(C_k(\mathfrak{C} X)) \overset{\sim}{\rightarrow} H_*(X; \mathbb{Z})$$

for all $k \geq 0$.

Analogous results hold for the space of cycles reduced mod $m$. Let $X \subset P^n$ be a closed subset with $l_0 \subset X$, and let $m$ be a positive integer. We denote by $C_p(X) \otimes \mathbb{Z}_m$ the group of algebraic $p$-cycles in $X$ with $\mathbb{Z}_m(= \mathbb{Z}/m\mathbb{Z})$-coefficient, modulo the cyclic subgroup $\mathbb{Z}_m \cdot l_0$. $C_p(X) \otimes \mathbb{Z}_m$ carries a natural topology as the quotient of topological groups $G_p(X)/mG_p(X)$ where $G_p(X) \supset C_p(X)$ is the group extending $C_p(X)$ and defined by considering cycles with arbitrary integer coefficients. This topology is also defined by the flat norm on $C_p(X) \otimes \mathbb{Z}_m$ considered as a subset of the integral $2p$-currents modulo $m$. (See [4, 4.2].) The definition given above extends to this case and we have the following result.

**THEOREM 4.** For any algebraic subvariety $X \subset P^n$ with $l_0 \subset X$ and for all integers $k \geq 0$ and $m \geq 2$, the embedding

$$\mathfrak{C}^k : C_p(X) \otimes \mathbb{Z}_m \rightarrow C_{p+k}(\mathfrak{C} X) \otimes \mathbb{Z}_m$$

is a homotopy equivalence.

**COROLLARY 5.** For any connected algebraic variety $X \subset P^n$ there are natural isomorphisms

$$\pi_*(C_k(\mathfrak{C} X) \otimes \mathbb{Z}_m) \overset{\sim}{\rightarrow} H_*(X; \mathbb{Z}_m)$$

for all $k \geq 0$ and $m \geq 2$.

**COROLLARY 6.** For each $n$ and $p$, $0 \leq p < n$, and for each $m \geq 2$, there is a homotopy equivalence

$$C_p(P^n) \otimes \mathbb{Z}_m \overset{h.e.}{\longrightarrow} K(\mathbb{Z}_m, 2) \times K(\mathbb{Z}_m, 4) \times \cdots \times K(\mathbb{Z}_m, 2(n - p)).$$

Suppose now that $X$ and $Y$ are subvarieties of $P^n$ with $l_0 \subset Y \subset X$. Every algebraic $p$-cycle $c \subset X$ can be written uniquely in the form $c' + c''$ where $c' \subset Y$ and where $c''$ has no component contained in $Y$. Two such cycles $c_1, c_2 \subset X$ are said to be equivalent (mod $Y$) if $c_1' = c_2'$. The set of equivalence classes is denoted $C_p(X, Y)$. Note that $C_p(X, Y) = C_p(X)/C_p(Y)$, i.e., $C_p(X, Y)$ is the space of maximal orbits of $C_p(Y)$ acting by translations on $C_p(X)$.

THEOREM 7. For any pair of algebraic subvarieties \( X, Y \subset \mathbb{P}^n \) with \( l_0 \subset Y \subset X \) and for all integers \( k \geq 0 \), the map
\[
\mathcal{Y}_k : \mathcal{C}_p(X,Y) \to \mathcal{C}_{p+k}(\mathcal{Y}_k X, \mathcal{Y}_k Y)
\]
is a homotopy equivalence.

The analogous statement is true for \( p \)-cycles with \( \mathbb{Z}_m \)-coefficients.

COROLLARY 8. Let \( X \) and \( Y \) be connected varieties as in Theorem 7. Then there exist natural isomorphisms
\[
\pi_* (\mathcal{C}_k(\mathcal{Y}_k X, \mathcal{Y}_k Y)) \to H_*(X,Y;\mathbb{Z}),
\]
\[
\pi_* (\mathcal{C}_k(\mathcal{Y}_k X, \mathcal{Y}_k Y) \otimes \mathbb{Z}_m) \to H_*(X,Y;\mathbb{Z}_m),
\]
for all \( k \geq 0 \) and \( m \geq 2 \).

REMARK 9. From the nature of the proofs it seems possible that the results above could carry over to projective varieties defined over more general fields.

REMARK 10. It seems likely that there exists a sequence of integers \( N_d \to \infty \), depending on \( p \) and \( n \), such that the inclusion \( \mathcal{C}_{p,d}(\mathbb{P}^n) \to \mathcal{C}_p(\mathbb{P}^n) \) is \( N_d \)-connected. There does, in fact, exist such a sequence so that the inclusion has a right homotopy inverse through this range. Hence Theorem 1 applies to give results about the connected components of the classical Chow variety.

SKETCH OF THE PROOFS. We consider only the basic case where \( \mathcal{Y}_k : \mathcal{C}_p(\mathbb{P}^n) \to \mathcal{C}_{p+1}(\mathbb{P}^{n+1}) \). We introduce an intermediate space \( I \equiv \{ c \in \mathcal{C}_{p+1}(\mathbb{P}^{n+1}); \text{c has no component contained in } \mathbb{P}^n \} \). The argument breaks into two parts.

Step 1. The inclusion \( \mathcal{Y}_k : \mathcal{C}_p(\mathbb{P}^n) \to I \) is a homotopy equivalence. We show in fact that \( \mathcal{C}_p(\mathbb{P}^n) \) is a deformation retract of \( I \). The deformation is given by the action of the linear flow which pulls away from \( \mathbb{P}^n \) and toward the polar point \( x_0 = \mathbb{P}^0 \).

Step 2. The inclusion \( i : I \subset \mathcal{C}_{p+1}(\mathbb{P}^{n+1}) \) is a homotopy equivalence. We show here that the map \( i_* : \pi_m I \to \pi_m \mathcal{C}_{p+1}(\mathbb{P}^{n+1}) \) is an isomorphism for all \( m \geq 0 \). This is the more subtle part of the argument, the part which requires passing to high degrees. Let us consider the question of the surjectivity of \( i_* \). Suppose \( f : S^m \to \mathcal{C}_{p+1}(\mathbb{P}^{n+1}) \) is a continuous map (in fact a PL map for some triangulation of \( \mathcal{C}_{p+1}(\mathbb{P}^{n+1}) \)). We show that there is an integer \( d_f \) such that for all \( d \geq d_f \) the map \( \tilde{f} : S^m \to \mathbb{P}^n \) is homotopic to a map \( \tilde{f} : S^m \to \mathbb{P}^{n+1} \). (This will clearly prove the surjectivity of \( i_* \).) The argument goes as follows. Fix a linear embedding \( \mathbb{P}^{n+1} \subset \mathbb{P}^{n+2} \) and a point \( x_{\infty} \in \mathbb{P}^{n+2} \). The projection \( \pi : \mathbb{P}^{n+2} \to \mathbb{P}^{n+1} \) makes \( \mathbb{P}^{n+2} - \{ x_{\infty} \} \) into a complex line bundle.

Fix \( d \in \mathbb{Z}^+ \) and let \( \text{Div}^d \) denote the set of divisors of degree \( d \) on \( \mathbb{P}^{n+2} \) which do not meet \( x_{\infty} \). Given \( D \in \text{Div}^d \) and any \( c \in \mathcal{C}_{p+1}(\mathbb{P}^{n+1}) \) we can define a lifting of the cycle \( d \cdot c \) to \( D \) by setting
\[
\phi_D(d \cdot c) = \pi^{-1}(c) \cap D.
\]
Scalar multiplication by \( t \) in the line bundle \( \mathbb{P}^{n+2} - \{ x_{\infty} \} \) transforms \( D \) to a new divisor \( tD \), and \( \lim_{t \to 0} \phi_t D(d \cdot c) = d \cdot c \).
We now choose a second point \( x_1 \in \overline{x_0 x_\infty} \) and let \( \pi_1 : \mathbb{P}^{n+2} - \{ x_1 \} \rightarrow \mathbb{P}^{n+1} \) be the associated projection. If \( x_1 \notin tD \) for \( 0 \leq t \leq 1 \) we can define a homotopy

\[
\Psi_t : d \cdot \mathcal{C}_{p+1}(\mathbb{P}^{n+1}) \rightarrow \mathcal{C}_{p+1}(\mathbb{P}^{n+1})
\]

by setting

\[
\Psi_t = \pi_1 \circ \phi_{tD}.
\]

The map \( \Psi_0 \) is the identity on \( d \cdot \mathcal{C}_{p+1}(\mathbb{P}^{n+1}) \). Furthermore, for any given cycle \( c \), we will have \( \Psi_t(c) \subseteq I \) provided \( c \) has no component which lies in the divisor \( \alpha(tD) = \pi((tD) \cap \pi_1^{-1}(\mathbb{P}^n)) \subseteq \mathbb{P}^{n+1} \). It is elementary to show that given \( f : S^m \rightarrow \mathcal{C}_{p+1}(\mathbb{P}^{n+1}) \) there exists \( D \in \text{Div}_d \) so that \( f(x) \) has no component in \( \alpha(tD) \) for any \( x \in S^m \) and any \( t, 0 \leq t \leq 1 \). It follows that \( \Psi_t(df(S^m)) \subseteq I \) for \( 0 < t \leq 1 \), and surjectivity is proved.

The proof of the injectivity of \( i_* \) is similar.

The general case follows from the same argument given for the specific one.

The proof of Theorem 4 comes down to showing that the map \( \mathcal{C}_p(X) \rightarrow \mathcal{C}_p(X)/m \cdot \mathcal{C}_p(X) = \mathcal{C}_p(X) \otimes \mathbb{Z}_m \) is a quasifibration. Full details will appear elsewhere.
