Algebras of Quantum Variables for Loop Quantum Gravity

V. The localised holonomy-flux cross-product *-algebra

August 19, 2011

Abstract

In the project AQV [9] the issue of quantum constraints, KMS-states and algebras of quantum configuration and momentum variables in Loop Quantum Gravity has been argued. There a physical algebra has been required to contain complete observables and the quantum constraints, or at least the quantum constraints are affiliated with this algebra. In this context a first conjecture for a physical algebra is presented in this article. A new *-algebra for LGQ, which is called the localised holonomy-flux cross-product *-algebra, is studied. A suggestion for a physical *-algebra, which contains the localised holonomy-flux cross-product *-algebra, a modified quantum Hamilton constraint, a localised quantum diffeomorphism constraint and even a modified quantum Master constraint, is given.

1 Introduction

In [8] an extended overview about the project *Algebras of Quantum Variables in LQG* has been presented. This article will now focus on the issue of quantum constraints and KMS-theory in LQG. KMS-theory has been studied for von Neumann algebras in [7] Section 6.5. There the holonomy-flux von Neumann algebra has been invented. The construction is based on the commutative Weyl $C^\ast$-algebra for surfaces, which has been introduced in [3] Sect.: 3.3 or [7] Sect.: 6.3, and a certain representation of this $C^\ast$-algebra on the limit Hilbert space $\mathcal{H}_\infty$. The holonomy von Neumann algebra is given by the analytic holonomy $C^\ast$-algebra and a representation on the Hilbert space $\mathcal{H}_\infty$. But the concept of KMS-states is not naturally available for these von Neumann algebras associated to the Weyl $C^\ast$-algebra for surfaces or the analytic holonomy $C^\ast$-algebra. One can show that even in both cases the von Neumann algebras are not in standard form. KMS-theory is also available in the context of $C^\ast$-algebras. It has been shown in [7] Sect.: 6.5 that there are no KMS-states of the Weyl $C^\ast$-algebra for surfaces or the analytic holonomy $C^\ast$-algebra with respect to an automorphism group defined by a Lie algebra-valued quantum flux operator. Consequently for the algebras derived in [7] Chapt.: 6.7, Sect.: 8.1-8.3, [9] [10] [11] a KMS-theory is not easy to achieve. Hence new ideas are interesting to study.

Indeed the analysis of algebras in [9,11] [13] has shown that new algebras can be defined. In this article such a new $\ast$-algebra is developed in section 2. This algebra is called the localised holonomy-flux cross-product $\ast$-algebra. This algebra is a certain cross-product algebra and is derived similarly to the holonomy-flux cross-product $\ast$-algebra in [7] Sect.: 8.2, [11].

The new idea is to locate the algebraic objects in particular the algebras. The new construction of the new quantum algebras is also available for non-localised algebraic objects and can be easily extracted from the development. Remark that if matter fields come into the play, the author suggests to locate the algebras of quantum variables and the matter algebras simultaneously. The geometric objects like quantum flux operators, which are defined in section 2.3, are always localised on surfaces. Moreover, the holonomies are localised along paths or graphs. The bisections are maps from a certain set of vertices in a fixed manifold $\Sigma$ to paths that start at a given vertex in the set of vertices. Consequently, also bisections are somehow localised objects. The definition of these new objects is presented in section 2.2.3. Furthermore, the important fact is that paths and surfaces intersect each other in vertices. Hence a discretised surface set $\hat{S}_d$, which contains only fixed sets of vertices, is proposed in section 2.1. The localisation of quantum algebras means that algebra elements have distinguishing properties if they depend or do not depend on this discretised surface set. For the implementation of this idea the configuration space is divided in section 2.2.2 into two main parts. One of them is constructed from holonomies along paths that start or end at some given surface and is called the localised part of the configuration space. The other part is build from holonomies along paths that do not intersect any surface in this surface set. Hence, the first configuration space is localised on surfaces, while the second is not. Furthermore, there are two different $\ast$-algebras of quantum holonomy variables presented in section 2.1. One $\ast$-algebra is constructed on the localised part of the configuration space and a convolution product between functions depending on this space. In particular, the $\ast$-subalgebra of central functions on the localised part of the configuration space is used. The other $\ast$-algebra is given by the original analytic holonomy $\ast$-algebra, but is restricted to non-localised paths. These $\ast$-algebras are completed to different $C^\ast$-algebras and the $C^\ast$-tensor product of these two $C^\ast$-algebras defines the new localised analytic holonomy $C^\ast$-algebra. The $C^\ast$-algebra of central functions on the localised part of the configuration space is called the localised part of the localised analytic holonomy $C^\ast$-algebra. Similarly to the $\ast$-derivations of the analytic holonomy $C^\ast$-algebra [11] Sect.: 4, [7] Sect.: 8.4.2 in section 3.1 $\ast$-derivations of this new $C^\ast$-algebra are presented.

There are some new flux operators, which are defined as difference operators between Lie algebra-valued quantum flux operators on different graphs in 2.3, and which are called the localised and discretised flux operators associated to surfaces. The main difference between the original Lie algebra-valued quantum flux operator, and the localised and discretised Lie algebra-valued flux operator both restricted to a fixed graph is that, the second operator is only non-trivial on paths, which are not contained in a certain subgraph. The localised enveloping flux algebra associated to a surface set is derived from the localised and discretised flux operators. Furthermore, there exists an action of this new localised and discretised flux operator on the $C^\ast$-algebra of central functions on the localised part of the configuration space.

In [11,7] the theory of an abstract cross-product $\ast$-algebra has been used to define a new holonomy-flux cross-product $\ast$-algebra. This construction is also used for the definition of two new localised algebras. One algebra is based on the $\ast$-algebra of central functions on the localised part of the configuration space and the other is derived from the localised analytic holonomy $\ast$-algebra. The abstract cross-product $\ast$-algebra,
which is obtained from the localised enveloping flux algebra associated to a surface set and the \( C^\ast\)-algebra of central functions on the localised part of the configuration space, is called the \emph{localised part of the localised holonomy-flux cross-product \( *\)-algebra}. The \emph{localised holonomy-flux cross-product \( *\)-algebra} is given by the abstract cross-product \( *\)-algebra, which is obtained by the the localised analytic holonomy \( *\)-algebra and the localised enveloping flux algebra associated to a surface set. There are several localised holonomy-flux cross-product \( *\)-algebras for different surface sets. A \("\)-representation of this new \( C^\ast\)-algebra is given similarly to the representation of the holonomy-flux cross-product \( *\)-algebra in section \[3.2\] \( C^\ast\)-dynamical systems are studied in section \[3.3\]. Since such dynamical systems are related to KMS-states, these particular states are studied. There are certain \( C^\ast\)-algebras, which admit a KMS-state. Furthermore, there is a KMS-theory available for \( O^\ast\)-algebra presented by Inoue \[6\], which can be used in a further work to analyse the full or parts of the localised holonomy-flux cross-product \( *\)-algebra. Indeed one can show that the localised holonomy-flux cross-product \( *\)-algebra is an \( O^\ast\)-algebra. Furthermore, there is also a construction of a \( C^\ast\)-algebra, which will be called the \emph{localised holonomy-flux cross-product \( C^\ast\)-algebra} in future work, in analogy to the holonomy-flux cross-product \( C^\ast\)-algebra derived in \[10, 17\]. Then a KMS-theory for this new \( C^\ast\)-algebra will be studied.

In this project, a first attempt for a study of the Hamilton constraint as a generator of an automorphism group is studied. This constraint plays a fundamental role in the definition of dynamics in LQG. The object is for example derived from a volume operator in the work of Thiemann \[17\]. In this article a modified volume group is studied. This constraint plays a fundamental role in the definition of dynamics in LQG. The object

In the construction of the Hamilton constraint as a generator the following facts are used, too. Consider the Lie holonomy algebra, which is constructed from the localised configuration space restricted to a graph \( \Gamma \) and which is identified with the product group \( G^{|\Sigma|} \) of a compact connected Lie group \( G \). This Lie algebra acts on the \( C^\ast\)-algebra of central functions on the localised configuration space restricted to a graph, too. Then the \( C^\ast\)-algebra of central functions admits KMS-states with respect to this action. The \emph{modified quantum Hamilton constraint restricted to a graph} is given by

\[
\exp(H^+_{\Gamma}, H_{\Gamma}) := (h_A(\alpha) - h_A(\alpha)^{-1}) h_A(\gamma)[h_A(\gamma)^{-1}, Q(V)_{d}]
\]

The \emph{modified quantum Hamilton constraint} is defined in the project \( AQV \) as the limit

\[
H := \lim_{i \to \infty} \sum_{\Gamma} \exp(H^+_{\Gamma}, H_{\Gamma}) \text{ of a sum over subgraphs of a graph of the modified quantum Hamilton constraint restricted to a graph. Note that, the limit graph is assumed to contain an infinite countable set of subgraphs.}
\]

The next step is to show that, this modified quantum Hamilton constraint is well-defined and is given as the generator of a strongly continuous one-parameter group of automorphisms on the localised part of the localised analytic holonomy \( C^\ast\)-algebra. The analysis of parts of the modified quantum Hamilton constraint shows that, the convergence of the limit in the norm-topology is not obvious and is related to the structure of the discretised quantum volume operator \( Q(V)_{d} \). Summarising, the norm-convergence of the limit of \( H \) is not easy to derive. The author conjectures that this limit converges and does not depend on a particular Hilbert space representation of the modified quantum Hamilton constraint.

Thiemann has proposed in \[16,17\] a Master constraint instead of using a set of constraints. Hence in the project \( AQV \) a modified quantum Master constraint is suggested. The ideas are the following. In \[8, 9, 10\] translations defined by bisections of finite path groupoids or finite graph systems play a fundamental role. The most general operators, which depend on bisections of finite graph systems that preserve a discretised surface set \( S_{\tilde{\Delta}} \) associated to a surface set \( \tilde{\Sigma} \), are denoted by \( D_{\tilde{S}_d, \Gamma}^{\sigma} \) and are called the \emph{localised quantum diffeomorphism constraints restricted to a graph}. The adjoint operator is denoted by \( D_{\tilde{S}_d, \Gamma}^{\sigma, * \ast} \). For example such operators can be defined similarly to elements of the holonomy-flux-graph-diffeomorphism cross-product \( C^\ast\)-algebra. The idea for these quantum constraints is to implement the complicated relations between the classical spatial diffeomorphism constraints and the classical Hamilton constraints on the quantum level.

Then the \emph{modified quantum Master constraint} is defined to be sum of the \emph{localised quantum diffeomorphism constraint}, which is given by

\[
D_{\tilde{S}_d} := \lim_{N \to \infty} \sum_{i=1}^{N} \sum_{\sigma_{i}} D_{\tilde{S}_d, \Gamma_{i}}^{\sigma_{i}, \ast} \cdot D_{\tilde{S}_d, \Gamma_{i}}^{\sigma_{i}}
\]

and the modified quantum Hamilton constraint \( H \).
In the article [11] the holonomy-flux cross-product $^*$-algebra has been presented, this algebra is comparable with the holonomy-flux $^*$-algebra, which has been developed in [13]. A comparison of the localised holonomy-flux cross-product $^*$-algebra and the holonomy-flux cross-product $^*$-algebra is presented in a table in section 4.

2 The basic quantum operators

2.1 Finite path groupoids and graph systems

Let $c : [0, 1] \to \Sigma$ be continuous curve in the domain $[0, 1]$, which is (piecewise) $C^k$-differentiable ($1 \leq k \leq \infty$), analytic ($k = \omega$) or semi-analytic ($k = \omega I$) in $[0, 1]$ and oriented such that the source vertex is $c(0) = s(c)$ and the target vertex is $c(1) = t(c)$. Moreover assume that, the range of each subinterval of the curve $c$ is a submanifold, which can be embedded in $\Sigma$. An edge is given by a reparametrisation invariant curve of class (piecewise) $C^k$. The maps $s_{\Sigma}, t_{\Sigma} : P\Sigma \to \Sigma$ where $P\Sigma$ is the path space are surjective maps and are called the source or target map.

A set of edges $\{e_i\}_{i=1,...,N}$ is called independent, if the only intersections points of the edges are source $s_{\Sigma}(e_i)$ or target $t_{\Sigma}(e_i)$ target points. Composed edges are called paths. An initial segment of a path $\gamma$ is a path $\gamma_1$ such that there exists another path $\gamma_2$ and $\gamma = \gamma_1 \circ \gamma_2$. The second element $\gamma_2$ is also called a final segment of the path $\gamma$.

Definition 2.1. A graph $\Gamma$ is a union of finitely many independent edges $\{e_i\}_{i=1,...,N}$ for $N \in \mathbb{N}$. The set $\{e_1,...,e_N\}$ is called the generating set for $\Gamma$. The number of edges of a graph is denoted by $|\Gamma|$. The elements of the set $V_\Gamma := \{s_{\Sigma}(e_k), t_{\Sigma}(e_k)\}_{k=1,...,N}$ of source and target points are called vertices.

A graph generates a finite path groupoid in the sense that, the set $P_\Gamma \Sigma$ contains all independent edges, their inverses and all possible compositions of edges. All the elements of $P_\Gamma \Sigma$ are called paths associated to a graph. Furthermore the surjective source and target maps $s_{\Sigma}$ and $t_{\Sigma}$ are restricted to the maps $s, t : P_\Gamma \Sigma \to V_\Gamma$, which are required to be surjective.

Definition 2.2. Let $\Gamma$ be a graph. Then a finite path groupoid $P_\Gamma \Sigma$ over $V_\Gamma$ is a pair $(P_\Gamma \Sigma, V_\Gamma)$ of finite sets equipped with the following structures:

(i) two surjective maps $s, t: P_\Gamma \Sigma \to V_\Gamma$, which are called the source and target map,
(ii) the set $P_\Gamma \Sigma^2 := \{(\gamma_i, \gamma_j) \in P_\Gamma \Sigma \times P_\Gamma \Sigma : t(\gamma_i) = s(\gamma_j)\}$ of finitely many composable pairs of paths,
(iii) the composition $\circ : P_\Gamma \Sigma^2 \to P_\Gamma \Sigma$, where $(\gamma_i, \gamma_j) \mapsto \gamma_i \circ \gamma_j$,
(iv) the inversion map $\gamma_i \mapsto \gamma_i^{-1}$ of a path,
(v) the object inclusion map $\iota : V_\Gamma \to P_\Gamma \Sigma$ and
(vi) $P_\Gamma \Sigma$ is defined by the set $P_\Gamma \Sigma$ modulo the algebraic equivalence relations generated by

$$\gamma_i^{-1} \circ \gamma_i \simeq 1_{s(\gamma_i)} \text{ and } \gamma_i \circ \gamma_i^{-1} \simeq 1_{t(\gamma_i)}$$

(1)

Shorty write $P_\Gamma \Sigma \xrightarrow{\iota} V_\Gamma$.

Clearly, a graph $\Gamma$ generates freely the paths in $P_\Gamma \Sigma$. Moreover the map $s \times t : P_\Gamma \Sigma \to V_\Gamma \times V_\Gamma$ defined by $(s \times t)(\gamma) = (s(\gamma), t(\gamma))$ for all $\gamma \in P_\Gamma \Sigma$ is assumed to be surjective ($P_\Gamma \Sigma$ over $V_\Gamma$ is a transitive groupoid), too.

A general groupoid $G$ over $G^0$ defines a small category where the set of morphisms is denoted in general by $G$ and the set of objects is denoted by $G^0$. Hence in particular the path groupoid can be viewed as a category, since,

- the set of morphisms is identified with $P_\Gamma \Sigma$,
- the set of objects is given by $V_\Gamma$ (the units)
From the condition $[i]$ it follows that, the path groupoid satisfies additionally

(i) $s(\gamma_i \circ \gamma_j) = s(\gamma_i)$ and $t(\gamma_i \circ \gamma_j) = t(\gamma_j)$ for every $(\gamma_i, \gamma_j) \in \mathcal{P}_1^2 \Sigma$

(ii) $s(v) = v = t(v)$ for every $v \in V_1$

(iii) $\gamma \circ \mathbb{I}_{s(\gamma)} = \gamma = \mathbb{I}_{t(\gamma)} \circ \gamma$ for every $\gamma \in \mathcal{P}_1 \Sigma$ and

(iv) $\gamma \circ (\gamma_i \circ \gamma_j) = (\gamma \circ \gamma_i) \circ \gamma_j$

(v) $\gamma \circ (\gamma^{-1} \circ \gamma_1) = \gamma_1 = (\gamma_1 \circ \gamma) \circ \gamma^{-1}$

The condition $[i]$ implies that the vertices are units of the groupoid.

**Definition 2.3.** Denote the set of all finitely generated paths by

$$\mathcal{P}_1 \Sigma(n) := \{(\gamma_1, \ldots, \gamma_n) \in \mathcal{P}_1 \times \ldots \times \mathcal{P}_1 : (\gamma_i, \gamma_{i+1}) \in \mathcal{P}_1^{(2)}, 1 \leq i \leq n - 1\}$$

The set of paths with source point $v \in V_1$ is given by

$$\mathcal{P}_1 \Sigma^v := s^{-1}\{(v)\}$$

The set of paths with target point $v \in V_1$ is defined by

$$\mathcal{P}_1 \Sigma_v := t^{-1}\{(v)\}$$

The set of paths with source point $v \in V_1$ and target point $u \in V_1$ is

$$\mathcal{P}_1 \Sigma^v_u := \mathcal{P}_1 \Sigma^v \cap \mathcal{P}_1 \Sigma_u$$

A graph $\Gamma$ is said to be **disconnected** if it contains only mutually pairs $(\gamma_i, \gamma_j)$ of non-composable independent paths $\gamma_i$ and $\gamma_j$ for $i \neq j$ and $i, j = 1, \ldots, N$. In other words for all $1 \leq i, l \leq N$ it is true that $s(\gamma_i) \neq t(\gamma_l)$ and $t(\gamma_i) \neq s(\gamma_l)$ where $i \neq l$ and $\gamma_i, \gamma_l \in \Gamma$.

**Definition 2.4.** Let $\Gamma$ be a graph. A **subgraph** $\Gamma'$ of $\Gamma$ is given by a finite set of independent paths in $\mathcal{P}_1 \Sigma$.

For example let $\Gamma := \{\gamma_1, \ldots, \gamma_N\}$ then $\Gamma' := \{\gamma_1 \circ \gamma_2, \gamma_3^{-1}, \gamma_4\}$ where $\gamma_1 \circ \gamma_2, \gamma_3^{-1}, \gamma_4 \in \mathcal{P}_1 \Sigma$ is a subgraph of $\Gamma$, whereas the set $\{\gamma_1, \gamma_1 \circ \gamma_2\}$ is not a subgraph of $\Gamma$. Notice if additionally $(\gamma_2, \gamma_4) \in \mathcal{P}_1^{(2)}$ holds, then $\{\gamma_1, \gamma_3^{-1}, \gamma_2 \circ \gamma_4\}$ is a subgraph of $\Gamma$, too. Moreover for $\Gamma := \{\gamma\}$ the graph $\Gamma^{-1} := \{\gamma^{-1}\}$ is a subgraph of $\Gamma$. As well the graph $\Gamma$ is a subgraph of $\Gamma^{-1}$. A subgraph of $\Gamma$ that is generated by compositions of some paths, which are not reversed in their orientation, of the set $\{\gamma_1, \ldots, \gamma_N\}$ is called an **orientation preserved subgraph of a graph**. For example for $\Gamma := \{\gamma_1, \ldots, \gamma_N\}$ orientation preserved subgraphs are given by $\{\gamma_1 \circ \gamma_2\}, \{\gamma_1, \gamma_2, \gamma_N\}$ or $\{\gamma_N^{-2} \circ \gamma_{N-1}\}$ if $(\gamma_1, \gamma_2) \in \mathcal{P}_1 \Sigma^{(2)}$ and $(\gamma_N^{-2}, \gamma_{N-1}) \in \mathcal{P}_1 \Sigma^{(2)}$.

**Definition 2.5.** A **finite graph system** $\mathcal{P}_\Gamma$ for $\Gamma$ is a finite set of subgraphs of a graph $\Gamma$. A finite graph system $\mathcal{P}_\Gamma'$ for $\Gamma'$ is a **finite graph subsystem** of $\mathcal{P}_\Gamma$ for $\Gamma$ if the set $\mathcal{P}_\Gamma'$ is a subset of $\mathcal{P}_\Gamma$ and $\Gamma'$ is a subgraph of $\Gamma$. Shortly write $\mathcal{P}_\Gamma' \leq \mathcal{P}_\Gamma$.

A **finite orientation preserved graph system** $\mathcal{P}_\Gamma^o$ for $\Gamma$ is a finite set of orientation preserved subgraphs of a graph $\Gamma$.

Recall that, a finite path groupoid is constructed from a graph $\Gamma$, but a set of elements of the path groupoid need not be a graph again. For example let $\Gamma := \{\gamma_1 \circ \gamma_2\}$ and $\Gamma' = \{\gamma_1 \circ \gamma_3\}$, then $\Gamma'' = \Gamma \cup \Gamma'$ is not a graph, since this set is not independent. Hence appropriate unions of paths, which are elements of a fixed finite path groupoid, define graphs. The idea is to define a suitable action on elements of the path groupoid, which corresponds to an action of diffeomorphisms on the manifold $\Sigma$. The action has to be transferred to graph systems. But the action of bisection, which is defined by the use of the groupoid multiplication, cannot easily generalised for graph systems.

**Problem 2.1:** Let $\Gamma := \{\Gamma_i\}_{i=1, \ldots, N}$ be a finite set such that each $\Gamma_i$ is a set of not necessarily independent paths such that
(i) the set contains no loops and
(ii) each pair of paths satisfies one of the following conditions
   • the paths intersect each other only in one vertex,
   • the paths do not intersect each other or
   • one path of the pair is a segment of the other path.

Then there is a map \( \tilde{\Gamma} \times \tilde{\Gamma} \to \tilde{\Gamma} \) of two elements \( \Gamma_1 \) and \( \Gamma_2 \) defined by
\[
\{\gamma_1, ..., \gamma_M\} \circ \{\tilde{\gamma}_1, ..., \tilde{\gamma}_M\} := \left\{\gamma_i \circ \tilde{\gamma}_j : t(\gamma_i) = s(\tilde{\gamma}_j)\right\}_{1 \leq i,j \leq M}
\]
for \( \Gamma_1 := \{\gamma_1, ..., \gamma_M\}, \Gamma_2 := \{\tilde{\gamma}_1, ..., \tilde{\gamma}_M\} \). Moreover define a map \( \gamma^{-1} : \tilde{\Gamma} \to \tilde{\Gamma} \) by
\[
\{\gamma_1, ..., \gamma_M\}^{-1} := \{\gamma_1^{-1}, ..., \gamma_M^{-1}\}
\]
Then the following is derived
\[
\{\gamma_1, ..., \gamma_M\} \circ \{\gamma_1^{-1}, ..., \gamma_M^{-1}\} = \left\{\gamma_i \circ \gamma_j^{-1} : t(\gamma_i) = t(\gamma_j)\right\}_{1 \leq i,j \leq M}
\]
\[
\cup \{\{s_{\gamma_i}\}_{1 \leq j \leq M}
\]
\[
\neq \cup \{\{s_{\gamma_j}\}_{1 \leq j \leq M}
\]
The equality is true, if the set \( \tilde{\Gamma} \) contains only graphs such that all paths are mutually non-composable. Consequently this does not define a well-defined multiplication map. Notice that, the same is discovered if a similar map and inversion operation are defined for a finite graph system \( P_\Gamma \).

Consequently the property of paths being independent need not be dropped for the definition of a suitable multiplication and inversion operation. In fact the independence property is a necessary condition for the construction of the holonomy algebra for analytic paths. Only under this circumstance each analytic path is decomposed into a finite product of independent piecewise analytic paths again.

**Definition 2.6.** A finite path groupoid \( P_{\Gamma,\Sigma} \) over \( V_{\Gamma,\Sigma} \) is a finite path subgroupoid of \( P_{\Gamma,\Sigma} \) over \( V_{\Gamma} \) if the set \( V_{\Gamma,\Sigma} \) is contained in \( V_{\Gamma} \) and the set \( P_{\Gamma,\Sigma} \) is a subset of \( P_{\Gamma,\Sigma} \). Shorty write \( P_{\Gamma,\Sigma} \subseteq P_{\Gamma,\Sigma} \).

Clearly for a subgraph \( \Gamma_1 \) of a graph \( \Gamma_2 \), the associated path groupoid \( P_{\Gamma_1,\Sigma} \) over \( V_{\Gamma_1} \) is a subgroupoid of \( P_{\Gamma_2,\Sigma} \) over \( V_{\Gamma_2} \). This is a consequence of the fact that, each path in \( P_{\Gamma_1,\Sigma} \) is a composition of paths or their inverses in \( P_{\Gamma_2,\Sigma} \).

**Definition 2.7.** A family of finite path groupoids \( \{P_{\Gamma_i,\Sigma}\}_{i=1,\ldots,\infty} \), which is a set of finite path groupoids \( P_{\Gamma_i,\Sigma} \) over \( V_{\Gamma_i} \), is said to be inductive if for any \( P_{\Gamma_1,\Sigma}, P_{\Gamma_2,\Sigma} \exists \) exists a \( P_{\Gamma_3,\Sigma} \) such that \( P_{\Gamma_1,\Sigma}, P_{\Gamma_2,\Sigma} \leq P_{\Gamma_3,\Sigma} \).

A family of graph systems \( \{P_{\Gamma_i}\}_{i=1,\ldots,\infty} \), which is a set of finite path systems \( P_{\Gamma_i} \), is said to be inductive if for any \( P_{\Gamma_1}, P_{\Gamma_2} \exists \) exists a \( P_{\Gamma_3} \) such that \( P_{\Gamma_1}, P_{\Gamma_2} \leq P_{\Gamma_3} \).

**Definition 2.8.** Let \( \{P_{\Gamma_i,\Sigma}\}_{i=1,\ldots,\infty} \) be an inductive family of path groupoids and \( \{P_{\Gamma_i}\}_{i=1,\ldots,\infty} \) be an inductive family of graph systems.

The inductive limit path groupoid \( P \) over \( \Sigma \) of an inductive family of finite path groupoids such that \( P := \lim_{i \to \infty} P_{\Gamma_i,\Sigma} \) is called the (algebraic) path groupoid \( P \Rightarrow \Sigma \).

Moreover there exists an inductive limit graph \( \Gamma_\infty \) of an inductive family of graphs such that \( \Gamma_\infty := \lim_{i \to \infty} \Gamma_i \).

The inductive limit graph system \( P_{\Gamma,\infty} \) of an inductive family of graph systems such that \( P_{\Gamma,\infty} := \lim_{i \to \infty} P_{\Gamma_i} \).

Assume that, the inductive limit \( \Gamma_\infty \) of a inductive family of graphs is a graph, which consists of an infinite countable number of independent paths. The inductive limit \( P_{\Gamma,\infty} \) of a inductive family \( \{P_{\Gamma_i}\} \) of finite graph systems contains an infinite countable number of subgraphs of \( \Gamma_\infty \) and each subgraph is a finite set of arbitrary independent paths in \( \Sigma \).
2.2 Holonomy maps for finite path groupoids, graph systems and transformations

In section 2.1 the concept of finite path groupoids for analytic paths has been given. Now the holonomy maps are introduced for finite path groupoids and finite graph systems. The ideas are familiar with those presented by Thiemann [17]. But for example the finite graph systems have not been studied before. Ashtekar and Lewandowski [1] have defined the analytic holonomy $C^*$-algebra, which they have based on a finite set of independent hoops. The hoops are generalised for path groupoids and the independence requirement is implemented by the concept of finite graph systems.

2.2.1 Holonomy maps for finite path groupoids

Let $G_1 \xrightarrow{s_1} G_0^1 \xleftarrow{t_1} G_2$, $G_2 \xrightarrow{s_2} G_0^2 \xleftarrow{t_2}$ be two arbitrary groupoids.

Definition 2.9. A groupoid morphism between two groupoids $G_1$ and $G_2$ consists of two maps $h : G_1 \rightarrow G_2$ and $s : G_0^1 \rightarrow G_0^2$ such that

1. $h(\gamma \circ \gamma') = h(\gamma)h(\gamma')$ for all $(\gamma, \gamma') \in G_1^{(2)}$
2. $s_2(h(\gamma)) = h(s_1(\gamma)), \ t_2(h(\gamma)) = h(t_1(\gamma))$

A strong groupoid morphism between two groupoids $G_1$ and $G_2$ additionally satisfies

3. for every pair $(h(\gamma), h(\gamma')) \in G_2^{(2)}$ it follows that $(\gamma, \gamma') \in G_1^{(2)}$

Let $G$ be a Lie group. Then $G$ over $e_G$ is a groupoid, where the group multiplication $\cdot : G^2 \rightarrow G$ is defined for all elements $g_1, g_2, g \in G$ such that $g_1 \cdot g_2 = g$. A groupoid morphism between a finite path groupoid $P_\Sigma \rightarrow G$ is given by the maps

$h : P_\Sigma \rightarrow G, \ h : V_\Sigma \rightarrow e_G$

Clearly

$h(\gamma \circ \gamma') = h(\gamma)h(\gamma')$ for all $(\gamma, \gamma') \in P_\Sigma^{(2)}$

$s_G(h(\gamma)) = h(s_\Sigma(\gamma)), \ t_G(h(\gamma)) = h(t_\Sigma(\gamma))$ (2)

But for an arbitrary pair $(h_1(\gamma_1), h_2(\gamma_2)) = (g_1, g_2) \in G^{(2)}$ it does not follows that, $(\gamma_1, \gamma_2) \in P_\Sigma^{(2)}$ is true. Hence $h_\Sigma$ is not a strong groupoid morphism.

Definition 2.10. Let $P_\Sigma \Rightarrow V_\Gamma$ be a finite path groupoid.

Two paths $\gamma$ and $\gamma'$ in $P_\Sigma$ have the same-holonomy for all connections iff

$h(\gamma) = h(\gamma')$ for all $(h, h')$ groupoid morphisms

$h : P_\Sigma \rightarrow G, \ h : V_\Sigma \rightarrow e_G$

Denote the relation by $\sim_{s, \text{hol}}$.

Lemma 2.11. The same-holonomy for all connections relation is an equivalence relation.

Notice that, the quotient of the finite path groupoid and the same-holonomy relation for all connections replace the hoop group, which has been used in [1].

Definition 2.12. Let $P_\Sigma \Rightarrow V_\Gamma$ be a finite path groupoid modulo same-holonomy for all connections equivalence.

A holonomy map for a finite path groupoid $P_\Sigma \rightarrow V_\Gamma$ is a groupoid morphism consisting of the maps $(h_\Sigma, h_\Gamma)$, where $h_\Sigma : P_\Sigma \rightarrow G, h_\Gamma : V_\Gamma \rightarrow \{e_G\}$. The set of all holonomy maps is abbreviated by $\text{Hom}(P_\Sigma, G)$.

For a short notation observe the following. In further sections it is always assumed that, the finite path groupoid $P_\Sigma \Rightarrow V_\Gamma$ is considered modulo same-holonomy for all connections equivalence although it is not stated explicitly.
2.2.2 Holonomy maps for finite graph systems

Ashtekar and Lewandowski [1] have presented the loop decomposition into a finite set of independent hoops (in the analytic category). This structure is replaced by a graph, since a graph is a set of independent edges. Notice that, the set of hoops that is generated by a finite set of independent hoops, is generalised to the set of finite graph systems. A finite path groupoid is generated by the set of edges, which defines a graph $\Gamma$, but a set of elements of the path groupoid need not be a graph again. The appropriate notion for graphs constructed from sets of paths is the finite graph system, which is defined in section [2]. Now the concept of holonomy maps is generalised for finite graph systems. Since the set, which is generated by a finite number of independent edges, contains paths that are composable, there are two possibilities to identify the image of the holonomy map for a finite graph system on a fixed graph with a subgroup of $G^{[1]}$. One way is to use the generating set of independent edges of a graph, which has been also used in [1]. On the other hand, it is also possible to identify each graph with a disconnected subgraph of a fixed graph, which is generated by a set of independent edges. Notice that, the author implements two situations. One case is given by a set of paths that can be composed further and the other case is related to paths that are not composable. This is necessary for the definition of an action of the flux operators. Precisely the identification of the image of the holonomy maps along these paths is necessary to define a well-defined action of a flux element on the configuration space [3].

First of all consider a graph $\Gamma$ that is generated by the set $\{\gamma_1, \ldots, \gamma_N\}$ of edges. Then each subgraph of a graph $\Gamma$ contains paths that are composition of edges in $\{\gamma_1, \ldots, \gamma_N\}$ or inverse edges. For example the following set $\Gamma' := \{\gamma_1 \circ \gamma_2 \circ \gamma_3, \gamma_4\}$ defines a subgraph of $\Gamma := \{\gamma_1, \gamma_2, \gamma_3, \gamma_4\}$. Hence there is a natural identification available.

Definition 2.13. A subgraph $\Gamma'$ of a graph $\Gamma$ is always generated by a subset $\{\gamma_{1}, \ldots, \gamma_{M}\}$ of the generating set $\{\gamma_{1}, \ldots, \gamma_{N}\}$ of independent edges that generates the graph $\Gamma$. Hence each subgraph is identified with a subset of $\{\gamma_{1}^{-1}, \ldots, \gamma_{N}^{-1}\}$. This is called the natural identification of subgraphs.

Example 2.1: For example consider a subgraph $\Gamma' := \{\gamma_1 \circ \gamma_2, \gamma_3 \circ \gamma_4, \ldots, \gamma_{M-1} \circ \gamma_{M}\}$, which is identified naturally with a set $\{\gamma_1, \ldots, \gamma_M\}$. The set $\{\gamma_1, \ldots, \gamma_M\}$ is a subset of $\{\gamma_1, \ldots, \gamma_N\}$ where $N = |\Gamma|$ and $M \leq N$. Another example is given by the graph $\Gamma'' := \{\gamma_1, \gamma_2\}$ such that $\gamma_2 = \gamma_1' \circ \gamma_2'$, then $\Gamma''$ is identified naturally with $\{\gamma_1, \gamma_1', \gamma_2, \gamma_2'\}$. This is a subset of $\{\gamma_1, \gamma'_1, \gamma_2, \gamma_3, \ldots, \gamma_N\}$.

Definition 2.14. Let $\Gamma$ be a graph, $P_{\Gamma}$ be the finite graph system. Let $\Gamma' := \{\gamma_{1}, \ldots, \gamma_{M}\}$ be a subgraph of $\Gamma$.

A holonomy map for a finite graph system $P_{\Gamma}$ is given by a pair of maps $(h_{\Gamma}, h_{\Gamma'})$ such that there exists a holonomy map $^{[1]}(h_{\Gamma}, h_{\Gamma'})$ for the finite path groupoid $P_{\Sigma} \rightrightarrows V_{\Gamma}$ and

$$ h_{\Gamma} : P_{\Gamma} \rightarrow G^{[1]}, \quad h_{\Gamma'}(\{\gamma_{1}, \ldots, \gamma_{M}\}) = (h_{\Gamma}(\gamma_1), \ldots, h_{\Gamma}(\gamma_M), e_G, \ldots, e_G) $$

$$ h_{\Gamma'} : V_{\Gamma} \rightarrow \{e_G\} $$

The set of all holonomy maps for the finite graph system is denoted by $\text{Hom}(P_{\Gamma}, G^{[1]})$.

The image of a map $h_{\Gamma}$ on each subgraph $\Gamma'$ of the graph $\Gamma$ is given by

$$ (h_{\Gamma}(\gamma_1), \ldots, h_{\Gamma}(\gamma_M), e_G, \ldots, e_G) $$

is an element of $G^{[1]}$. The set of all images of maps on subgraphs of $\Gamma$ is denoted by $\bar{A}_{\Gamma}$.

The idea is now to study two different restrictions of the set $P_{\Gamma}$ of subgraphs. For a short notation of a "set of holonomy maps for a certain restricted set of subgraphs of a graph" in this article the following notions are introduced.

Definition 2.15. If the subset of all disconnected subgraphs of the finite graph system $P_{\Gamma}$ is considered, then the restriction of $\bar{A}_{\Gamma}$, which is identified with $G^{[1]}$, appropriately, is called the non-standard identification of the configuration space. If the subset of all natural identified subgraphs of the finite graph system $P_{\Gamma}$ is considered, then the restriction of $\bar{A}_{\Gamma}$, which is identified with $G^{[1]}$, appropriately, is called the natural identification of the configuration space.

---

\(^{[1]}\)In the work the holonomy map for a finite graph system and the holonomy map for a finite path groupoid is denoted by the same pair $(h_{\Gamma}, h_{\Gamma'})$. 

---

8
A comment on the non-standard identification of \( A_\Gamma \) is the following. If \( \Gamma' := \{ \gamma_1 \circ \gamma_2 \} \) and \( \Gamma'' := \{ \gamma_2 \} \) are two subgraphs of \( \Gamma := \{ \gamma_1, \gamma_2, \gamma_3 \} \). The graph \( \Gamma' \) is a subgraph of \( \Gamma \). Then evaluation of a map \( h_\Gamma \) on a subgraph \( \Gamma' \) is given by

\[
h_\Gamma(\Gamma') = (h_\Gamma(\gamma_1 \circ \gamma_2), h_\Gamma(s(\gamma_2)), h_\Gamma(s(\gamma_3))) = (h_\Gamma(\gamma_1), h_\Gamma(\gamma_2), e_G, e_G) \in G^3
\]

and the holonomy map of the subgraph \( \Gamma'' \) of \( \Gamma' \) is evaluated by

\[
h_\Gamma(\Gamma'') = (h_\Gamma(s(\gamma_1)), h_\Gamma(s(\gamma_2)), h_\Gamma(e_G), e_G) \in G^3
\]

**Example 2.2:** Recall example 2.2.1. For example for a subgraph \( \Gamma' := \{ \gamma_1 \circ \gamma_2 \circ \gamma_3, \gamma_4, \ldots, \gamma_{M-1} \circ \gamma_M \} \), which is naturally identified with a set \( \{ \gamma_1, \ldots, \gamma_M \} \). Then the holonomy map is evaluated at \( \Gamma' \) such that

\[
h_\Gamma(\Gamma') = (h_\Gamma(\gamma_1), h_\Gamma(\gamma_2), \ldots, h_\Gamma(\gamma_M), e_G, \ldots, e_G) \in G^N
\]

where \( N = |\Gamma| \). For example, let \( \Gamma' := \{ \gamma_1, \gamma_2 \} \) such that \( \gamma_2 = \gamma_1' \circ \gamma_2' \) and which is naturally identified with \( \{ \gamma_1, \gamma_1', \gamma_2' \} \). Hence

\[
h_\Gamma(\Gamma') = (h_\Gamma(\gamma_1), h_\Gamma(\gamma_1'), h_\Gamma(\gamma_2'), e_G, \ldots, e_G) \in G^N
\]

is true.

Another example is given by the disconnected graph \( \Gamma'' := \{ \gamma_1 \circ \gamma_2 \circ \gamma_3, \gamma_4 \} \), which is a subgraph of \( \Gamma := \{ \gamma_1, \gamma_2, \gamma_3, \gamma_4 \} \). Then the non-standard identification is given by

\[
h_\Gamma(\Gamma'') = (h_\Gamma(\gamma_1 \circ \gamma_2 \circ \gamma_3), h_\Gamma(\gamma_4), e_G, e_G) \in G^4
\]

If the natural identification is used, then \( h_\Gamma(\Gamma'') \) is identified with

\[
(h_\Gamma(\gamma_1), h_\Gamma(\gamma_2), h_\Gamma(\gamma_3), h_\Gamma(\gamma_4)) \in G^4
\]

Consider the following example. Let \( \Gamma''' := \{ \gamma_1, \alpha, \gamma_2, \gamma_3 \} \) be a graph such that

\[
\begin{array}{c}
\gamma_1 \\
\alpha \\
\gamma_2 \\
\gamma_3
\end{array}
\]

Then notice the sets \( \Gamma_1 := \{ \gamma_1 \circ \alpha, \gamma_3 \} \) and \( \Gamma_2 := \{ \gamma_1 \circ \alpha^{-1}, \gamma_3 \} \). In the non-standard identification of the configuration space \( \bar{\mathcal{A}}_{\Gamma} \), it is true that,

\[
h_{\Gamma'''}(\Gamma_1) = (h_{\Gamma'''}(\gamma_1 \circ \alpha), h_{\Gamma'''}(\gamma_3), e_G, e_G) \in G^4,
\]

\[
h_{\Gamma'''}(\Gamma_2) = (h_{\Gamma'''}(\gamma_1 \circ \alpha^{-1}), h_{\Gamma'''}(\gamma_3), e_G, e_G) \in G^4
\]

holds. Whereas in the natural identification of \( \bar{\mathcal{A}}_{\Gamma} \)

\[
h_{\Gamma'''}(\Gamma_1) = (h_{\Gamma'''}(\gamma_1), h_{\Gamma'''}(\alpha), h_{\Gamma'''}(\gamma_3), e_G) \in G^4,
\]

\[
h_{\Gamma'''}(\Gamma_2) = (h_{\Gamma'''}(\gamma_1), h_{\Gamma'''}(\alpha^{-1}), h_{\Gamma'''}(\gamma_3), e_G) \in G^4
\]

yields.

The equivalence class of similar or equivalent groupoid morphisms defined in definition ?? allows to define the following object. The set of images of all holonomy maps of a finite graph system modulo the similar or equivalent groupoid morphisms equivalence relation is denoted by \( \bar{\mathcal{A}}_{\Gamma}/\bar{\mathcal{G}}_{\Gamma} \).
2.2.3 Transformations in finite path groupoids and finite graph systems

The aim of this section is to clarify the graph changing operators in LQG framework and the role of finite diffeomorphisms in $\Sigma$. Therefore operations, which add, delete or transform paths, are introduced. In particular translations in a finite path graph groupoid and in the groupoid $G$ over \{e_G\} are studied.

Transformations in finite path groupoid

**Definition 2.16.** Let $\varphi$ be a $C^k$-diffeomorphism on $\Sigma$, which maps surfaces into surfaces.

Then let $(\Phi_T, \varphi_T)$ be a pair of bijective maps, where $\varphi|_{V_T} = \varphi_T$ and

\[
\Phi_T : \mathcal{P}_T \Sigma \to \mathcal{P}_T \Sigma \quad \text{and} \quad \varphi_T : V_T \to V_T
\]

such that

\[
(s \circ \Phi_T)(\gamma) = (\varphi_T \circ s)(\gamma), \quad (t \circ \Phi_T)(\gamma) = (\varphi_T \circ t)(\gamma)
\]

for all $\gamma \in \mathcal{P}_T \Sigma$ holds such that $(\Phi_T, \varphi_T)$ defines a groupoid morphism.

Call the pair $(\Phi_T, \varphi_T)$ a path-diffeomorphism of a finite path groupoid $\mathcal{P}_T \Sigma$ over $V_T$. Denote the set of finite path-diffeomorphisms by $\text{Diff}(\mathcal{P}_T \Sigma)$.

Notice that, for $(\gamma, \gamma') \in \mathcal{P}_T \Sigma^{(2)}$ it is true that

\[
\Phi_T(\gamma \circ \gamma') = \Phi_T(\gamma) \circ \Phi_T(\gamma')
\]

requires that

\[
(t \circ \Phi_T)(\gamma) = (s \circ \Phi_T)(\gamma')
\]

Hence from (3) and (5) it follows that, $\Phi_T(\mathbb{I}_v) = \mathbb{I}_{\varphi_T(v)}$ is true.

A path-diffeomorphism $(\Phi_T, \varphi_T)$ is lifted to $\text{Hom}(\mathcal{P}_T \Sigma, G)$.

The pair $(h_T \circ \Phi_T, h_T \circ \varphi_T)$ defined by

\[
\begin{align*}
    h_T \circ \Phi_T &: \mathcal{P}_T \Sigma \to G, \quad \gamma \mapsto (h_T \circ \Phi_T)(\gamma) \\
    h_T \circ \varphi_T &: V_T \to \{e_G\}, \quad (h_T \circ \varphi_T)(v) = e_G
\end{align*}
\]

such that

\[
s_{\text{Hol}}((h_T \circ \Phi_T)(\gamma)) = (h_T \circ \varphi_T)(s(\gamma)) = e_G,
\]

\[
 t_{\text{Hol}}((h_T \circ \Phi_T)(\gamma)) = (h_T \circ \varphi_T)(t(\gamma)) = e_G
\]

for all $\gamma \in \mathcal{P}_T \Sigma$ whenever $(h_T, h_T) \in \text{Hom}(\mathcal{P}_T \Sigma, G)$ and $(\Phi_T, \varphi_T)$ is a path-diffeomorphism, is a holonomy map for a finite path groupoid $\mathcal{P}_T \Sigma$ over $V_T$.

**Definition 2.17.** A left-translation in the finite path groupoid $\mathcal{P}_T \Sigma$ over $V_T$ at a vertex $v$ is a map defined by

\[
L_\theta : \mathcal{P}_T \Sigma^v \to \mathcal{P}_T \Sigma^w, \quad \gamma \mapsto L_\theta(\gamma) := \theta \circ \gamma
\]

for some $\theta \in \mathcal{P}_T \Sigma^w$ and all $\gamma \in \mathcal{P}_T \Sigma^v$.

In analogy a right-translation $R_\theta$ and an inner-translation $I_{\theta\theta'}$ in the finite path groupoid $\mathcal{P}_T \Sigma$ over $V_T$ at a vertex $v$ can be defined.

**Remark 2.18.** Let $(\Phi_T, \varphi_T)$ be a path-diffeomorphism on a finite path groupoid $\mathcal{P}_T \Sigma$ over $V_T$. Then a left-translation in the finite path groupoid $\mathcal{P}_T \Sigma$ over $V_T$ at a vertex $v$ is defined by a path-diffeomorphism $(\Phi_T, \varphi_T)$ and the following object

\[
L_{\Phi_T} : \mathcal{P}_T \Sigma^v \to \mathcal{P}_T \Sigma^{v_{\varphi_T}(v)}, \quad \gamma \mapsto L_{\Phi_T}(\gamma) := \Phi_T(\gamma) \quad \text{for} \quad \gamma \in \mathcal{P}_T \Sigma^v
\]
Furthermore a right-translation in the finite path groupoid \( \mathcal{P}_T \Sigma \) over \( V_T \) at a vertex \( v \) is defined by a path-diffeomorphism \((\Phi_T, \varphi_T)\) and the following object

\[
R_{\Phi_T} : \mathcal{P}_T \Sigma_v \rightarrow \mathcal{P}_T \Sigma_{\varphi_T(v)}, \quad \gamma \mapsto R_{\Phi_T}(\gamma) := \Phi_T(\gamma) \text{ for } \gamma \in \mathcal{P}_T \Sigma_v
\]

Finally an inner-translation in the finite path groupoid \( \mathcal{P}_T \Sigma \) over \( V_T \) at the vertices \( v \) and \( w \) is defined by

\[
I_{\Phi_T} : \mathcal{P}_T \Sigma_w^v \rightarrow \mathcal{P}_T \Sigma_{\varphi_T(v)}^{\varphi_T(w)}, \quad \gamma \mapsto I_{\Phi_T}(\gamma) = \Phi_T(\gamma) \text{ for } \gamma \in \mathcal{P}_T \Sigma_w^v
\]

where \((s \circ \Phi_T)(\gamma) = \varphi_T(v)\) and \((t \circ \Phi_T)(\gamma) = \varphi_T(w)\).

In the following considerations the right-translation in a finite path groupoid is focused, but there is a generalisation to left-translations and inner-translations.

**Definition 2.19.** A bisection of a finite path groupoid \( \mathcal{P}_T \Sigma \) over \( V_T \) is a map \( \sigma : V_T \rightarrow \mathcal{P}_T \Sigma \), which is right-inverse to the map \( s : \mathcal{P}_T \Sigma \rightarrow V_T \) (i.o.w. \( s \circ \sigma = \text{id}_{V_T} \)) and such that \( t \circ \sigma : V_T \rightarrow V_T \) is a bijective map. The set of bisections on \( \mathcal{P}_T \Sigma \) over \( V_T \) is denoted \( \mathcal{B}(\mathcal{P}_T \Sigma) \).

**Remark 2.20.** Discover that, a bisection \( \sigma \in \mathcal{B}(\mathcal{P}_T \Sigma) \) defines a path-diffeomorphism \((\varphi_T, \Phi_T) \in \text{Diff}(\mathcal{P}_T \Sigma)\), where \( \varphi_T = t \circ \sigma \) and \( \Phi_T \) is given by the right-translation \( R_{\sigma(v)} : \mathcal{P}_T \Sigma_v \rightarrow \mathcal{P}_T \Sigma_{\varphi_T(v)} \) in \( \mathcal{P}_T \Sigma \cong V_T \), where \( R_{\sigma(v)}(\gamma) = \Phi_T(\gamma) \) for all \( \gamma \in \mathcal{P}_T \Sigma_v \) and for a fixed \( v \in V_T \). The right-translation is defined by

\[
R_{\sigma(v)}(\gamma) := \begin{cases} 
\gamma \circ \sigma(v) & v = t(\gamma) \\
\gamma \circ \mathbb{1}_{t(\gamma)} & v \neq t(\gamma)
\end{cases}
\]

whenever \( t(\gamma) \) is the target vertex of a non-trivial path \( \gamma \) in \( \Gamma \). For a trivial path \( \mathbb{1}_v \) the right-translation is defined by \( R_{\sigma(v)}(\mathbb{1}_v) = \mathbb{1}_{(t \circ \sigma)(v)} \) and \( R_{\sigma(v)}(\mathbb{1}_w) = \mathbb{1}_w \) whenever \( v \neq w \). The right-translation \( R_{\sigma(v)} \) is required to be bijective. Before this result is proven in lemma 2.23 notice the following considerations.

Note that, \((R_{\sigma(v)}, t \circ \sigma)\) transfers to the holonomy map such that

\[
(h_T \circ R_{\sigma(t(\gamma'))}(\gamma \circ \gamma')) = h_T((\gamma \circ (t \circ \sigma(t(\gamma'))))) = h_T((\gamma) \circ h_T((\gamma' \circ \sigma(t(\gamma'))))
\]

is true. There is a bijective map between a right-translation \( R_{\sigma(v)} : \mathcal{P}_T \Sigma_v \rightarrow \mathcal{P}_T \Sigma_{(t \circ \sigma)(v)} \) and a path-diffeomorphism \((\varphi_T, \Phi_T)\). In particular observe that, \( \sigma \in \mathcal{B}(\mathcal{P}_T \Sigma_v) \) and \((\varphi_T, \Phi_T) \in \text{Diff}(\mathcal{P}_T \Sigma_v)\). Simply speaking the path-diffeomorphism does not change the source and target vertex at the same time. The path-diffeomorphism changes the target vertex by a (finite) diffeomorphism and, therefore, the path is transformed.

Bisections \( \sigma \) in a finite path groupoid can be transferred, likewise path-diffeomorphisms, to holonomy maps. The pair \((h_T \circ \Phi_T, h_T \circ \varphi_T)\) of the maps defines a pair of maps \((h_T \circ \Phi_T, h_T \circ \varphi_T)\) by

\[
h_T \circ \Phi_T : \mathcal{P}_T \Sigma_w \rightarrow G \text{ and } h_T \circ \varphi_T : V_T \rightarrow \{e_G\}
\]

which is a holonomy map for a finite path groupoid \( \mathcal{P}_T \Sigma \) over \( V_T \).

**Lemma 2.21.** The set \( \mathcal{B}(\mathcal{P}_T \Sigma) \) of bisections on the finite path groupoid \( \mathcal{P}_T \Sigma \) over \( V_T \) forms a group.

**Proof :** The group multiplication is given by

\[
(\sigma \ast \sigma')(v) = \sigma'(v) \circ \sigma(t(\sigma'(v))) \text{ for } v \in V_T
\]

whenever \( \sigma'(v) \in \mathcal{P}_T \Sigma_{t(\sigma'(v))}^{t(\sigma'(v))} \) and \( \sigma(t(\sigma'(v))) \in \mathcal{P}_T \Sigma_{(t \circ \sigma')(v)}^{(t \circ \sigma')(v)} \).

Clearly the group multiplication is associative. The unit id is equivalent to the object inclusion \( v \mapsto \mathbb{1}_v \) of the groupoid \( \mathcal{P}_T \Sigma \cong V_T \), where \( \mathbb{1}_v \) is the constant loop at \( v \), and the inversion is given by

\[
\sigma^{-1}(v) = \sigma((t \circ \sigma)^{-1}(v))^{-1} \text{ for } v \in V_T
\]

---

\(^2\text{Note that in the infinite case of path groupoids an additional condition for the map } t \circ \sigma : \Sigma \rightarrow \Sigma \text{ has to be required. The map has to be a diffeomorphism. Observe that, the map } t \circ \sigma \text{ defines the finite diffeomorphism } \varphi_T : V_T \rightarrow V_T.\)
The group property of bisections $\mathcal{B}(\mathcal{P}T\Sigma)$ carries over to holonomy maps. Using the group multiplication of $\mathcal{G}$ conclude that

$$(h_T \circ R_{(\sigma \circ \gamma')((v))}(1_T)) = h_T \circ (R_{\sigma'(v)} \circ R_{t(\sigma'(v)))}(1_T)) = h_T(\sigma'(v)) \cdot h_T(\sigma'(t(\sigma'(v))))$$ for $v \in V_T$

is true.

**Remark 2.22.** Moreover right-translations define path-diffeomorphisms, i.e. $R_{(\sigma)(v)} = \Phi_T$ and $\varphi_T = t \circ \sigma$ whenever $v \in V_T$. But for two bisections $\sigma_T, \delta_T \in \mathcal{B}(\mathcal{P}T\Sigma)$ the object $\sigma_T(v) \circ \delta_T(v)$ is not comparable with $(\sigma_T \circ \delta_T)(v)$. Then for the composition $\Phi_T(\gamma) \circ \Phi_T(\gamma)$, there exists no path-diffeomorphism $\Phi$ such that $\Phi_T(\gamma) \circ \Phi_T(\gamma) = \Phi(\gamma)$ yields in general. Moreover generally the object $\Phi_T(\gamma) \circ \Phi_T(\gamma') = \Phi(\gamma \circ \gamma')$ is not well-defined.

*But the following is defined*

$$R_{(\sigma \circ \gamma')(v)}(\gamma) = \Phi_T(\gamma) \circ \Phi_T(1_{\nu(v)}) =: (\Phi_T \circ \Phi_T)(\gamma)$$

whenever $\gamma \in \mathcal{P}T\Sigma_v$, $(\varphi_T, \Phi_T) \in \text{Diff}(\mathcal{P}T\Sigma_v)$ and $(\varphi_T', \Phi_T') \in \text{Diff}(\mathcal{P}T\Sigma_{\nu(v)})$ are path-diffeomorphisms such that $\varphi_T = t \circ \sigma$, $\Phi_T = R_{\sigma(\nu(v))}$ and $\varphi_T' = t \circ \sigma'$, $\Phi_T' = R_{\sigma'(v)}$.

Moreover for $(\gamma, \gamma') \in \mathcal{P}T\Sigma_{(2)}$ and $\gamma' \in \mathcal{P}T\Sigma_v$ it is true that

$$(\Phi_T' \circ \Phi_T)(\gamma \circ \gamma') = \Phi_T'(\gamma \circ \gamma') \circ \Phi_T(1_{\nu(v)}) = \Phi_T'(\gamma) \circ \Phi_T(1_{\nu(v)}) = \Phi_T(\gamma) \circ (\Phi_T' \circ \Phi_T)(\gamma')$$

holds.

Then the following lemma easily follows.

**Lemma 2.23.** Let $\sigma$ be a bisection contained in $\mathcal{B}(\mathcal{P}T\Sigma)$ and $v \in V_T$.

The pair $(R_{\sigma(v)}, t \circ \sigma)$ of maps such that

$$R_{\sigma(v)}: \mathcal{P}T\Sigma_v \to \mathcal{P}T\Sigma_{(t \circ \sigma)(v)}; \quad s \circ R_{\sigma(v)} = (t \circ \sigma) \circ s$$

$$t \circ \sigma: V_T \to V_T; \quad t \circ R_{\sigma(v)} = (t \circ \sigma) \circ t$$

defined in remark 2.20 is a path-diffeomorphism in $\mathcal{P}T\Sigma \otimes V_T$.

**Proof:** This follows easily from the derivation

$$R_{\sigma(t(v))}(\gamma \circ \gamma') = \gamma \circ \gamma' \circ \sigma(t(v)) = R_{\sigma(t(v))}(\gamma) \circ R_{\sigma(t(v))}(\gamma')$$

$$R_{\sigma(t(v))}(1_{\nu(v)} \circ \gamma) = R_{\sigma(t(v))}(1_{\nu(v)}) \circ R_{\sigma(t(v))}(\gamma) = 1_{\nu(v)} \circ \sigma(t(v))$$

The inverse map satisfies

$$R_{\sigma(v)}^{-1}(\gamma \circ \sigma(v)) = R_{\sigma^{-1}(v)}(\gamma \circ \sigma(v)) = \gamma \circ \sigma(v) \circ \sigma^{-1}(v) = \gamma$$

whenever $v = t(v)$,

$$R_{\sigma(v)}^{-1}(\gamma) = \gamma$$

whenever $v \neq t(v)$ and

$$R_{\sigma(v)}^{-1}(1_{(t \circ \sigma)(v)}) = 1_v$$

Moreover derive

$$(s \circ R_{\sigma(v)})(\gamma') = ((t \circ \sigma) \circ s)(\gamma')$$

for all $\gamma' \in \mathcal{P}T\Sigma_v$ and a fixed bisection $\sigma \in \mathcal{B}(\mathcal{P}T\Sigma)$.

\[\blacksquare\]
Notice that, $L_{σ(v)}$ and $R_{σ(v)}$ similarly to the pair $(R_{σ(v)}, t \circ σ)$ can be defined. Summarising the pairs $(R_{σ(v)}, t \circ σ), (L_{σ(v)}, t \circ σ)$ and $(I_{σ(v)}, t \circ σ)$ for a bisection $σ ∈ Β(ΠΓΣ)$ are path-diffeomorphisms of a finite path groupoid $ΠΓΣ \rightrightarrows VΓ$. In general a right-translation $(R_σ, t \circ σ)$ in the finite path groupoid $ΠΓΣ$ over $Σ$ for a bisection $σ ∈ Β(ΠΓΣ)$ is defined by the bijective maps $R_σ$ and $t \circ σ$, which are given by

\[
R_σ : ΠΓΣ \rightarrow ΠΓΣ, \quad s \circ R_σ = s, \quad t \circ σ : VΓ \rightarrow VΓ, \quad t \circ R_σ = (t \circ σ) \circ t
\]

For example for a fixed suitable bisection $σ$ the right-translation is $R_σ(1_v) = γ$, then $R_σ^{-1}(γ) = γ \circ γ^{-1} = 1_v$ for $v = s(γ)$. Clearly the right-translation $(R_σ, t \circ σ)$ is not a groupoid morphism in general.

**Definition 2.24.** Define for a given bisection $σ$ in $Β(ΠΓΣ)$, the **right-translation in the groupoid $G$ over $\{e_G\}$** through

\[
hΓ \circ R_σ : ΠΓΣ \rightarrow G, \quad γ \mapsto (hΓ \circ R_σ)(γ) := hΓ(γ \circ σ(γ)) = hΓ(γ) \cdot hΓ(σ(γ))
\]

Furthermore for a fixed $σ ∈ Β(ΠΓΣ)$ define the **left-translation in the groupoid $G$ over $\{e_G\}$** by

\[
hΓ \circ L_σ : ΠΓΣ \rightarrow G, \quad γ \mapsto hΓ(σ((t \circ σ)^{-1}(s(γ))) \circ γ) = hΓ(σ((t \circ σ)^{-1}(s(γ)))) \cdot hΓ(γ)
\]

and the **inner-translation in the groupoid $G$ over $\{e_G\}$**

\[
hΓ \circ I_σ : ΠΓΣ \rightarrow G, \quad γ \mapsto hΓ(σ((t \circ σ)^{-1}(s(γ))) \circ γ \circ σ(γ)) = hΓ(σ((t \circ σ)^{-1}(s(γ)))) \cdot hΓ(γ) \cdot hΓ(σ(γ))
\]

such that $I_σ = L_{σ^{-1}} \circ R_σ$.

The pairs $(R_σ, t \circ σ)$ and $(L_σ, t \circ σ)$ are not groupoid morphisms. Whereas the pair $(I_σ, t \circ σ)$ is a groupoid morphism, since for all pairs $(γ, γ') ∈ ΠΓΣ^{(2)}$ such that $t(γ) = s(γ')$ it is true that $σ(t(γ)) \circ σ((t \circ σ)^{-1}(t(γ)))^{-1} = 1_{Γ(γ)}$ holds. Notice that, in this situation $σ(t(γ)) = σ(t(γ') \circ γ^{-1})$ is satisfied.

**Proposition 2.25.** The map $σ \mapsto R_σ$ is a group isomorphism, i.e. $R_{σσ'} = R_σ \circ R_{σ'}$ and where $σ \mapsto t \circ σ$ is a group isomorphism from $Β(ΠΓΣ)$ to the group of finite diffeomorphisms $Diff(VΓ)$ in a finite subset $VΓ$ of $Σ$.

The maps $σ \mapsto L_σ$ and $σ \mapsto I_σ$ are group isomorphisms.

There is a generalisation of path-diffeomorphisms in the finite path groupoid, which coincide with the graphomorphism presented by Fleischhack in [5]. In this approach the diffeomorphism $φ : Σ \rightarrow Σ$ changes the source and target vertex of a path $γ$. Consequently the path-diffeomorphism $(φ, φ)$, which implements the inner-translation $I_φ$ in the path groupoid $ΠΣ \rightrightarrows Σ$, is a graphomorphism in the context of Fleischhack. Some element of the set of graphomorphisms is directly related to a right-translation $R_φ$ in the path groupoid. Precisely for every $v ∈ Σ$ and $σ ∈ Β(ΠΣ)$ the pairs $(R_{φ(v)}, t \circ σ), (L_{φ(v)}, t \circ σ)$ and $(I_{φ(v)}, t \circ σ)$ define graphomorphism. Furthermore the right-translation $R_{φ(v)}$, the left-translation $L_{φ(v)}$ and the inner-translation $I_{φ(v)}$ are required to be bijective maps, and hence the maps cannot map non-trivial paths to trivial paths. This property restricts the set of all graphomorphisms, which is generated by these translations. In particular in this article graph changing operations, which change the number of edges of a graph, are studied. Hence the left- or right-translation in a finite path groupoid is used in the further development. Notice that in general, these objects do not define graphomorphism. Finally notice that, in particular for the graphomorphism $(R_{φ(v)}, t \circ σ)$ and a holonomy map for the path groupoid $ΠΣ \rightrightarrows Σ$ a similar relation holds. The last equation is fundamental for the construction of $C^*$-dynamical systems, which contain the analytic holonomy $C^*$-algebra restricted to a finite path groupoid $ΠΓΣ \rightrightarrows VΓ$ and a point norm continuous action of the finite path-diffeomorphism group $Diff(VΓ)$ on this algebra. Clearly the right-, left- and inner-translations $R_φ, L_φ$ and $I_φ$ are constructed such that generalises. But note that, in the infinite case considered by Fleischhack the action of the bisections $Β(ΠΣ)$ are not point-norm continuous implemented. The advantage of the usage of bisections is that, the map $σ \mapsto t \circ σ$ is a group morphism between the group $Β(ΠΣ)$ of bisections in $ΠΣ \rightrightarrows Σ$ and the group $Diff(Σ)$ of diffeomorphisms in $Σ$. Consequently there is an action of the group of diffeomorphisms in $Σ$ on the finite path groupoid, which is used to define an action of the group of diffeomorphisms in $Σ$ on the analytic holonomy $C^*$-algebra.
Transformations in finite graph systems

To proceed it is necessary to transfer the notion of bisectons and right-translations to finite graph systems. A right-translation \( R_{\sigma} \) is a mapping that maps graphs to graphs. Each graph is a finite union of independent edges. This causes problems. Since the definition of right-translation in a finite graph system \( \mathcal{P}_T \) is often not well-defined for all bisectons in the finite graph system and all graphs. For example if the graph \( \Gamma := \{ \gamma_1, \gamma_2 \} \) is disconnected and the bisection \( \tilde{\sigma} \) in the finite path groupoid \( \mathcal{P}_T \) over \( V_T \) is defined by \( \tilde{\sigma}(s(\gamma_1)) = \gamma_1, \tilde{\sigma}(s(\gamma_2)) = \gamma_2, \tilde{\sigma}(t(\gamma_1)) = \gamma_1^{-1} \) and \( \tilde{\sigma}(t(\gamma_2)) = \gamma_2^{-1} \) where \( V_T := \{ s(\gamma_1), t(\gamma_1), s(\gamma_2), t(\gamma_2) \} \). Let \( \Gamma_{s(\gamma_1)} \) be the set given by the elements \( \llbracket 1 \rrbracket_{s(\gamma_1)}, \llbracket 2 \rrbracket_{s(\gamma_1)}, \llbracket 1 \rrbracket_{s(\gamma_2)} \) and \( \llbracket 2 \rrbracket_{s(\gamma_2)} \). Then notice that, a bisection \( \sigma_{\Gamma^*} \), which maps a set of vertices in \( V_T \) to a set of paths in \( \mathcal{P}_T \), is given for example by \( \sigma_{\Gamma^*}(V_T) := \{ \gamma_1, \gamma_2, \gamma_1^{-1}, \gamma_2^{-1} \} \). In this case the right-translation \( R_{\sigma_{\Gamma^*}}(\Gamma) \) is equivalent to \( \{ \gamma_1, \gamma_2, \gamma_1^{-1}, \gamma_2^{-1} \} \), which is not a set of independent edges and hence not a graph. Loosely speaking the graph-diffeomorphism acts on all vertices in the set \( V_T \) and hence implements four new edges. But a bisection \( \sigma_{\Gamma^*} \), which maps a subset \( V := \{ s(\gamma_1), s(\gamma_2) \} \) of \( V_T \) to a set of paths, leads to a translation \( R_{\sigma_{\Gamma^*}}(\Gamma) \) is equivalent to \( \{ \gamma_1, \gamma_2, \gamma_1^{-1}, \gamma_2^{-1} \} \), which is indeed a graph. Set \( \Gamma' := \{ \gamma_1 \} \) and \( V' := \{ s(\gamma_1) \} \). Then observe that, for a restricted bisection, which maps a set \( V' \) of vertices in \( V_T \) to a set of paths in \( \mathcal{P}_T \), the right-translation become \( R_{\sigma_{\Gamma^*}}(\Gamma') \) is a subgraph of \( \Gamma' \). Hence in the simplest case new edges are emerging. The next definition of the right-translation shows that composed paths arise, too.

**Definition 2.26.** Let \( \Gamma \) be a graph, \( \mathcal{P}_T \rightarrow \mathcal{P}_T \) be a finite path groupoid and let \( \sigma_{\Gamma^*} \) be a finite graph system. Moreover the set \( V_T \) is given by \( \{ v_1, ..., v_2 \} \).

A bisection of a finite graph system \( \mathcal{P}_T \) is a map \( \sigma_{\Gamma^*} : V_T \rightarrow \mathcal{P}_T \) such that there exists a bisection \( \tilde{\sigma} \in \mathcal{B}(\mathcal{P}_T \Sigma) \) such that \( \sigma_{\Gamma^*}(V) = \{ \tilde{\sigma}(v_i) : v_i \in V \} \) whenever \( V \) is a subset of \( V_T \).

Define a restriction \( \sigma_{\Gamma^*} : V_T \rightarrow \mathcal{P}_{\Gamma^*} \) of a bisection \( \sigma_{\Gamma^*} \) in \( \mathcal{P}_T \) by

\[
\sigma_{\Gamma^*}(V) := \{ \tilde{\sigma}(w_k) : w_k \in V \}
\]

for each subgraph \( \Gamma' \) of \( \Gamma \) and \( V \subseteq V_T \).

A right-translation in the finite graph system \( \mathcal{P}_T \) is a map \( R_{\sigma_{\Gamma^*}} : \mathcal{P}_T \rightarrow \mathcal{P}_{\Gamma^*} \), which is given by a bisection \( \sigma_{\Gamma^*} : V_T \rightarrow \mathcal{P}_T \) such that

\[
R_{\sigma_{\Gamma^*}}(\Gamma) = R_{\sigma_{\Gamma^*}}(\{ \gamma_1', ..., \gamma_{M}', \llbracket v_i \rrbracket : w_i \in \{ s(\gamma_1'), ..., s(\gamma_K') \} \in V_T : s(\gamma_i') \neq s(\gamma_j') \forall i \neq j \} \setminus V_{\Gamma^*})
\]

\[
= \{ \gamma_1', ..., \gamma_{K}', s(\gamma_1') \circ \tilde{\sigma}(t(\gamma_{j+1}')), ..., s(\gamma_{K}') \circ \tilde{\sigma}(t(\gamma_{K}')), \llbracket w_i \rrbracket : w_i \in \{ s(\gamma_1'), ..., s(\gamma_K') \} \in V_T : s(\gamma_1') \neq s(\gamma_j') \forall i \neq j \} \setminus V_{\Gamma^*}, \quad t(\gamma_i') \neq t(\gamma_j') \forall i \neq j, i, j \in [j+1, M] \}
\]

where \( \tilde{\sigma} \in \mathcal{B}(\mathcal{P}_T \Sigma), K := |\Gamma'| \) and \( M := |\Gamma^*| \), \( V_T \) is the set of all source vertices of \( \Gamma' \) and such that \( \Gamma'' := \{ \gamma_1', ..., \gamma_{M}' \} \) is a subgraph of \( \Gamma' \) and \( \Gamma'' \) is a subgraph of \( \Gamma' \).

To derive that, for \( \tilde{\sigma}(t(\gamma_i)) = \gamma_i^{-1} \) it is true that \( (t \circ \tilde{\sigma})(s(\gamma_i)^{-1}) = s(\gamma_i) = (t \circ \tilde{\sigma})(t(\gamma_i)) \) holds.

**Example 2.3:** Let \( \Gamma \) be a disconnected graph. Then for a bisection \( \tilde{\sigma} \in \mathcal{B}(\mathcal{P}_T \Sigma) \) such that \( \sigma(t(\gamma_i)) = \gamma_i^{-1} \) for all \( 1 \leq i \leq |\Gamma| \) it is true that

\[
R_{\sigma_{\Gamma^*}}(\Gamma) = \{ \gamma_1 \circ \tilde{\sigma}(t(\gamma_1)), ..., \gamma_N \circ \tilde{\sigma}(t(\gamma_N)), \llbracket s(\gamma_1) \rrbracket \circ \tilde{\sigma}(s(\gamma_1)), ..., \llbracket s(\gamma_N) \rrbracket \circ \tilde{\sigma}(s(\gamma_N)) \}
\]

yields. Set \( \Gamma' := \{ \gamma_1', ..., \gamma_{M}' \} \), then derive

\[
R_{\sigma_{\Gamma^*}}(\Gamma') = \{ \gamma_1' \circ \tilde{\sigma}(t(\gamma_1')), ..., \gamma_{M}' \circ \tilde{\sigma}(t(\gamma_{M}')), \llbracket s(\gamma_1) \rrbracket \circ \tilde{\sigma}(s(\gamma_1')), ..., \llbracket s(\gamma_N-M) \rrbracket \circ \tilde{\sigma}(s(\gamma_N-M)) \}
\]

if \( \Gamma = \Gamma' \cup \{ \gamma_1, ..., \gamma_{N-M} \} \).

To understand the definition of the right-translation notice the following problem.

**Problem 2.1:** Consider a subgraph \( \Gamma \) of \( \Gamma := \{ \gamma_1, \gamma_2, \gamma_3, \gamma_4 \} \), a map \( \tilde{\sigma} : V_T \rightarrow \mathcal{P}_T \Sigma \). Then the map

\[
R_{\sigma_{\Gamma^*}}(\Gamma) = \{ \gamma_1 \circ \gamma_1^{-1}, \gamma_2 \circ \llbracket t(\gamma_2), \gamma_3 \circ \llbracket t(\gamma_3), \llbracket s(\gamma_1) \circ \gamma_4 \} =: \Gamma_{\sigma}
\]
is not a right-translation. This follows from the following fact. Notice that, the map $\sigma$ maps $t(\gamma_1) \rightarrow s(\gamma_1)$, $t(\gamma_2) \rightarrow t(\gamma_2)$, $t(\gamma_3) \rightarrow t(\gamma_3)$ and $s(\gamma_1) \rightarrow t(\gamma_4)$. Then the map $\tilde{\sigma}$ is not a bisection in the finite path groupoid $\mathcal{P}_F\Sigma$ over $V_F$ and does not define a right-translation $R_{\sigma_{\tilde{\Gamma}}}$ in the finite graph system $\mathcal{P}_F$.

This is a general problem. For every bisection $\tilde{\sigma}$ in a finite path groupoid such that a graph $\Gamma := \{\gamma\}$ is translated to $\{\gamma \circ \tilde{\sigma}(t(\gamma)), \tilde{\sigma}(s(\gamma))\}$. Hence either such translations in the graph system are excluded or the definition of the bisections has to be restricted to maps such that the map $t \circ \tilde{\sigma}$ is not bijective. Clearly, the restriction of the right-translation such that $\tilde{\Gamma}$ is mapped to $\{\gamma \circ \tilde{\sigma}(t(\gamma)), \tilde{\sigma}(s(\gamma))\}$ implies that a simple path orientation transformation is not implemented by a right-translation.

Furthermore there is an ambiguity for graph containing to paths $\gamma_1$ and $\gamma_2$ such that $t(\gamma_1) = t(\gamma_2)$. Since in this case a bisection $\sigma$, which maps $t(\gamma_1)$ to $t(\gamma_3)$, the right-translation is $\{\gamma_1 \circ \gamma_3, \gamma_2 \circ \gamma_3\}$, is not a graph anymore.

**Example 2.4:** Otherwise there is for example a subgraph $\Gamma'$ of $\hat{\Gamma} := \{\gamma_1, \gamma_2, \gamma_3, \gamma_4\}$ and a bisection $\tilde{\sigma}_\Gamma$ such that

$$\Gamma' := \{\gamma_1, \gamma_2, \gamma_3\}$$

Notice that, $t(\gamma_1) \rightarrow s(\gamma_1)$, $t(\gamma_2) \rightarrow t(\gamma_2)$, $t(\gamma_3) \rightarrow t(\gamma_3)$ and $t(\gamma_4) \rightarrow t(\gamma_4)$. Hence the the map $\tilde{\sigma}_\Gamma : V_{\hat{\Gamma}} \rightarrow \mathcal{P}_F\Sigma$ is bijective map and consequently a bisection. The bisection $\sigma_{\hat{\Gamma}}$ in the graph system $\mathcal{P}_F$ defines a right-translation $R_{\sigma_{\hat{\Gamma}}}$ in $\mathcal{P}_F$.

Moreover for a subgraph $\Gamma'' := \{\gamma_2, \gamma_3\}$ of the graph $\hat{\Gamma} := \{\gamma_1, \gamma_2, \gamma_3\}$ there exists a map $\sigma_{\hat{\Gamma}} : V_{\hat{\Gamma}} \rightarrow \mathcal{P}_F$ such that

$$R_{\sigma_{\hat{\Gamma}}}(\Gamma'') = \{\gamma_2, \gamma_3, \tilde{\sigma}(s(\gamma_1))\} = \{\gamma_2, \gamma_3, \gamma_1\}$$

where $t(\gamma_2) \rightarrow t(\gamma_2)$, $t(\gamma_3) \rightarrow t(\gamma_3)$ and $s(\gamma_1) \rightarrow t(\gamma_1)$. Consequently in this example the map $\tilde{\sigma}_{\hat{\Gamma}}$ is a bisection, which defines a right-translation in $\mathcal{P}_\Gamma$.

Note that, for a graph $\Gamma$ such that $\hat{\Gamma}$ and $\tilde{\Gamma}$ are subgraphs the bisection $\sigma_{\hat{\Gamma}}$ extends to a bisection $\sigma$ in $\mathcal{P}_\Gamma$ and $\sigma_{\hat{\Gamma}}$ extends to a bisection $\tilde{\sigma}$ in $\mathcal{P}_\Gamma$. 15
Moreover the bisections of a finite graph system are transferred, analogously, to bisections of a finite path groupoid $\mathcal{P}_T \Sigma \equiv V_T$ to the group $G^{[1]}$. Let $\sigma \in \mathcal{B}(\mathcal{P}_T)$ and $(h_T, h_T') \in \text{Hom}(\mathcal{P}_T, G^{[1]})$. Thus there are two maps
\[
h_T \circ R_\sigma : \mathcal{P}_T \rightarrow G^{[1]} \quad \text{and} \quad h_T \circ (t \circ \sigma) : V_T \rightarrow \{e_G\}
\]
which defines a holonomy map for a finite graph system if $\sigma$ is suitable.

Now, a similar right-translation in a finite graph system in comparison to the right-translation $R_{\sigma(v)}$ in a finite path groupoid is studied. Let $\sigma' : V_T \rightarrow \mathcal{P}_T$ be a restriction of $\sigma_T \in \mathcal{B}(\mathcal{P}_T)$. Moreover let $V$ be a subset of $V_T$, let $\Gamma''$ be a subgraph of $\Gamma'$ and $\Gamma'''$ be a subgraph of $\Gamma''$. Then a right-translation is given by
\[
R_{\sigma'\gamma'}(\Gamma''') = \begin{cases} \{\gamma'' \in \gamma M, \ll w_i : w_i \in \{s(\gamma_{i1}), ..., s(\gamma_{iK}) \in V_{T'} : s(\gamma_{i}) \neq s(\gamma_{j}) \forall i \neq j \} \setminus V_{T''} \} : V_{T''} \subset V \\ \{\ll_x \in V \setminus V_{T''} \cup \{\Gamma'' \setminus \Gamma'''\} : V_{T''} \not\subset V, V_{T''''} \subset V \end{cases}
\]
Loosely speaking, the action of a path-diffeomorphism is somehow localised on a fixed vertex set $V$.

For example note that for a subgraph $\Gamma' \equiv \{\gamma \circ \gamma'\}$ of $\Gamma \equiv \{\gamma, \gamma'\}$ and a subset $V \equiv \{t(\gamma)\}$ of $V_T$, it is true that
\[
(\mathfrak{h} \circ R_{\sigma'\gamma'})(\gamma \circ \gamma') = (\mathfrak{h} \circ R_{\sigma'\gamma'})(\gamma) \circ (\mathfrak{h} \circ R_{\sigma'\gamma'})(\gamma') = \mathfrak{h}(\gamma \circ \gamma') \circ (\mathfrak{h} \circ R_{\sigma'\gamma'})(\gamma)
\]
yields whenever $\sigma_T \in \mathcal{B}(\mathcal{P}_T \Sigma)$. For a specific bisection $\sigma_T$ it is true that
\[
(\mathfrak{h} \circ R_{\sigma'\gamma'})(\gamma) = \mathfrak{h}(\gamma \circ \gamma') = (\mathfrak{h} \circ R_{\sigma'\gamma'})(\gamma) \circ (\mathfrak{h} \circ R_{\sigma'\gamma'})(\gamma')
\]
holds whenever $\sigma_T \in \mathcal{B}(\mathcal{P}_T \Sigma)$, $\sigma_T(t(\gamma')) = \ll t(\gamma')$ and $\sigma_T(t(\gamma)) = \ll t(\gamma)$. Let $\sigma$ be the bisection in the finite path groupoid $\mathcal{P}_T \Sigma$ that defines the bisection $\sigma$ in $\mathcal{P}_T$. Then the last statement is true, since $R_{\sigma_T} = \gamma' \circ \gamma'^{-1}$ requires $\sigma_T : t(\gamma') \rightarrow s(\gamma')$ and $R_{\sigma_T} = \gamma \circ \gamma'$ needs $\sigma_T : t(\gamma) \rightarrow t(\gamma')$, where $s(\gamma') = t(\gamma)$. Then $R_{\sigma_T}(\gamma)$ and $R_{\sigma_T(t(\gamma'))}(\gamma)$ coincide if $\sigma_T(t(\gamma)) = \sigma_T(t(\gamma'))$ and $\sigma_T(t(\gamma')) = \ll_{t(\gamma)}$ holds.

**Problem 2.2:** Let $\Gamma'$ be a subgraph of the graph $\Gamma$, $\sigma_T$ be a bisection in $\mathcal{P}_T$, $\sigma' : V_T \rightarrow \mathcal{P}_T$ be a restriction of $\sigma_T \in \mathcal{B}(\mathcal{P}_T)$. Moreover let $V$ be a subset of $V_T$, let $\Gamma'' \equiv \{\gamma \circ \gamma'\}$ be a subgraph of $\Gamma'$. Let $(\gamma, \gamma') \in \mathcal{P}_T \Sigma^{(2)}$.

Then even for a suitable bisection $\sigma_T$ in $\mathcal{P}_T$ it follows that
\[
R_{\sigma'\gamma'}(\gamma \circ \gamma') \neq R_{\sigma'\gamma'}(\gamma) \circ R_{\sigma'\gamma'}(\gamma')
\]
yields. This is a general problem. In comparison with problem 2.3 11 the multiplication map $\circ$ is not well-defined and hence
\[
R_{\sigma'\gamma'}(\gamma \circ \gamma') \circ R_{\sigma'\gamma'}(\gamma')
\]
is not well-defined. Recognize that, $R_{\sigma'\gamma'} : \mathcal{P}_T \rightarrow \mathcal{P}_T$.

Consequently in general it is not true that
\[
(\mathfrak{h} \circ R_{\sigma'\gamma'})(\gamma \circ \gamma') = \mathfrak{h}(R_{\sigma'\gamma'}(\gamma) \circ R_{\sigma'\gamma'}(\gamma')) = (\mathfrak{h} \circ R_{\sigma'\gamma'})(\gamma) \circ (\mathfrak{h} \circ R_{\sigma'\gamma'})(\gamma')
\]
yields.

With no doubt the left-translation $L_{\sigma_T}$ and the inner automorphisms $I_{\sigma_T}$ in a finite graph system $\mathcal{P}_T$ for every $\Gamma' \in \mathcal{P}_T$ are defined similarly.

**Definition 2.27.** Let $\sigma_T \in \mathcal{B}(\mathcal{P}_T)$ be a bisection in the finite graph system $\mathcal{P}_T$. Let $R_{\sigma_T\gamma'}$ be a right-translation, where $V$ is a subset of $V_T$.

Then the pair $(\Phi_T, \varphi_T)$ defined by $\Phi_T = R_{\sigma_T\gamma'}$ (or, respectively, $\Phi_T = L_{\sigma_T\gamma'}$, or $\Phi_T = I_{\sigma_T\gamma'}$) for a subset $V \subset V_T$ and $\varphi_T = t \circ \sigma_T$ is called a graph-diffeomorphism of a finite graph system. Denote the set of finite graph-diffeomorphisms by $\text{Diff}(\mathcal{P}_T)$.
Let $\Gamma'$ be a subgraph of $\Gamma$ and $\sigma_{\Gamma'}$ be a restriction of bisection $\sigma_\Gamma$ in $\mathcal{P}_\Gamma$. Then for example another graph-diffeomorphism $(\Phi_\Gamma, \varphi_{\Gamma'})$ in Diff$(\mathcal{P}_\Gamma)$ is defined by $\Phi_\Gamma = R_{\sigma_\Gamma}(V)$ for a subset $V \subseteq V_{\Gamma'}$ and $\varphi_{\Gamma'} = t \circ \sigma_{\Gamma'}$.

Remembering that the set of bisections of a finite path groupoid forms a group (refer to 2.21) one may ask if the bisections of a finite graph system form a group, too.

**Proposition 2.28.** The set of bisections $\mathfrak{B}(\mathcal{P}_\Gamma)$ in a finite graph system $\mathcal{P}_\Gamma$ forms a group.

**Proof:** Let $\Gamma$ be a graph and let $V_{\Gamma'}$ be equivalent to the set $\{v_1, \ldots, v_{NV}\}$.

First two different multiplication operations are studied. The studies are comparable with the results of the definition 2.26 of a right-translation in a finite graph system. The easiest multiplication operation is given by $\ast_1$, which is defined by

$$((\sigma \ast_1 \sigma')(V_{\Gamma'}) := (\{\tilde{\sigma} \ast_1 \tilde{\sigma}'\}(v_1), \ldots, (\tilde{\sigma} * \tilde{\sigma}'(v_{2N}) : v_i \in V_{\Gamma'})$$

where $\ast$ denotes the multiplication of bisections on the finite path groupoid $\mathcal{P}_\Gamma \Sigma \equiv V_{\Gamma'}$. Notice that, this operation is not well-defined in general. In comparison with the definition of the right-translation in a finite graph system one has to take care. First the set of vertices doesn’t contain any vertices twice, the map $\sigma$ in the finite path system is bijective, the mapping $\sigma$ maps each set to a set of vertices containing no vertices twice and the situation in problem 2.24 has to be avoided.

Fix a bisection $\tilde{\sigma}$ in a finite path groupoid $\mathcal{P}_\Gamma \Sigma \equiv V_{\Gamma'}$. Let $V_{\sigma_0}$ be a subset of $V_{\Gamma'}$ where $\Gamma := \{\gamma_1, \ldots, \gamma_N\}$ and for each $v_i$ in $V_{\sigma_0}$ it is true that $v_i \neq v_j$ and $v_i \neq (t \circ \sigma)(v_j)$ for all $i \neq j$. Define the set $V_{\sigma_0, \sigma'}$ to be equal to a subset of the set of all vertices $(v_k \in V_{\sigma_0} : 1 \leq k \leq 2N)$ such that each pair $(v_i, v_j)$ of vertices in $V_{\sigma_0, \sigma'}$ satisfies $(t \circ (\tilde{\sigma} * \tilde{\sigma}'))(v_i) \neq (t \circ \sigma')(v_j)$ and $(t \circ \sigma')(v_i) \neq (t \circ \sigma')(v_j)$ for all $i \neq j$. Define

$$W_{\sigma_0, \sigma'} := \{v_i \in \{V_{\sigma_0} \cap V_{\sigma_0'} \} \setminus \{v_\sigma \cup \sigma' \} \setminus \{v_i \neq v_j \} \setminus \{v_i \neq v_j \} : 1 \leq i, j \leq k\}$$

The set $V_{\sigma_0, \sigma'}$ is a subset of all vertices $(v_k \in V_{\sigma_0, \sigma'} : 1 \leq k \leq 2N)$ such that each pair $(v_i, v_j)$ of vertices in $V_{\sigma_0, \sigma'}$ satisfies $(t \circ (\tilde{\sigma} * \tilde{\sigma}'))(v_i) \neq (t \circ (\tilde{\sigma} * \tilde{\sigma}'))(v_j)$ and $(t \circ (\tilde{\sigma} * \tilde{\sigma}'))(v_i) \neq (t \circ (\tilde{\sigma} * \tilde{\sigma}'))(v_j)$ for all $i \neq j$.

Consequently define a second multiplication on $\mathfrak{B}(\mathcal{P}_\Gamma)$ similarly to the operation $\ast_1$. This is done by the following definition. Set

$$(\sigma \ast_{2} \sigma')(V_{\Gamma'}) := (\{\tilde{\sigma} \ast_1 \tilde{\sigma}'\}(v_1), \ldots, (\tilde{\sigma} \ast_1 \tilde{\sigma}'(v_{2N}) : v_1, \ldots, v_{N} \in V_{\sigma_0, \sigma'}, 1 \leq k \leq 2N)$$

Hence the inverse is supposed to be $\sigma_1^{-1}(V_{\Gamma'}) = \sigma((t \circ \sigma)^{-1}(V_{\Gamma'}))^{-1}$ such that

$$(\sigma \ast_{2} \sigma')(V_{\Gamma'}) := (\{\tilde{\sigma} \ast_1 \tilde{\sigma}'\}(v_1), \ldots, (\tilde{\sigma} \ast_1 \tilde{\sigma}'(v_{2N}) : v_1, \ldots, v_{N} \in V_{\sigma_0, \sigma'}, 1 \leq k \leq 2N)$$

Hence the inverse is supposed to be $\sigma_1^{-1}(V_{\Gamma'}) = \sigma((t \circ \sigma)^{-1}(V_{\Gamma'}))^{-1}$ such that

$$(\sigma \ast_{2} \sigma')(V_{\Gamma'}) := (\{\tilde{\sigma} \ast_1 \tilde{\sigma}'\}(v_1), \ldots, (\tilde{\sigma} \ast_1 \tilde{\sigma}'(v_{2N}) : v_1, \ldots, v_{N} \in V_{\sigma_0, \sigma'}, 1 \leq k \leq 2N)$$

Notice that, the problem 2.24 is solved by a multiplication operation $\sigma_2$, which is defined similarly to $\ast_2$. Hence the equality of (14) is available and consequently (15) is true. Furthermore a similar remark to 12 can be done.

**Example 2.5.** Now consider the following example. Set $\Gamma' := \{\gamma_1, \gamma_3\}$, let $\Gamma := \{\gamma_1, \gamma_2, \gamma_3\}$ and $V_{\Gamma'} := \{s(\gamma_1), t(\gamma_1), s(\gamma_2), t(\gamma_2), s(\gamma_3), t(\gamma_3) : s(\gamma_1) \neq s(\gamma_2), t(\gamma_1) \neq t(\gamma_2), s(\gamma_2) \neq s(\gamma_3), t(\gamma_2) \neq t(\gamma_3) \forall i \neq j\}.

Set $V_{\Gamma}$ be equal to $\{s(\gamma_1), s(\gamma_2), s(\gamma_3)\}$. Take two maps $\sigma$ and $\sigma'$ such that $\sigma'(V) = \{\gamma_1, \gamma_3\}$, $\sigma(V) = \{\gamma_2\}$, where $(t \circ \tilde{\sigma})(s(\gamma_3)) = t(\gamma_3)$, $(\tilde{\sigma}'(s(\gamma_3))) = \gamma_3$, $(\sigma'(s(\gamma_1))) = \gamma_1$ and $(\tilde{\sigma}(t(\gamma_3))) = \gamma_2$. Then $s(\gamma_3) \in V_{\sigma', \sigma'}$ and $s(\gamma_1) \in W_{\sigma', \sigma'}$. Derive

$$(\sigma \ast_1 \sigma')(V_{\Gamma'}) = \{\gamma_3 \circ \gamma_2, \gamma_1\}$$

Then conclude that,

$$(\sigma \ast_2 \sigma')(V_{\Gamma'}) = \{\gamma_3 \circ \gamma_2, \gamma_1\}$$
holds. Notice that
\[(σ * _2 σ')(V) \neq (σ' * _2 σ)(V) = \{γ_2, γ_1, γ_3\}\]
is true. Finally obtain
\[(σ * _2 σ^{-1})(V_T) = \{γ_3 \circ γ_3^{-1}, γ_1 \circ γ_1^{-1}\} = \{I_{s(γ_3)}, I_{s(γ_1)}\}\]
Let \(σ'(V_T) = \{γ_1, γ_3\}\) and \(σ(γ_1) = \{γ_2, γ_4\}\). Then notice that,
\[(σ * 1 σ')(V_T) = \{γ_3 \circ γ_2, γ_1\}\]
and
\[(σ * _2 σ')(V_T) = \{γ_3 \circ γ_2, γ_1, γ_4\}\]
yields.

Furthermore assume supplementary that \(ℓ(γ_3) = ℓ(γ_1)\) holds. Then calculate the product of the maps \(σ\) and \(σ'\):
\[(σ * 1 σ')(V) = \{γ_3 \circ γ_2, γ_1 \circ γ_2\} \notin \mathcal{P}_T\]
and
\[(σ * _2 σ')(V_T) = \{I_{t(γ_1)}, I_{t(γ_3)}\} \in \mathcal{P}_T\]

The group structure of \(\mathcal{B}(\mathcal{P}_T)\) transferes to \(G\). Let \(σ\) be a bisection in the finite path groupoid \(\mathcal{P}_T \xrightarrow{γ} V_T\), which defines a bisection \(σ\) in \(\mathcal{P}_T\) and let \(σ'\) be a bisection in \(\mathcal{P}_T \xrightarrow{γ'} V_T\), which defines another bisection \(σ'\) in \(\mathcal{P}_T\). Let \(V_{σ,σ'}\) be equal to \(V_T\), then derive
\[
\begin{align*}
&\mathcal{h}_T((σ * _2 σ')(V_T)) = \{\mathcal{h}_T((σ * σ')(v_1)),...,\mathcal{h}_T((σ * σ')(v_{2N}))\} \\
&= \mathcal{h}_T(σ'(V_T) \circ σ(t(σ'(V_T)))) = \{\mathcal{h}_T(σ'(v) \circ σ(t(σ'(v_1))),...,\mathcal{h}_T(σ'(v_{2N}) \circ σ(t(σ'(v_{2N}))))\} \\
&= \{\mathcal{h}_T(σ(v))h_T(σ(t(σ'(v_1)))),...,\mathcal{h}_T(σ(v_{2N}))h_T(σ(t(σ'(v_{2N}))))\} \\
&= \mathcal{h}_T(σ(V_T))h_T(σ(σ'(V_T)))
\end{align*}
\]
Consequently the right-translation in the finite product \(G^{[γ]}\) is definable.

**Definition 2.29.** Let \(σ_{γ'}\) be in \(\mathcal{B}(\mathcal{P}_T)\), \(Γ'\) a subgraph of \(Γ\), \(Γ''\) a subgraph of \(Γ'\) and \(R_{σ_{γ'}}\) a right-translation, \(L_{σ_{γ'}}\) a left-translation and \(I_{σ_{γ'}}\) an inner-translation in \(\mathcal{P}_T\).

Then the **right-translation in the finite product** \(G^{[γ]}\) is given by
\[
\mathcal{h}_T \circ R_{σ_{γ'}} : \mathcal{P}_T \rightarrow G^{[γ]}, \quad Γ'' \mapsto (\mathcal{h}_T \circ R_{σ_{γ'}})(Γ'')
\]
Furthermore define the **left-translation in the finite product** \(G^{[γ]}\) by
\[
\mathcal{h}_T \circ L_{σ_{γ'}} : \mathcal{P}_T \rightarrow G^{[γ]}, \quad Γ'' \mapsto (\mathcal{h}_T \circ L_{σ_{γ'}})(Γ'')
\]
and the **inner-translation in the finite product** \(G^{[γ]}\)
\[
\mathcal{h}_T \circ I_{σ_{γ'}} : \mathcal{P}_T \rightarrow G^{[γ]}, \quad Γ'' \mapsto (\mathcal{h}_T \circ I_{σ_{γ'}})(Γ'')
\]
such that \(I_{σ_{γ'}} = L_{σ_{γ'}}^{-1} \circ R_{σ_{γ'}}\).

**Lemma 2.30.** It is true that \(R_{σ_{γ'}σ_{γ'}'} = R_{σ_{γ'}} \circ R_{σ_{γ'}}, L_{σ_{γ'}σ_{γ'}'} = L_{σ_{γ'}} \circ L_{σ_{γ'}}, I_{σ_{γ'}σ_{γ'}'} = I_{σ_{γ'}} \circ I_{σ_{γ'}}\) for all bisections \(σ_{γ'}\) and \(σ_{γ'}'\) in \(\mathcal{B}(\mathcal{P}_T)\).
There is an action of $\mathcal{B}(\mathcal{P}_\Gamma)$ on $G^{[\Gamma]}$ by

$$(\zeta_{\sigma^r} \circ h_{\Gamma})(\Gamma'') := (h_{\Gamma} \circ R_{\sigma^r})(\Gamma'')$$

whenever $\sigma^r \in \mathcal{B}(\mathcal{P}_\Gamma)$, $\Gamma'' \in \mathcal{P}_\Gamma$ and $\Gamma' \in \mathcal{P}_\Gamma$. Then for another $\bar{\sigma} \in \mathcal{B}(\mathcal{P}_\Gamma)$ it is true that,

$$(\zeta_{\sigma^r} \circ \zeta_{\bar{\sigma}^r} \circ h_{\Gamma})(\Gamma'') = (h_{\Gamma} \circ R_{\sigma^r \bar{\sigma}^r})(\Gamma'') = (\zeta_{\sigma^r \bar{\sigma}^r} \circ h_{\Gamma})(\Gamma'')$$

yields.

Recall that, the map $\bar{\sigma} \mapsto t \circ \bar{\sigma}$ is a group isomorphism between the group of bisections $\mathcal{B}(\mathcal{P}_\Gamma \Sigma)$ and the group $\text{Diff}(\mathcal{V}_\Gamma)$ of finite diffeomorphisms in $\mathcal{V}_\Gamma$. Therefore if the graphs $\Gamma' = \Gamma''$ contain only the path $\gamma$, then the action $\zeta_{\sigma}$ is equivalent to an action of the finite diffeomorphism group $\text{Diff}(\mathcal{V}_\Gamma)$. Loosely speaking, the graph-diffeomorphisms $(R_{\sigma^r}(v), t \circ \sigma^r)$ on a subgraph $\Gamma'''$ of $\Gamma''$ transform graphs and respect the graph structure of $\Gamma''$. The diffeomorphism $t \circ \sigma$ in the finite path groupoid only implements the finite diffeomorphism in $\Sigma$, but it doesn’t adopt any path groupoid or graph preserving structure. Summarising the bisections of a finite graph system respect the graph structure and implement the finite diffeomorphisms in $\Sigma$. There is another reason why the group of bisections is more fundamental than the path- or graph-diffeomorphism group. In $[9, 7]$ the concept of $C^*$-dynamical systems has been studied. It turns out that, there are three different $C^*$-dynamical systems, each is build from the analytic holonomy $C^*$-algebra and a point-norm continuous action of the group of bisections of a finite graph system. The actions are implemented by one of the three translations, i.e. the left-, right- or inner-translation in the finite product $G^{[\Gamma]}$.

Transformations and discretised surface sets

Now restricted sets of bisections are concerned. Consider a finite set of paths starting at a discretised surface. The idea is to define a bisection $\sigma$ such that the map $t \circ \sigma$ preserves the set $S_\Sigma$ of discretised surfaces and each path of the certain set of paths composed with the bisection $\sigma$ at the target vertex of this path is again a path that start at a discretised surface. The definition follows.

Define the set $V^{S_\Sigma}$, which contains all target vertices of paths in $\mathcal{P}_\Gamma^{S_\Sigma}$ $\Sigma$. Note that, the base point $v$ with respect to $\mathcal{P}_\Gamma \Sigma^v$ is the source vertex of all paths in $\mathcal{P}_\Gamma \Sigma^v$ and all paths in $\mathcal{P}_\Gamma \Sigma^v$ are contained in $\mathcal{P}_\Gamma^{S_\Sigma}$ for all $v \in S_\Sigma$. Denote the set of bisections, which are bijective maps from the set $V^{S_\Sigma}$ to paths in $\mathcal{P}_\Gamma^{S_\Sigma}$, by $\mathcal{B}(\mathcal{P}_\Gamma^{S_\Sigma})$. On the level of graphs the restricted set of bisections in a graph system $\mathcal{P}_\Gamma$ is denoted by $\mathcal{B}(\mathcal{P}_\Gamma^{S_\Sigma})$. Denote the set of graph-diffeomorphisms, which are defined by a bisection in $\mathcal{B}(\mathcal{P}_\Gamma^{S_\Sigma})$ and the right-translation $R_{\sigma}$, by the term $\text{Diff}(\mathcal{P}_\Gamma^{S_\Sigma})$.

2.3 The quantum flux operators associated to surfaces and graphs

The quantum flux operators presented by Lie algebra elements associated to surfaces and graphs

The quantum analog of a classical connection $A_\gamma(v)$ is given by the holonomy along a path $\gamma$ and is denoted by $\mathfrak{h}(\gamma)$. The quantum flux operator $E_S(\gamma)$, which replaces the classical flux variable $E(S, f^S)$, is given by a map $E_S$ from a graph to the Lie algebra $\mathfrak{g}$. Let $\text{Exp}$ be the exponential map from the Lie algebra $\mathfrak{g}$ to $G$ and set $U_t(E_S(\gamma)) := \text{Exp}(t E_S(\gamma))$. Then the quantum flux operator $E_S(\gamma)$ and the quantum holonomies $\mathfrak{h}(\gamma)$ satisfy the following canonical commutator relation

$$E_S(\gamma) \mathfrak{h}(\gamma) = i \frac{d}{dt} \bigg|_{t=0} U_t(E_S(\gamma)) \mathfrak{h}(\gamma)$$

where $\gamma$ is a path that intersects the surface $S$ in the target vertex of the path and lies below with respect to the surface orientation of $S$.

In this section different definitions of the quantum flux operator, which is associated to a fixed surface $S$, are presented. For example the quantum flux operator $E_S$ is defined to be a map from a graph $\Gamma$ to a direct sum $\mathfrak{g} \oplus \mathfrak{g}$ of the Lie algebra $\mathfrak{g}$ associated to the Lie group $G$. This is related to the fact that, one distinguishes between paths that are ingoing and paths that are outgoing with respect to the surface orientation of $S$. If there are no intersection points of the surface $S$ and the source or target vertex of a path $\gamma_i$ of a graph $\Gamma$, then the map maps the path $\gamma_i$ to zero in both entries. For different surfaces or for a fixed surface different maps will refer to different quantum flux operators. Furthermore, the quantum flux operators is also defined as maps form the graph $\Gamma$ to direct sum $\mathcal{E} \oplus \mathcal{E}$ of the universal enveloping algebra $\mathcal{E}$ of $\mathfrak{g}$.
Definition 2.31. Let $\tilde{S}$ be a finite set $\{S_i\}$ of surfaces in $\Sigma$, which is closed under a flip of orientation of the surfaces. Let $\Gamma$ be a graph such that each path in $\Gamma$ satisfies one of the following conditions

- the path intersects each surface in $\tilde{S}$ in the source vertex of the path and there are no other intersection points of the path and any surface contained in $\tilde{S}$,
- the path intersects each surface in $\tilde{S}$ in the target vertex of the path and there are no other intersection points of the path and any surface contained in $\tilde{S}$,
- the path intersects each surface in $\tilde{S}$ in the source and target vertex of the path and there are no other intersection points of the path and any surface contained in $\tilde{S}$,
- the path does not intersect any surface $S$ contained in $\tilde{S}$.

Then define the intersection functions $\iota_L : \tilde{S} \times \Gamma \to \{\pm 1, 0\}$ such that

$$\iota_L(S, \gamma) := \begin{cases} 
1 & \text{for a path } \gamma \text{ lying above and outgoing w.r.t. } S \\
-1 & \text{for a path } \gamma \text{ lying below and outgoing w.r.t. } S \\
0 & \text{the path } \gamma \text{ is not outgoing w.r.t. } S
\end{cases}$$

and the intersection functions $\iota_R : \tilde{S} \times \Gamma \to \{\pm 1, 0\}$ such that

$$\iota_R(S, \gamma) := \begin{cases} 
-1 & \text{for a path } \gamma' \text{ lying above and ingoing w.r.t. } S \\
1 & \text{for a path } \gamma' \text{ lying below and ingoing w.r.t. } S \\
0 & \text{the path } \gamma' \text{ is not ingoing w.r.t. } S
\end{cases}$$

whenever $S \in \tilde{S}$ and $\gamma \in \Gamma$.

Define a map $\sigma_L : \tilde{S} \to g$ such that

$$\sigma_L(S) = \sigma_L(S^{-1})$$

whenever $S \in \tilde{S}$ and $S^{-1}$ is the surface $S$ with reversed orientation. Denote the set of such maps by $\tilde{\sigma}_L$. Respectively, the map $\sigma_R : \tilde{S} \to g$ such that

$$\sigma_R(S) = \sigma_R(S^{-1})$$

whenever $S \in \tilde{S}$. Denote the set of such maps by $\tilde{\sigma}_R$. Moreover, there is a map $\sigma_L \times \sigma_R : \tilde{S} \to g \oplus g$ such that

$$(\sigma_L, \sigma_R)(S) = (\sigma_L, \sigma_R)(S^{-1})$$

whenever $S \in \tilde{S}$. Denote the set of such maps by $\tilde{\sigma}$.

Finally, define the **Lie algebra-valued quantum flux set for paths**

$$\mathcal{G}_{\tilde{S}, \Gamma} := \bigcup_{\sigma_L \times \sigma_R \in \tilde{\sigma}_L \times \tilde{\sigma}_R} \left\{(E^L, E^R) \in \text{Map}(\Gamma, g \oplus g) : (E^L, E^R)(\gamma) := (\iota_L(S, \gamma)\sigma_L(S), \iota_R(S, \gamma)\sigma_R(S)) \right\}$$

where $\text{Map}(\Gamma, g \oplus g)$ is the set of all maps from the graph $\Gamma$ to the direct sum $g \oplus g$ of Lie algebras.

Observe that, $(\iota_L \times \iota_R)(S^{-1}, \gamma) = (-\iota_L \times -\iota_R)(S, \gamma)$ holds for every $\gamma \in \Gamma$.

Remark that, the condition $E^L(\gamma) = E^R(\gamma^{-1})$ is not required.

**Example 2.6:** Analyse the following example. Consider a graph $\Gamma$ and two disjoint surface sets $\tilde{S}$ and $\tilde{T}$.
Then the elements of \( g_{\tilde{S},1} \) are for example given by the maps \( E^i_L \times E^i_R \) for \( i = 1, 2 \) such that

\[
\begin{align*}
E_1(\gamma) &:= (E^1_L, E^1_R)(\gamma) = (\iota_L(S_1, \gamma)\sigma_L(S_1), \iota_R(S_1, \gamma)\sigma_R(S_1)) = (X_1, 0) \\
E_2(\gamma) &:= (E^2_L, E^2_R)(\gamma) = (\iota_L(S_2, \gamma)\sigma_L(S_2), \iota_R(S_2, \gamma)\sigma_R(S_2)) = (X_2, 0) \\
E_3(\gamma) &:= (E^3_L, E^3_R)(\gamma) = (\iota_L(S_3, \gamma)\sigma_L(S_3), \iota_R(S_3, \gamma)\sigma_R(S_3)) = (0, -Y_3) \\
E_4(\gamma) &:= (E^4_L, E^4_R)(\gamma) = (\iota_L(S_4, \gamma)\sigma_L(S_4), \iota_R(S_4, \gamma)\sigma_R(S_4)) = (0, Y_4)
\end{align*}
\]

This example shows that, the surfaces \( \{S_1, S_2\} \) are similar, whereas the surfaces \( \{T_1, T_2\} \) produce different signatures for different paths. Moreover, the set of surfaces are chosen such that one component of the direct sum is always zero.

For a particular surface set \( \tilde{S} \) the set

\[
\bigcup_{\sigma_L \times \sigma_R \in \tilde{S}} \bigcup_{S \in \tilde{S}} \{(E^L, E^R) \in \text{Map}(\Gamma, g \oplus g) : (E^L, E^R)(\gamma) := (\iota_L(S, \gamma)\sigma_L(S), 0)\}
\]

is identified with

\[
\bigcup_{\sigma_L \in \tilde{S}} \bigcup_{S \in \tilde{S}} \{E \in \text{Map}(\Gamma, g) : E(\gamma) := \iota_L(S, \gamma)\sigma_L(S)\}
\]

The same is observed for another surface set \( \tilde{T} \) and the set \( g_{\tilde{T}, \Gamma} \) is identifiable with

\[
\bigcup_{\sigma_R \in \tilde{T}} \bigcup_{T \in \tilde{T}} \{E \in \text{Map}(\Gamma, g) : E(\gamma) := \iota_R(T, \gamma)\sigma_R(T)\}
\]

The intersection behaviour of paths and surfaces plays a fundamental role in the definition of the quantum flux operator. There are exceptional configurations of surfaces and paths in a graph. One of them is the following.

**Definition 2.32.** A set \( \tilde{S} \) of \( N \) surfaces has the **simple surface intersection property for a graph** \( \Gamma \) with \( N \) independent edges iff it contains only surfaces, for which each path \( \gamma_i \) of a graph \( \Gamma \) intersects only one surface \( S_i \) only once in the target vertex of the path \( \gamma_i \), the path \( \gamma_i \) lies above and there are no other intersection points of each path \( \gamma_i \) and each surface in \( \tilde{S} \).

**Example 2.7:** Consider the following example.
The sets \{S_9, S_{11}\} or \{S_{10}, S_{12}\} have the simple surface intersection property for the graph \(\Gamma\). Calculate 
\[ E_9(\gamma) = (0, -Y_0), \quad E_{11}(\gamma) = (0, -Y_{11}) \]

In this case the set \(\mathcal{g}_{S,\Gamma}\) reduces to 
\[ \bigcup_{\sigma_R \in \mathcal{g} \cap S} \bigcup_{S \in \mathcal{S}} \left\{ E \in \text{Map}(\Gamma, \mathcal{g}) : E(\gamma) := -\sigma_R(S) \text{ for } \gamma \cap S = t(\gamma) \right\} \]

Notice that, the set \(\Gamma \cap \tilde{S} = \{t(\gamma_i)\}\) for a surface \(S_i \in \tilde{S}\) and \(\gamma_i \cap S_i \cap S_j = \{\emptyset\}\) for a path \(\gamma_i\) in \(\Gamma\) and \(i \neq j\).

On the other hand, the set of surfaces can be such that each path of a graph intersect all surfaces of the set in the same vertex. This contradicts the assumption that each path of a graph intersect only one surface once.

**Definition 2.33.** Let \(\Gamma\) be a graph that contains no loops.

A set \(\tilde{S}\) of surfaces has the same surface intersection property for a graph \(\Gamma\) if each path \(\gamma_i\) in \(\Gamma\) intersects with all surfaces of \(\tilde{S}\) in the same source vertex \(v_i \in V_\Gamma\) \((i = 1, \ldots, N)\), all paths are outgoing and lie below each surface \(S \in \tilde{S}\) and there are no other intersection points of each path \(\gamma_i\) and each surface in \(\tilde{S}\).

Recall the example 2.6. Then the set \(\{S_1, S_2\}\) has the same surface intersection property for the graph \(\Gamma\).

Then the set \(\mathcal{g}_{S,\Gamma}\) reduces to 
\[ \bigcup_{\sigma_L \in \mathcal{g} \cap L} \bigcup_{S \in \mathcal{S}} \left\{ E \in \text{Map}(\Gamma, \mathcal{g}) : E(\gamma) := -\sigma_L(S) \text{ for } \gamma \cap S = s(\gamma) \right\} \]

Notice that, \(\gamma \cap S_1 \cap \ldots \cap S_N = s(\gamma)\) for a path \(\gamma\) in \(\Gamma\), whereas \(\Gamma \cap \tilde{S} = \{s(\gamma_i)\}_{1 \leq i \leq N}\). Clearly, \(\Gamma \cap S_i = s(\gamma_i)\) holds for a surface \(S_i\) in \(\tilde{S}\).

Simply speaking the physical intuition is that, fluxes associated to different surfaces should act on the same path.

Notice that, both properties can be restated for other surface and path configurations. Hence, a surface set can have the simple or same surface intersection property for paths that are outgoing and lie above (or ingoing and below, or outgoing and below). The important fact is related to the question if the intersection vertices are the same for all surfaces or not.

In section 2.1 the concept of finite graph systems has been introduced. The following remark shows that, the properties simply generalises to this new structure.

**Remark 2.34.** A set \(\tilde{S}\) has the same surface intersection property for a finite orientation preserved graph system \(\mathcal{P}_\Gamma\) associated to a graph \(\Gamma\) (with no loops) iff the set \(\tilde{S}\) has the same surface intersection property the graph \(\Gamma\).

A set \(\tilde{S}\) has the simple surface intersection property for a finite orientation preserved graph system \(\mathcal{P}_\Gamma\) associated to a graph \(\Gamma\) if the set \(\tilde{S}\) has the simple surface intersection property for the graph \(\Gamma\).

**Definition 2.35.** Let \(\tilde{S}\) be a surface set and \(\Gamma\) be a graph such that the only intersections of the graph and each surface in \(\tilde{S}\) are contained in the vertex set \(V_\Gamma\).

Then the set of images \(\{E(\gamma) : E \in \mathcal{g}_{S,\Gamma}\}\) of flux maps for a fixed path \(\gamma\) in \(\Gamma\) is denoted by \(\mathcal{g}_{S,\gamma}\).

**Proposition 2.36.** Let \(\tilde{S}\) be a set of surfaces and \(\Gamma\) be a fixed graph (with no loops) such that the set \(\tilde{S}\) has the same surface intersection property for a graph \(\Gamma\). Moreover, let \(\tilde{T}\) be a set of surfaces and \(\Gamma\) be a fixed graph such that the set \(\tilde{T}\) has the simple surface intersection property for a graph \(\Gamma\).

Then the set \(\mathcal{g}_{S,\gamma}\) is equipped with a structure, which is induced from the Lie algebra structure of \(\mathcal{g}\), such that it forms a Lie algebra. The the set \(\mathcal{g}_{T,\gamma}\) is equipped with a structure to form a Lie algebra, too.

---

3Let \(\tilde{S}\) be equal to \(S\). Then notice that the property of all graphs being orientation preserved subgraphs is necessary, since, for a subgraph \(\Gamma' \subseteq \{\gamma'\}\) of \(\Gamma\) the graph \(\{\gamma'^{-1}\}\) is a subgraph of \(\Gamma\), too. Consequently, if there is a surface \(S\) intersecting a path \(\gamma'\) such that \(\gamma'\) is ingoing and lies above, then \(\tilde{S}\) intersects the path \(\gamma'^{-1}\) such that \(\gamma'^{-1}\) is outgoing and lies above. This implies that, the surface \(S\) cannot have the same surface intersection property for each subgraph of \(\Gamma\).
Proof: Step 1: linear space over \( \mathbb{C} \)
Consider a path \( \gamma \) in \( \Gamma \) that lies above and ingoing w.r.t. the surface orientation of each surface \( S \) in \( \hat{S} \) and ingoing and above with respect to \( T \). Then there is a map \( E_S \) such that
\[
E_S(\gamma) = -X
\]
There exists an operation \( + \) given by the map \( s : \mathfrak{g}_{\hat{S}, \gamma} \times \mathfrak{g}_{\hat{S}, \gamma} \to \mathfrak{g}_{\hat{S}, \gamma} \) such that
\[
(E_1^L(\gamma), E_2^L(\gamma)) \mapsto s(E_1^L(\gamma), E_2^L(\gamma)) := E_1^L(\gamma) + E_2^L(\gamma) = -\sigma_L^1(S_1) - \sigma_L^2(S_2) = -\sigma_L^3([S])
\]
since \( \sigma_L^1 \in \sigma_L \) and where \( [S] \) denotes an arbitrary representative of the set \( \hat{S} \). Respectively it is defined
\[
(E_1^L(\gamma), E_2^L(\gamma)) \mapsto s(E_1^L(\gamma), E_2^L(\gamma)) := E_1^L(\gamma) + E_2^L(\gamma) = -\sigma_R^1(T) - \sigma_R^2(T) = -\sigma_R^3(T)
\]
whenever \( \sigma_R^1 \in \sigma_R \) and \( T \in \tilde{T} \). There is an inverse
\[
E(\gamma) - E(\gamma) = X - X = 0
\]
and a null element
\[
E(\gamma) + E_0(\gamma) = X
\]
whenever \( E_0(\gamma) = -\sigma_L(S) = 0 \). Notice the following map
\[\mathfrak{g}_{\hat{S}, \gamma} \times \mathfrak{g}_{\hat{S}, \gamma} \ni (E_1(\gamma), E_2(\gamma)) \mapsto E_1(\gamma) + E_2(\gamma) \in \mathfrak{g}\]
is not considered, since, this map is not well-defined. One can show easily that \( (\mathfrak{g}_{\hat{S}, \gamma}, +) \) is an additive group. The scalar multiplication is defined by
\[
\lambda \cdot E(\gamma) = \lambda X
\]
for all \( \lambda \in \mathbb{C} \) and \( X \in \mathfrak{g} \). Finally, prove that \( (\mathfrak{g}_{\hat{S}, \gamma}, +) \) is a linear space over \( \mathbb{C} \).

Step 2: Lie bracket is defined by the Lie bracket of the Lie algebra \( \mathfrak{g} \) and
\[
[E_1(\gamma), E_2(\gamma)] := [X_1, X_2]
\]
for \( E_1(\gamma), E_2(\gamma) \in \mathfrak{g}_{\hat{S}, \gamma} \) and \( \gamma \in \Gamma \).

\[\blacksquare\]

If a surface set \( \hat{S} \) does not have the same or simple surface intersection property for the graph \( \Gamma \), then the surface set can be decomposed into several sets and the graph \( \Gamma \) can be decomposed into a set of subgraphs. Then for each modified surface set there is a subgraph such that required condition is fulfilled.

Definition 2.37. Let \( \hat{S} \) a set of surfaces and \( \Gamma \) be a fixed graph (with no loops) such that the set \( \hat{S} \) has the same (or simple) surface intersection property for a graph \( \Gamma \).

The universal enveloping Lie algebra of the Lie algebra \( \mathfrak{g}_{\hat{S}, \gamma} \) of fluxes for paths of a path \( \gamma \) in \( \Gamma \) and all surfaces in \( \hat{S} \) is called the universal enveloping flux algebra \( \mathbb{U}_{\hat{S}, \gamma} \) associated to a path and a finite set of surfaces.

Now, the definitions are rewritten for finite orientation preserved graph systems.

Definition 2.38. Let \( \hat{S} \) be a surface set and \( \Gamma \) be a graph such that the only intersections of the graph and each surface in \( \hat{S} \) are contained in the vertex set \( V_\Gamma \). \( \mathcal{P}_\Gamma \) denotes the finite graph system associated to \( \Gamma \). Let \( \mathcal{E} \) be the universal enveloping flux algebra of \( \mathfrak{g} \).

Define the set of Lie algebra-valued quantum fluxes for graphs
\[
\mathfrak{g}_{\hat{S}, \Gamma} := \bigcup_{\sigma_L \times \sigma_R \in \sigma} \bigcup_{S \in \hat{S}} \left\{ E_{S, \Gamma} \in \text{Map}(\mathcal{P}_\Gamma, \bigoplus_{|E_\Gamma|} \mathfrak{g} \oplus \bigoplus_{|E_\Gamma|} \mathfrak{g}) : E_{S, \Gamma} := E_S \times \ldots \times E_S \right\}
\]
where \( E_S(\gamma) := (\iota_L(\gamma, S)\sigma_L(S), \iota_R(\gamma, S)\sigma_R(S)) \), \( E_S \in \mathfrak{g}_{\hat{S}, \Gamma}, S \in \hat{S}, \gamma \in \Gamma \).
Moreover, define
\[
\mathcal{E}_{S, \Gamma} := \bigcup_{\sigma_L \times \sigma_R \in \mathcal{S}} \bigcup_{S \in \mathcal{S}} \left\{ E_{S, \Gamma} \in \text{Map}(\mathcal{P}_T, \bigoplus_{|E_T|} \mathcal{E} \oplus \bigoplus_{|E_T|} \mathcal{E}) : E_{S, \Gamma} := E_S \times \ldots \times E_S \right\}
\]
where \( E_S(\gamma) := (\iota_L(\gamma, S)\sigma_L(S), \iota_R(\gamma, S)\sigma_R(S)) \), \( E_S \in \mathcal{E}_{S, \Gamma}, S \in \mathcal{S}, \gamma \in \Gamma \).

The set of all images of the linear hull of all maps in \( g_{S, \Gamma} \) for a fixed surface set \( \mathcal{S} \) and a fixed graph \( \Gamma \) is denoted by \( \mathfrak{g}_{S, \Gamma} \). The set of all images of the linear hull of all maps in \( g_{\mathcal{S}, \Gamma} \) for a fixed surface set \( \mathcal{S} \) and a fixed subgraph \( \Gamma' \) of \( \Gamma \) is denoted by \( \mathfrak{g}_{\mathcal{S}, \Gamma' \leq \Gamma} \).

Note that, the set of Lie algebra-valued quantum fluxes for graphs is generalised for the inductive limit graph system \( \mathcal{P}_{\Gamma, \infty} \). This follows from the fact that, each element of the inductive limit graph system \( \mathcal{P}_{\Gamma, \infty} \) is a graph.

**Proposition 2.39.** Let \( \mathcal{S} \) be a set of surfaces and \( \mathcal{P}_T^\mathcal{S} \) be a finite orientation preserved graph system such that the set \( \mathcal{S} \) has the same surface intersection property for a graph \( \Gamma \) (with no loops).

The set \( \mathfrak{g}_{\mathcal{S}, \Gamma} \) forms a Lie algebra and is called the *Lie flux algebra associated a graph and a finite surface set*. The universal enveloping flux algebra \( \mathfrak{E}_{\mathcal{S}, \Gamma} \) associated a graph and a finite surface set is the enveloping algebra of \( \mathfrak{g}_{\mathcal{S}, \Gamma} \).

**Proof.** This follows from the observation that, \( \mathfrak{g}_{\mathcal{S}, \Gamma} \) is identified with
\[
\bigcup_{\sigma \in \mathcal{S}} \bigcup_{S \in \mathcal{S}} E_{S, \Gamma} \in \text{Map}(\mathcal{P}_T^\mathcal{S}, \bigoplus_{|E_T|} g) : E_{S, \Gamma} := E_S \times \ldots \times E_S
\]
and the addition operation
\[
E_{S, \Gamma}^1(\Gamma) + E_{S, \Gamma}^2(\Gamma) := (E_{S, \Gamma}^1(\gamma_1) + E_{S, \Gamma}^2(\gamma_2), \ldots, E_{S, \Gamma}^1(\gamma_N) + E_{S, \Gamma}^2(\gamma_N))
\]
\[
= (-\sigma^1_L(S_1) - \sigma^2_L(S_2), \ldots, -\sigma^1_L(S_i) - \sigma^2_L(S_i))
\]
\[
= (E^{\sigma^1_L}_{\mathcal{S}}(\gamma_1), \ldots, E^{\sigma^2_L}_{\mathcal{S}}(\gamma_N))
\]
whenever \( \Gamma := \gamma_1, \ldots, \gamma_N \).

Notice that indeed it is true that,
\[
\mathfrak{g}_{\mathcal{S}, \Gamma} = \mathfrak{g}_{\mathcal{S}, \Gamma}
\]
yields for every \( S_i \in \mathcal{S} \). The more general definition is due to physical arguments.

**Proposition 2.40.** Let \( \mathcal{T} \) be a set of surfaces and \( \mathcal{P}_T^\mathcal{T} \) be a finite orientation preserved graph system such that the set \( \mathcal{T} \) has the simple surface intersection property for \( \Gamma \).

The set \( \mathfrak{g}_{\mathcal{T}, \Gamma} \) forms a Lie algebra.

Notice this follows from the fact that \( \mathfrak{g}_{\mathcal{T}, \Gamma} \) reduces to
\[
\bigcup_{\sigma \in \mathcal{T}} \bigcup_{\mathcal{S}} E_{T, \Gamma} \in \text{Map}(\mathcal{P}_T^\mathcal{T}, \bigoplus_{|E_T|} g) : E_{T, \Gamma} := E_{T_i} \times \ldots \times E_{T_N}
\]
where \( E_{T_i}(\gamma_i) := -\sigma_L(T_i), E_S \in \mathfrak{g}_{\mathcal{S}, \Gamma}, T_i \in \mathcal{T}, \gamma_i \cap T_i = t(\gamma_i), \gamma \in \Gamma \),

since,
\[
E_{S_1, \Gamma}(\Gamma) + \ldots + E_{S_N, \Gamma}(\Gamma) = (E_{T_1}(\gamma_1), 0, \ldots, 0) + (0, E_{T_2}(\gamma_2), 0, \ldots, 0) + \ldots + (0, \ldots, 0, E_{T_N}(\gamma_N))
\]
\[
= (E_{T_1}(\gamma_1), \ldots, E_{T_N}(\gamma_N)) =: E_{T, \Gamma}(\Gamma)
\]
The Lie flux algebra and the universal enveloping flux algebra for the inductive limit graph system \( \mathcal{P}_{\Gamma, \infty} \) and a fixed suitable surface set \( \mathcal{S} \) are denoted by \( \mathfrak{g}_{\mathcal{S}} \) and \( \mathfrak{E}_{\mathcal{S}} \).

Finally assume that \( \mathcal{G}_{\mathcal{S}, \Gamma} \), resp. \( \mathcal{G}_{\mathcal{S}} \), denotes the Lie flux group associated to Lie flux algebra \( \mathfrak{g}_{\mathcal{S}, \Gamma} \), resp. \( \mathfrak{g}_{\mathcal{S}} \).
The discretised and localised quantum flux operator associated to surfaces and graphs

Now consider a restriction of the quantum flux operators to discretised surfaces and graphs. Notice that, the Lie algebra-valued quantum flux operator usually distinguishes between paths, which are lying below, and paths, which are lying above the surface in a surface set. For simplicity in this article the case of paths lying below is considered only. With no doubt the second case can be defined analogously. The discretised surfaces do not allow to distinguish between paths lying above or below with respect to a surface orientation of a surface. Hence in this situation the discretised surface set has to be associated to a set of surfaces with a surface orientation. Summarising the cases below or above are not treated in the context of discretised surfaces. In this way, the intersection functions of definition 2.31 are maps such that \( \iota_L : \tilde{S}_d \times \Gamma \to \{0, -1\} \) and \( \iota_R : \tilde{S}_d \times \Gamma \to \{0, 1\} \).

**Definition 2.41.** Let \( \tilde{S}_d \) be a set of discretised surfaces, which is constructed from a set \( \tilde{S} \) of surfaces, and let \( \Gamma \) be a graph. Let \( \{\Gamma_i\}_{i=1}^{\infty} \) be an inductive family of graphs such that for every graph \( \Gamma_i \), the intersection points of a surface set \( \tilde{S}_d \) and the graph \( \Gamma_i \) are vertices of \( V_{\Gamma_i} \). Denote the set of intersections of a graph \( \Gamma_i \) and a discretised surface set \( \tilde{S}_d \) by \( \iota_S(\Gamma_i) \).

Let \( \Gamma_\infty \) be the inductive limit of a family of graphs \( \{\Gamma_i\} \). Furthermore, assume that, the set \( \tilde{S} \) is chosen such that

(i) for each graph of the family the surface set \( \tilde{S} \) has the same surface intersection property,

(ii) the inductive structure preserves the same surface intersection property\(^4\) for \( \tilde{S} \) and

(iii) each surface in \( \tilde{S} \) intersects the inductive limit \( \Gamma_\infty \) a finite or an infinite number of vertices.

Then \( E_{\tilde{S}_d}(\Gamma)^+ E_{\tilde{S}_d}(\Gamma) \) denote the (Lie algebra-valued) discretised quantum flux operator associated a surface \( \tilde{S}_d \) and a graph \( \Gamma \) such that \( \tilde{S}_d \cap \Gamma \) is a subset of the set of vertices \( V_{\Gamma} \) and \( E_{\tilde{S}_d} \in \mathfrak{g}_{\tilde{S}_d, \Gamma} \).

The (Lie algebra-valued) discretised and localised quantum flux operator \( \tilde{E}_{\tilde{S}_d}(\Gamma_i+1)^+ \tilde{E}_{\tilde{S}_d}(\Gamma_i+1) \) associated a surface \( \tilde{S}_d \) and an inductive family of graphs \( \{\Gamma_i\}_{i=1}^{\infty} \) is defined by the difference operator

\[
\tilde{E}_{\tilde{S}_d}(\Gamma_i+1)^+ \tilde{E}_{\tilde{S}_d}(\Gamma_i+1) := E_{\tilde{S}_d}(\Gamma_i+1)^+ E_{\tilde{S}_d}(\Gamma_i+1) - E_{\tilde{S}_d}(\Gamma_i)^+ E_{\tilde{S}_d}(\Gamma_i)
\]

for \( E_{\tilde{S}_d}(\Gamma_i) \in \mathfrak{g}_{\tilde{S}_d, \Gamma_i} \) and \( E_{\tilde{S}_d}(\Gamma_i+1) \in \mathfrak{g}_{\tilde{S}_d, \Gamma_{i+1}} \) such that

(i) \( \tilde{E}_{\tilde{S}_d}(\Gamma_i+1)^+ \tilde{E}_{\tilde{S}_d}(\Gamma_i+1) \) is non-trivial only for intersections of the surfaces in \( \tilde{S} \) and the graph \( \Gamma_{i+1} \) in vertices contained in the set \( \iota_S(\{\Gamma_i+1\}) \setminus \iota_S(\{\Gamma_i\}) \) and

(ii) \( \tilde{E}_{\tilde{S}_d}(\Gamma_i+1)^+ \tilde{E}_{\tilde{S}_d}(\Gamma_i+1) = E_{\tilde{S}_d}(\Gamma_i+1)^+ E_{\tilde{S}_d}(\Gamma_i+1) \) yields.

The set of such discretised and localised quantum flux operator \( \tilde{E}_{\tilde{S}_d}(\Gamma)^+ \tilde{E}_{\tilde{S}_d}(\Gamma) \) associated a graph \( \Gamma \) is denoted by \( \mathfrak{g}_{\tilde{S}_d, \Gamma}^{loC} \) and called the localised Lie flux algebra associated a discretised surface set and a graph. The set of such discretised and localised quantum flux operator \( \tilde{E}_{\tilde{S}_d}(\Gamma_i+1)^+ \tilde{E}_{\tilde{S}_d}(\Gamma_i+1) \) associated an inductive family of graphs \( \{\Gamma_i\}_{i=1}^{\infty} \) is denoted by \( \mathfrak{g}_{\tilde{S}_d}^{loC} \) and called the localised Lie flux algebra associated to a discretised surface set (and an inductive family of graphs).

The localised enveloping flux algebra \( \mathfrak{e}_{\tilde{S}_d, \Gamma}^{loC} \) associated to a discretised surface set and a graph is given by the enveloping algebra of the localised Lie flux algebra associated to a discretised surface set \( \tilde{S}_d \) and the graph \( \Gamma \).

Finally, the localised enveloping flux algebra \( \mathfrak{e}_{\tilde{S}_d}^{loC} \) associated to a discretised surface set (and an inductive family of graphs) is given by the enveloping algebra of the localised Lie flux algebra associated to a discretised surface set \( \tilde{S}_d \).

If the situation of all paths are ingoing w.r.t all surfaces in a set \( \tilde{S} \), then the localised Lie flux algebra (resp. localised enveloping flux algebra) associated to a discretised surface set \( \tilde{S}_d \) associated to \( \tilde{S} \) and an inductive family of graphs is denoted by \( \mathfrak{g}_{\tilde{S}_d}^{loC} \) (resp. \( \mathfrak{e}_{\tilde{S}_d}^{loC}\)).

Finally assume that, \( \tilde{G}_{\tilde{S}_d, \Gamma} \) (resp. \( \tilde{G}_{\tilde{S}_d} \)) denotes the Lie flux group associated to Lie flux algebra \( \mathfrak{g}_{\tilde{S}_d, \Gamma}^{loC} \) (resp. \( \mathfrak{g}_{\tilde{S}_d}^{loC}\)).

\(^4\)In particular, a graph \( \Gamma' \), which has the same intersection surface property for \( \tilde{S} \), has the same intersection behavior for \( \tilde{S} \) if \( \Gamma' \) is considered as a subgraph of a graph \( \Gamma \), too.
3 The localised holonomy-flux cross-product $\ast$-algebra

3.1 The localised holonomy $\ast$-algebra

The construction of the localised holonomy $C^\ast$-algebra

The construction of the new algebra of quantum configuration variables combines a lot of the structures, which have been presented in [3, 9, 10, 11, 7]. In particular the idea for the definition of the holonomy-flux cross-product $\ast$-algebra [11, Sec.: 3.1], [7, Sec.: 8.4] is used.

Assume that $G$ is a compact connected Lie group, $\Gamma$ be a graph, $\tilde{S}$ a surface set and $\tilde{S}_d$ a discretised surface set (associated to $\tilde{S}$).

The convolution holonomy $\ast$-algebra associated to $\Gamma$ is denoted by $C(\tilde{\mathcal{A}}_d^\Gamma)$ (resp. $C(\tilde{\mathcal{A}}_n^\Gamma)$). This algebra is completed with respect to an appropriate norm to a $C^\ast$-algebra, which is called the non-commutative holonomy $C^\ast$-algebra $C^\ast(\tilde{\mathcal{A}}_d^\Gamma)$ (resp. $C^\ast(\tilde{\mathcal{A}}_n^\Gamma)$) associated to a graph $\Gamma$. Moreover, the $C^\ast$-algebra $C^\ast(\tilde{\mathcal{A}}_d^\Gamma)$ (resp. $C^\ast(\tilde{\mathcal{A}}_n^\Gamma)$) is isomorphic to a infinite matrix $C^\ast$-algebra $M_\infty(\mathbb{C})$. The analytic holonomy $C^\ast$-algebra associated to the graph $\tilde{\Gamma}$ is denoted by $C(\tilde{\mathcal{A}}_{\tilde{\Gamma}})$. Note that, the graph $\tilde{\Gamma}$ is defined such that there are no intersections with elements of $\tilde{S}_d$. Now new $C^\ast$-algebras are constructed from $C^\ast$-tensor product algebras.

**Definition 3.1.** Let $\Gamma$ be a graph, $\tilde{S}$ a surface set and $\tilde{S}_d$ a discretised surface set (associated to $\tilde{S}$). Then denote the subgraph of $\Gamma$ such that, this graph contains all edges of the graph $\Gamma$ that do not intersect with any vertex of the discretised surface set $\tilde{S}_d$, by $\Gamma$.

Define

$$C^\ast(\tilde{\mathcal{A}}_{\tilde{d},\tilde{\Gamma}}) := C^\ast(\tilde{\mathcal{A}}_d^\Gamma) \otimes C^\ast(\tilde{\mathcal{A}}_n^\Gamma) \text{ where}$$

$$C^\ast(\tilde{\mathcal{A}}_d^\Gamma) := \bigotimes_{i \in I} \bigotimes_{k=1, \ldots, N_i^d} C^\ast(\tilde{\mathcal{A}}_{d,\gamma_1,\ldots,\gamma_k})$$

**The localised holonomy $C^\ast$-algebra associated to a graph and a discretised surface set** is given by the tensor product $C^\ast(\tilde{\mathcal{A}}_{\tilde{d},\tilde{\Gamma}}) \otimes C(\tilde{\mathcal{A}}_{\tilde{\Gamma}})$ (with respect to the minimal $C^\ast$-norm).

In this article only certain graphs are studied. These graphs are assumed to decompose into two sets of graphs: one set contains disconnected graphs that contains only paths such that either the source or target vertex is a element of each surface $S_d$ in $\tilde{S}_d$, and the other set of disconnected graphs contains graphs $\Gamma_i$ that contains paths, which does not intersect any point of each discretised surface set $S_d$ in $\tilde{S}_d$. Hence this property generalises to set of graphs. In particular such a decomposition exists for an inductive family of graphs.

**Definition 3.2.** Let $\{\Gamma_i\}$ be an inductive family of graphs, which contain only paths such that either the source or target vertex is an element of each surface $S_d$ in $\tilde{S}_d$. Moreover, let $\{\Gamma_i\}$ be inductive family $\{\Gamma_i\}$ of graphs that contains no paths, which start or end in a vertex contained in any set of the discretised surface set $\tilde{S}_d$.

**There is a increasing family of matrix algebras** $\{C^\ast(\tilde{\mathcal{A}}_d^\Gamma), \beta_{\Gamma_i,\Gamma_{i+1}}\}_{i=1, \ldots, \infty}$ with $\beta_{\Gamma_i,\Gamma_{i+1}}$ unit-preserving $\ast$-homoorphisms such that the union of all matrix algebras is a normed $\ast$-algebra, which can be completed by the minimal tensor product norm to a $C^\ast$-algebra

$$C^\ast(\tilde{\mathcal{A}}_d) := \bigcup_{m=1, \ldots, \infty} C^\ast(\tilde{\mathcal{A}}_d^\Gamma_m)$$

**There is a increasing family of matrix algebras** $\{C^\ast(\tilde{\mathcal{A}}_{\tilde{d},\tilde{\Gamma}}), \beta_{\Delta_{\tilde{\Gamma}}\Gamma_{\tilde{\Gamma}+1}}\}_{i=1, \ldots, \infty}$ with $\beta_{\Delta_{\tilde{\Gamma}}\Gamma_{\tilde{\Gamma}+1}}$ unit-preserving $\ast$-homoorphisms such that the union of all matrix algebras is a normed $\ast$-algebra, which can be completed by the minimal tensor product norm to a $C^\ast$-algebra

$$C^\ast(\tilde{\mathcal{A}}_{\tilde{d}}) := \bigcup_{m=1, \ldots, \infty} C^\ast(\tilde{\mathcal{A}}_{\tilde{d},\Gamma_m})$$

Furthermore, there is an inductive limit $C^\ast$-algebra $C(\tilde{\mathcal{A}}_{\text{loc}})$, which is constructed from an inductive family $\{C(\tilde{\mathcal{A}}_{\Gamma_i}), \beta_{\Gamma_i,\Gamma_{i+1}}\}_{i=1, \ldots, \infty}$ of $C^\ast$-algebras.
In particular, an element of $C^*(\tilde{A}_{d,\Gamma})$ is for example given by

$$f^j_1(\mathfrak{h}_\Gamma(\gamma_{1,1}), \ldots, \mathfrak{h}_\Gamma(\gamma_{N,1})) \otimes f^j_2(\mathfrak{h}_\Gamma(\gamma_{1,1} \circ \gamma_{1,2}), \ldots, \mathfrak{h}_\Gamma(\gamma_{N,1} \circ \gamma_{N,2}))$$

Notice that, for $\Gamma_i \cap \Gamma_j = \emptyset$ for $i \neq j$ then $C^*(\tilde{A}_{d,\Gamma_i \cup \Gamma_j}) = C^*(\tilde{A}_{d,\Gamma_i}) \otimes C^*(\tilde{A}_{d,\Gamma_j})$, $C^*(\tilde{A}_{d,\Gamma})$ is isomorphic to the $C^*$-subalgebra $C^*(\tilde{A}_{d,\Gamma}) \otimes \mathbb{I}_{\Gamma_j}$ of $C^*(\tilde{A}_{d,\Gamma_j}) \otimes C^*(\tilde{A}_{d,\Gamma_j})$ where $\mathbb{I}_{\Gamma_j}$ is the identity operator in $C^*(\tilde{A}_{d,\Gamma_j})$.

**Definition 3.3.** The *localised holonomy* $C^*$-algebra is the $C^*$-tensor product algebra $C(\tilde{A}_{loc}) \otimes C^*(\tilde{A}_d)$ (with respect to the minimal $C^*$-norm) associated to a discretised set of surfaces.

In this definition the notion of localisation is emphasized, since the elements of this new algebra really depend on a chosen discretised surface set associated to a surface set.

**Actions of the group of bisections on the localised holonomy $C^*$-algebra associated to a graph and a discretised surface set**

In this paragraph graph changing operations are studied. First observe that, there are some certain bisections, which map target vertices of certain paths to suitable paths. The set of these bisections in a finite graph system $\mathcal{P}_d^{\tilde{S}_d}$ has been introduced at the end of section 2.2.3 and is denoted by $\mathfrak{B}(\mathcal{P}_d^{\tilde{S}_d})$. Only these bisections restricted to a set $V_d^{\tilde{S}_d}$ are used to define an action of bisections on the localised analytic holonomy $C^*$-algebra associated to a graph and a discretised surface set. The action is for example given by

$$(\zeta_\sigma f_\Gamma)(\mathfrak{h}_\Gamma(\Gamma')) = f_\Gamma(\mathfrak{h}_\Gamma(\Gamma'_\sigma)) \text{ for } \sigma \in \mathfrak{B}(\mathcal{P}_d^{\tilde{S}_d})$$

whenever

- $f_\Gamma \in C^*(\tilde{A}_{d,\Gamma})$,
- $\Gamma' := \{\gamma'_i\}, \Gamma'_\sigma := \{\gamma'_i \circ \sigma(t(\gamma'_i))\}$ are subgraphs of $\Gamma$.

In general the action is defined as follows.

**Lemma 3.4.** There is an action $\alpha$ of the group $\mathfrak{B}(\mathcal{P}_d^{\tilde{S}_d})$ of bisections on the $C^*$-algebra $C^*(\tilde{A}_d)$, which is defined by

$$\zeta_\sigma(f_\Gamma) := f_\Gamma \circ R_\sigma$$

whenever $f_\Gamma \in C^*(\tilde{A}_d)$.

**Proof:** Let $\sigma \in \mathfrak{B}(\mathcal{P}_d^{\tilde{S}_d})$ then $\sigma \mapsto \zeta_\sigma$ is a group homomorphism and

$$\begin{align*}
(\zeta_\sigma_1 \circ \zeta_\sigma_2)(f_\Gamma) &= \zeta_{\sigma_1 \circ \sigma_2}(f_\Gamma) \\
\zeta_\sigma(f_\Gamma)^* &= \zeta_\sigma(f_\Gamma)^*
\end{align*}$$

yields for all $\sigma, \sigma_1, \sigma_2 \in \mathfrak{B}(\mathcal{P}_d^{\tilde{S}_d})$ and $f_\Gamma \in C^*(\tilde{A}_d)$.

Now focus paths, which do not have any intersection with a discretised surface in $\tilde{S}_d$. Then there is an action of $\text{Diff}(\mathcal{P}_d)$ and hence $\mathfrak{B}(\mathcal{P}_d)$ on $\mathcal{C}(\tilde{A}_d)$. This action is a point-norm continuous automorphic action of $\text{Diff}(\mathcal{P}_d)$ on $\mathcal{C}(\tilde{A}_d)$ for every graph $\Gamma$ of the inductive family $\{\Gamma_i\}$ of graphs.

**Derivations defined by the discretised and localised flux operator for surfaces and graphs**

In section 2.3 the discrete and localised flux operator $\tilde{E}_{S_i}(\Gamma_{i+1})^+ \tilde{E}_{S_i}(\Gamma_{i+1})$ has been introduced in definition 2.7.1. The definition of this operator is chosen such that this operator acts non-trivial on elements of $C^*(\tilde{A}_{d,i+1})$ and commute with all elements contained in $C^*(\tilde{A}_d)$.
Definition 3.5. Define the derivation \( \tilde{\delta}_{S_d, \Gamma_j} \) on \( C^*(\mathcal{A}_{T}^d) \) with domain \( \mathcal{D}(\tilde{\delta}_{S_d, \Gamma_{i+1}}) \) by the following commutator

\[
\tilde{\delta}_{S_d, \Gamma_{i+1}}(f_{r_{i+1}}) := [\tilde{E}_{S_d}(\Gamma_{i+1})^+, \tilde{E}_{S_d}(\Gamma_{i+1}), f_{r_{i+1}}]
\]

for a fixed \( \tilde{E}_{S_d}(\Gamma_{i+1})^+ \tilde{E}_{S_d}(\Gamma_{i+1}) \in \tilde{g}^{{\text{loc}}}_{S_d, \Gamma_i} \) and \( f_{r_{i+1}} \in \mathcal{D}(\tilde{\delta}_{S_d, \Gamma_{i+1}}) \).

The domain \( \mathcal{D}(\tilde{\delta}_{S_d, \Gamma_{i+1}}) \) is a \( * \)-subalgebra of \( C^*(\mathcal{A}_{T}^d) \).

Lemma 3.6. The linear operator \( \tilde{\delta}_{S_d, \Gamma_i} \) is a symmetric unbounded \( * \)-derivation with the domain \( \mathcal{D}(\tilde{\delta}_{S_d, \Gamma_i}) \) of the unital \( C^* \)-algebra \( C^*(\mathcal{A}_{T}^d) \). The domain \( \mathcal{D}(\tilde{\delta}_{S_d, \Gamma_i}) \) is a dense \( * \)-subalgebra of \( C^*(\mathcal{A}_{T}^d) \).

Proof: To show that, the domain \( \mathcal{D}(\tilde{\delta}_{S_d, \Gamma_i}) \) is a dense \( * \)-subalgebra of \( C^*(\mathcal{A}_{T}^d) \) recognize that, \( \mathcal{D}(\tilde{\delta}_{S_d, \Gamma_i}) := C^\infty(\mathcal{A}_{T}^d) \) is indeed dense in \( C^*(\mathcal{A}_{T}^d) \).

Corollary 3.7. The limit

\[
\tilde{\delta}_{S_d}(f) := \lim_{j \to \infty} [\tilde{E}_{S_d}(\Gamma_{j+1})^+ \tilde{E}_{S_d}(\Gamma_{j+1}), f]
\]

for every \( f \in \mathcal{D}(\tilde{\delta}_{S_d}) \) and an element \( \tilde{E}_{S_d}(\Gamma_{j+1})^+ \tilde{E}_{S_d}(\Gamma_{j+1}) \in \tilde{g}^{{\text{loc}}}_{S_d, \Gamma_{j+1}} \) for every \( j \), is well-defined in the norm topology. The domain is given by

\[
\mathcal{D}(\tilde{\delta}_{S_d}) = \bigcup_{j=1, \ldots, \infty} \mathcal{D}(\tilde{\delta}_{S_d, \Gamma_j})
\]

Proof: Note that,

\[
[\tilde{E}_{S_d}(\Gamma_{j+1})^+ \tilde{E}_{S_d}(\Gamma_{j+1}), f_{r_{i+1}}] = 0
\]

yields whenever \( P_{r_k} \leq P_{r_{i+1}} \) and \( 0 \leq k \leq j \) and \( f_{r_k} \in C^*(\mathcal{A}_{T}^d) \). Consequently, derive

\[
\tilde{\delta}_{S_d}(f) := \lim_{j \to \infty} [\tilde{E}_{S_d}(\Gamma_{j+1})^+ \tilde{E}_{S_d}(\Gamma_{j+1}), f] = \lim_{j \to \infty} [\tilde{E}_{S_d}(\Gamma_{j+1})^+ \tilde{E}_{S_d}(\Gamma_{j+1}), f_{r_0} \otimes \ldots \otimes f_{r_j} \otimes f_{r_{j+1}}] = \lim_{j \to \infty} [\tilde{E}_{S_d}(\Gamma_{j+1})^+ \tilde{E}_{S_d}(\Gamma_{j+1}), f_{r_{j+1}}] = 0
\]

Redefine the symmetric unbounded \( * \)-derivation for the discretised flux operator \( E_{S_d}(\Gamma_i) \) for a graph \( \Gamma_i \), which is given by

\[
\delta_{S_d, \Gamma_j}(f) = [E_{S_d}(\Gamma_j)^+ E_{S_d}(\Gamma_j), f]
\]

whenever \( f \in \mathcal{D}(\delta_{S_d}) \) and for a fixed \( E_{S_d} \in \mathcal{g}_{S_d, \Gamma_j} \).

In contrast to the property of the \( * \)-derivation of the \( C^* \)-algebra \( C(\mathcal{A}) \) presented in [11, Prop.: 4.7], [4, Prop.: 8.2.19], the \( * \)-derivation of \( C^*(\mathcal{A}^d) \) exists under weaker conditions for the surface set and the directed family of graphs. In the previous construction the set \( \tilde{S} \) of surfaces has to be chosen such that for each graph of the inductive family of graphs \( \{ \Gamma_i \} \) there is only a finite number of intersection vertices with each surface of the set \( \tilde{S} \).

Proposition 3.8. Let \( \tilde{S_d} \) be an arbitrary discretised surface set and \( \{ \Gamma_i \}_{i=1, \ldots, \infty} \) be an inductive family of graphs.

Then the limit

\[
\tilde{\delta}_{S_d}(f) := \lim_{j \to \infty} \delta_{S_d, \Gamma_{j+1}}(f)
\]

is well-defined on \( \mathcal{D}(\delta_{S_d}) \).
whenever $f \in \mathcal{D}(\delta_{S_d})$ exists in norm. The domain of the limit is given by

$$\mathcal{D}(\delta_{S_d}) = \bigcup_{j=1,\ldots,\infty} \mathcal{D}(\delta_{S_d}, r_j)$$

and $\mathcal{D}(\delta_{S_d})$ is a $^\ast$-subalgebra of $C^*(\overline{A}^d)$.

**Proof**: Derive

$$\delta_{S_d}(f) := i \lim_{j \to \infty} \delta_{S_d}(\tau_{r_j}, f) = i \lim_{j \to \infty} \left( \delta_{S_d}(\tau_{r_j}, f) + \delta_{S_d}(f) \right)$$

$$= i \lim_{j \to \infty} [\bar{E}_{S_d}(\Gamma_{j+1})^+ \bar{E}_{S_d}(\Gamma_j), f] + i \lim_{j \to \infty} [E_{S_d}(\Gamma_j)^+ E_{S_d}(\Gamma_j), f]$$

$$= i \lim_{j \to \infty} [\bar{E}_{S_d}(\Gamma_{j+1})^+ \bar{E}_{S_d}(\Gamma_j), f] + \ldots + i \lim_{j \to \infty} [\bar{E}_{S_d}(\Gamma_1)^+ \bar{E}_{S_d}(\Gamma_1), f]$$

$$+ i \lim_{j \to \infty} [E_{S_d}(\Gamma_0)^+ E_{S_d}(\Gamma_0), f]$$

(20)

by using corollary 3.7.

\[ \blacksquare \]

### 3.2 The general localised part of the localised holonomy-flux cross-product $^\ast$-algebra

The construction of the general localised part of the localised holonomy-flux cross-product $^\ast$-algebra

Recall the concept of abstract cross-product algebras, which has been presented by Schmüdgen and Klimyk [13]. This concept has been used in [11, Def.: 3.10], [7, Sec.: 8.2] for the definition of the holonomy-flux cross-product $^\ast$-algebra associated to a surface set. In analogy a similar cross-product $^\ast$-algebra can be defined as follows.

In the following considerations the $^\ast$-algebra $C^*(\overline{A}^d_0)$ (resp. $C^*(\overline{A}^d_t)$) and $C^*(\overline{A}_d, \Gamma)$) has to be restricted to functions in $C^\infty(\overline{A}^d_0)$ (resp. $C^\infty(\overline{A}^d_t)$ and $C^\infty(\overline{A}_d, \Gamma)$). The resulting $^\ast$-subalgebra is denoted by $C^*(\overline{A}^d_0)$ (resp. $C^*(\overline{A}^d_t)$ and $C^*(\overline{A}_d, \Gamma)$) and is called the **localised analytic holonomy $^\ast$-algebra** associated to a graph $\Gamma$ and a discretised surface set $S_d$ again.

To start with a right-invariant flux vector field is defined as follows. For simplicity, the investigations start with a graph $\Gamma$, which contains only one path $\gamma$, and one discretised surface set $S_d$. Clearly, the following definition generalises to graphs and a suitable discretised surface set $S_d$.

**Definition 3.9.** Let the graph $\Gamma$ contain only one path $\gamma$ and $S_d$ be a discrete surface associated to a surface $S$ such that the path lies below and outgoing w.r.t. the surface orientation of $S$. Set $\bar{E}_{S_d}(\Gamma)^+ \bar{E}_{S_d}(\Gamma) =: X_{S_d}^+ X_{S_d}$.

Then the **right-invariant flux vector field** $e^\Gamma$ is defined by

$$[\bar{E}_{S_d}(\Gamma)^+ \bar{E}_{S_d}(\Gamma), f_{\Gamma}] := e^\Gamma(f_{\Gamma})$$

where

$$e^\Gamma(f_{\Gamma})(h_{\Gamma}(\gamma)) = \frac{d}{dt} \bigg|_{t=0} f_{\Gamma}(\exp(t X_{S_d}^+ X_{S_d} h_{\Gamma}(\gamma))) \text{ for } X_{S_d} \in \mathfrak{g}, h_{\Gamma}(\gamma) \in G, t \in \mathbb{R}$$

(21)

whenever $f_{\Gamma} \in C^*(\overline{A}^d_t)$ and $\bar{E}_{S_d}(\Gamma) \in \mathfrak{g}_{S_d, \Gamma}$. Set

$$e^\Gamma(f_{\Gamma})(h_{\Gamma}(\gamma)) = \frac{d}{dt} \bigg|_{t=0} f_{\Gamma}(\exp(-t X_{S_d}^+ X_{S_d} h_{\Gamma}(\gamma))) \text{ for } X_{S_d} \in \mathfrak{g}, h_{\Gamma}(\gamma) \in G, t \in \mathbb{R}$$

(22)

such that

$$[\bar{E}_{S_d}(\Gamma)^+ \bar{E}_{S_d}(\Gamma), f_{\Gamma}] = e^\Gamma(f_{\Gamma})$$

29
The definition of a right invariant vector field is needed to study the following well-defined structure.

**Lemma 3.10.** Let $\tilde{S}_d$ be a set of discretised surfaces, which is constructed from a set $S$ of surfaces, and let $\Gamma$ be a graph. Let $\{\Gamma_i\}_{i=1,\ldots,\infty}$ be an inductive family of graphs such that for every graph $\Gamma_i$ the intersection points of a surface set $\tilde{S}_d$ and the graph $\Gamma_i$ are vertices of $V_i$. Denote the set of intersections of a graph $\Gamma_i$ and a discretised surface set $\tilde{S}_d$ by $i_S(\{\Gamma_i\})$.

Let $\Gamma_\infty$ be the inductive limit of a family of graphs $\{\Gamma_i\}$. Furthermore assume that, the set $\tilde{S}$ is chosen such that

(i) for each graph of the family the surface set $\tilde{S}$ has the same surface intersection property,
(ii) the inductive structure preserves the same surface intersection property for $\tilde{S}$ and $\tilde{S}_d$,
(iii) each surface in $\tilde{S}$ intersects the inductive limit $\Gamma_\infty$ a finite or an infinite number of vertices.

Then $C^*(\tilde{A}_d)$ is a left $E^\text{loc}_{\tilde{S}_d}$-module algebra. The action of $E^\text{loc}_{\tilde{S}_d}$ on $C^*(\tilde{A}_d)$ is given by $\tilde{E}_{\tilde{S}_d}(\Gamma) \triangleright f_r := e^g_r(f_r)$ whenever $E_{\tilde{S}_d}(\Gamma)^+ \tilde{E}_{\tilde{S}_d}(\Gamma) \in E^\text{loc}_{\tilde{S}_d}$ and $f_r \in C^*(\tilde{A}_d)$.

In analogy $C^*(A_d^\Gamma)$ is a right $E^\text{loc}_{\tilde{S}_d^\Gamma}$-module algebra and is defined by right invariant vector fields. Now a construction of a cross-product $^\ast$-algebra is given as follows.

**Definition 3.11.** Let $\tilde{S}_d$ be a set of discretised surfaces associated to a surface set $\tilde{S}$, which has appropriate properties with respect to a graph $\Gamma$ and an inductive family $\{\Gamma_i\}_{i=1,\ldots,\infty}$ of graphs.

The general localised part of the localised holonomy-flux cross-product $^\ast$-algebra for a graph $\Gamma$ and a discretised surface set $\tilde{S}_d$ is given by the left (or right) cross-product $^\ast$-algebra

$$C(\tilde{A}_d^\Gamma) \rtimes_L E^\text{loc}_{\tilde{S}_d^\Gamma} \quad \text{or} \quad C(\tilde{A}_d^\Gamma) \rtimes_R E^\text{loc}_{\tilde{S}_d^\Gamma}$$

which are defined by the vector space $C(\tilde{A}_d^\Gamma) \otimes E^\text{loc}_{\tilde{S}_d^\Gamma}$ with the multiplication given by

$$(f^1 \otimes E^{d^1}_{\tilde{S}_d}(\Gamma)) \cdot (f^2 \otimes E^{d^2}_{\tilde{S}_d}(\Gamma)) := f^1(E^{d^1}_{\tilde{S}_d}(\Gamma) \triangleright f^2) \otimes E^{d^1}_{\tilde{S}_d}(\Gamma) + f^1(f^2 \otimes E^{d^2}_{\tilde{S}_d}(\Gamma)) \cdot E^{d^1}_{\tilde{S}_d}(\Gamma)$$

and the involution

$$(f_r \triangleright E^{d^1}_{\tilde{S}_d}(\Gamma))^* := f_r \triangleright E^{d^1}_{\tilde{S}_d}(\Gamma)^+$$

whenever $E^{d^1}_{\tilde{S}_d}(\Gamma), E^{d^2}_{\tilde{S}_d}(\Gamma) \in E^\text{loc}_{\tilde{S}_d^\Gamma}$ and $f^1, f^2, f_r \in C(\tilde{A}_d^\Gamma)$.

The general localised part of the localised holonomy-flux cross-product $^\ast$-algebra associated to a discretised surface set $\tilde{S}_d$ is given by the left (or right) cross-product $^\ast$-algebra

$$C(\tilde{A}_d) \rtimes_L E^\text{loc}_{\tilde{S}_d} \quad \text{or} \quad C(\tilde{A}_d) \rtimes_R E^\text{loc}_{\tilde{S}_d}$$

which are the inductive limit of the families $\{(C(\tilde{A}_d) \rtimes_L E^\text{loc}_{\tilde{S}_d^\Gamma}, \beta^\Gamma \rtimes \tilde{\beta}^\Gamma_{d^\Gamma} - \beta^\Gamma_{d^\Gamma} \times \tilde{\beta}^\Gamma_{d^\Gamma})\}$ where $\beta^\Gamma_{d^\Gamma} : E^\text{loc}_{\tilde{S}_d^\Gamma} \rightarrow E^\text{loc}_{\tilde{S}_d^\Gamma}$ are suitable unit-preserving $^\ast$-homomorphisms for a suitable set $\tilde{S}_d$ of discretised surfaces that preserve the left (or right) vector field structure.

Summarising the general localised part of the localised holonomy-flux cross-product $^\ast$-algebra is a certain cross-product $^\ast$-algebra, which is defined by the localised analytic holonomy $^\ast$-algebra and the localised enveloping flux algebra associated to a discretised surface set.

A representation of the general localised part of the localised holonomy-flux cross-product $^\ast$-algebra

In [11 Sec.: 4], [7 Sec.: 8.2.3] a certain $^\ast$-representation of a Lie algebra has been studied. This $^\ast$-representation is called the infinitesimal representation of a Lie algebra on a Hilbert space. Similarly the
representation of the general localised part of the localised holonomy-flux cross-product *-algebra is presented as follows.

First in this article the *-representation of the Lie flux algebra $\mathfrak{g}_{\hat{S}_3,\Gamma}$ is implemented by the infinitesimal representation $d\mu$ on the Hilbert space $\mathcal{H}_\Gamma^\mathfrak{g}$, which is given by $L^2(\mathcal{A}_\Gamma^\mathfrak{g},\mu_\mathfrak{g})$. Notice that, the configuration space $\mathcal{A}_\Gamma^\mathfrak{g}$ is equivalent to $G^M$ for a suitable $M\in\mathbb{N}$ and $\mu_\mathfrak{g}$ is the corresponding Haar measure on $G^M$. The infinitesimal representation corresponds to the unitary representation $u$ of the Lie flux group $\hat{G}_{\hat{S}_3,\Gamma}$ in the $C^*$-algebra $C^*(\mathcal{A}_\Gamma)$, i.o.w. $u\in\text{Rep}(\hat{G}_{\hat{S}_3,\Gamma},C^*(\mathcal{A}_\Gamma))$. The *-representation of the general localised part of the localised holonomy-flux cross-product *-algebra is derived from this *-representation.

Summarising the next definition the *-representations of the following algebras:

- the localised analytic holonomy *-algebra $C^*(\mathcal{A}_\Gamma^\mathfrak{g})$,
- the localised enveloping flux algebra $\mathcal{E}_{\mathcal{S}_3,\Gamma}^\mathfrak{g}$ and
- the general localised part of the localised holonomy-flux cross-product *-algebra $C^*(\mathcal{A}_\Gamma^\mathfrak{g})\times_L\mathcal{E}_{\mathcal{S}_3,\Gamma}^\mathfrak{g}$

on the Hilbert space $\mathcal{H}_\Gamma^\mathfrak{g}$ are presented.

**Definition 3.12.** The *-representation of $C^*(\mathcal{A}_\Gamma^\mathfrak{g})$ is defined by

$$\Phi_M(f\Gamma)\psi_T = f\Gamma\psi_T$$

for $f\Gamma \in C^*(\mathcal{A}_\Gamma^\mathfrak{g})$ and $\psi_T \in \mathcal{H}_\Gamma^\mathfrak{g}$

$$\Phi_M(f\Gamma)\psi_T = f^\dagger\psi_T$$

for $f\Gamma \in C^*(\mathcal{A}_\Gamma^\mathfrak{g})$ and $\psi_T \in \mathcal{H}_\Gamma^\mathfrak{g}$

There exists a positive adjoint operator $d\mu(E_{S_3}(\Gamma)^+E_{S_3}(\Gamma))$ or, respectively, the adjoint operator $d\mu(E_{S_3}(\Gamma)^+E_{S_3}(\Gamma))$ on the Hilbert space $\mathcal{H}_\Gamma^\mathfrak{g}$ defined by

$$d\mu(E_{S_3}(\Gamma)^+E_{S_3}(\Gamma))\psi_T := i[E_{S_3}(\Gamma)^+E_{S_3}(\Gamma),\psi_T]$$

for a fixed $E_{S_3}(\Gamma)^+E_{S_3}(\Gamma) \in \mathcal{E}_{\mathcal{S}_3,\Gamma}^\mathfrak{g}$ and $\psi_T \in \mathcal{D}(d\mu(E_{S_3}(\Gamma)^+E_{S_3}(\Gamma)))$

$$d\mu(E_{S_3}(\Gamma)^+E_{S_3}(\Gamma))^+\psi_T := -i[E_{S_3}(\Gamma)^+E_{S_3}(\Gamma),\psi_T]$$

for a fixed $E_{S_3}(\Gamma)^+E_{S_3}(\Gamma) \in \mathcal{E}_{\mathcal{S}_3,\Gamma}^\mathfrak{g}$ and $\psi_T \in \mathcal{D}(d\mu(E_{S_3}(\Gamma)^+E_{S_3}(\Gamma)))$

and $u \in \text{Rep}(\hat{G}_{\hat{S}_3,\Gamma},C^*(\mathcal{A}_\Gamma))$.

The *-representation of the *-algebra $C^*(\mathcal{A}_\Gamma^\mathfrak{g})\times_L\mathcal{E}_{\mathcal{S}_3,\Gamma}^\mathfrak{g}$ on $\mathcal{H}_\Gamma^\mathfrak{g}$ is defined by

$$\hat{\pi}_T(f\Gamma \otimes iE_{S_3}(\Gamma)^+E_{S_3}(\Gamma))\psi_T := \frac{1}{2}i[E_{S_3}(\Gamma)^+E_{S_3}(\Gamma),f\Gamma]\psi_T + \frac{1}{2}i(f\Gamma)[E_{S_3}(\Gamma)^+E_{S_3}(\Gamma),\psi_T]$$

for $f\Gamma \in C^*(\mathcal{A}_\Gamma^\mathfrak{g})$ and for a fixed $E_{S_3}(\Gamma)^+E_{S_3}(\Gamma) \in \mathcal{E}_{\mathcal{S}_3,\Gamma}^\mathfrak{g}$

$$\hat{\pi}_T(f\Gamma \otimes iE_{S_3}(\Gamma)^+E_{S_3}(\Gamma))^+\psi_T := \frac{1}{2}i[E_{S_3}(\Gamma)^+E_{S_3}(\Gamma),f\Gamma]^+\psi_T + \frac{1}{2}i(f\Gamma)[E_{S_3}(\Gamma)^+E_{S_3}(\Gamma),\psi_T]$$

for $f\Gamma \in C^*(\mathcal{A}_\Gamma^\mathfrak{g})$ and for a fixed $E_{S_3}(\Gamma)^+E_{S_3}(\Gamma) \in \mathcal{E}_{\mathcal{S}_3,\Gamma}^\mathfrak{g}$

whenever $\psi_T \in \mathcal{D}(d\mu(E_{S_3}(\Gamma)^+E_{S_3}(\Gamma)))$.

### 3.3 $C^*$-dynamical systems, KMS-states and the localised holonomy-flux cross-product *-algebra

In this section different $C^*$-dynamical systems are constructed from different actions and algebras. The aim is to implement a strongly continuous one-parameter automorphism group such that a modified quantum Hamilton constraint is the generator of this automorphism group. This will be done in several steps. In this section the basic $C^*$-dynamical systems are introduced, which are used in the section 3.4 for the analysis of the modified quantum Hamilton constraint.

First notice the following result. In general, for every $C^*$-algebra $\mathfrak{A}$ and a point norm-continuous automorphic action $\beta$ of $\mathbb{R}$ on $\mathfrak{A}$, there is a set $\mathfrak{A}_\beta$ defined by all element $A \in \mathfrak{A}$ such that $\beta_t(A) = A$ for every $t \in \mathbb{R}$. Then the set $\mathfrak{A}_\beta$ is a norm-dense *-subalgebra of $\mathfrak{A}$. 

31
Set $\mathfrak{h}_T(\Gamma) := \mathfrak{h}_T \in \mathcal{A}_d^\mathfrak{h}$. Let $\tilde{a}_{d,\Gamma}$ be the enveloping Lie algebra of the Lie algebra associated to $\mathcal{A}_d^\mathfrak{h}$. Consider the $C^*$-subalgebra $Z(\mathcal{A}_d^\mathfrak{h})$ of $C^*(\mathcal{A}_d^\mathfrak{h})$, which is generated by all central functions, i.e. all functions $f_T \in C^*(\mathcal{A}_d^\mathfrak{h})$ such that $f_T(\mathfrak{h}_T) = f_T(\mathfrak{g}_T^{-1}\mathfrak{h}_T\mathfrak{g}_T)$ for all $\mathfrak{g}_T \in \mathcal{A}_d^\mathfrak{h}$.

Finally, consider an action $\beta_{d,\Gamma}$ of $\mathbb{R}$ on $C^*(\mathcal{A}_d^\mathfrak{h})$ defined by

$$(\beta_{d,\Gamma}(t)f_T)(\mathfrak{h}_T) := f_T(\exp(-t\tilde{a}_{d,\Gamma})\mathfrak{h}_T, \exp(t\tilde{a}_{d,\Gamma}))$$

and notice that

$$(\beta_{d,\Gamma}(t)f_T)^*(\mathfrak{h}_T) = (\beta_{d,\Gamma}(t)f_T)^*(\mathfrak{h}_T)$$

for a fixed Lie algebra element $a_{d,\Gamma}$ in $\tilde{a}_{d,\Gamma}$ yields. Set $C^*(\mathcal{A}_d^\mathfrak{h})$ be equal to $\mathfrak{a}$. Then $\mathfrak{a}_d^\mathfrak{h}$ is isomorphic to $Z(\mathcal{A}_d^\mathfrak{h})$.

**Proposition 3.13.** The triple $(C^*(\mathcal{A}_d^\mathfrak{h}), \mathbb{R}, \beta_{d,\Gamma})$ is a $C^*$-dynamical system.

This is verified easily, after the following considerations.

Furthermore, there is an action $\tilde{\alpha}_{d,\Gamma}$ of $\mathbb{R}$ on $Z(\mathcal{A}_d^\mathfrak{h})$ defined by

$$(\tilde{\alpha}_{d,\Gamma}(t)f_T)(\mathfrak{h}_T) := f_T(\exp(-t\tilde{a}_{d,\Gamma})\mathfrak{h}_T)$$

and

$$(\tilde{\alpha}_{d,\Gamma}(t)f_T)^*(\mathfrak{h}_T) := (\tilde{\alpha}_{d,\Gamma}(t)f_T)^*(\mathfrak{h}_T)$$

whenever $f_T \in Z(\mathcal{A}_d^\mathfrak{h})$ and $\tilde{a}_{d,\Gamma} \in \tilde{a}_{d,\Gamma}$.

**Proposition 3.14.** The triple $(Z(\mathcal{A}_d^\mathfrak{h}), \mathbb{R}, \tilde{\alpha}_{d,\Gamma})$ is a $C^*$-dynamical system.

**Proof:** Derive

$$(\tilde{\alpha}_{d,\Gamma}(t_1 + t_2)f_T)(\mathfrak{h}_T) = (\tilde{\alpha}_{d,\Gamma}(t_1)f_T)(\mathfrak{h}_T)(\tilde{\alpha}_{d,\Gamma}(t_2)f_T)(\mathfrak{h}_T)$$

and, since $f_T(\mathfrak{h}_T) = f_T(\mathfrak{g}_T^{-1}\mathfrak{h}_T, \mathfrak{g}_T)$ for all $\mathfrak{g}_T \in \mathcal{A}_d^\mathfrak{h}$, it follows that,

$$(\tilde{\alpha}_{d,\Gamma}(t_1)f_T)^*(\mathfrak{h}_T) = (\tilde{\alpha}_{d,\Gamma}(t_1)f_T)^*(\mathfrak{h}_T)$$

yields whenever $t \in \mathbb{R}$ and $f_T \in Z(\mathcal{A}_d^\mathfrak{h})$.

$$(\tilde{\alpha}_{d,\Gamma}(t)(k_T * f_T))(\mathfrak{h}_T) = (k_T * f_T)(\exp(-t\tilde{a}_{d,\Gamma})\mathfrak{h}_T)$$

$$= \int_{\mathcal{A}_d^\mathfrak{h}} d\mu_{d,\Gamma}(\mathfrak{g}_T) k_T(\mathfrak{g}_T, (\Gamma)) f_T(\mathfrak{g}_T, (\Gamma))^{-1} \exp(-t\tilde{a}_{d,\Gamma})\mathfrak{h}_T$$

$$= (\tilde{\alpha}_{d,\Gamma}(t)(k_T * f_T))(\mathfrak{h}_T)$$

whenever $t \in \mathbb{R}$ and $k_T, f_T \in Z(\mathcal{A}_d^\mathfrak{h})$. Moreover, $t \mapsto \tilde{\alpha}_{d,\Gamma}(t)(f_T)$ is point-norm continuous.
Clearly, the same calculations can be done to verify proposition 3.13.

**Proposition 3.15.** There is a state $\hat{\omega}_C^\Gamma$ on $C^*(\hat{A}_\Gamma^d)$ associated to the GNS-triple $(L^2(\hat{A}_\Gamma^d, \mu_{\hat{S}_\Gamma^r}), \Phi_M, \Omega_\Gamma^d)$, which consists of the $^\ast$-representation $\Phi_M$ presented in definition 3.12 the Hilbert space $L^2(\hat{A}_\Gamma^d, \mu_{\hat{S}_\Gamma^r})$ and the cyclic vector $\Omega_\Gamma^d$. The state is given by

$$\hat{\omega}_C^\Gamma(f_R) := \int_{A_r} d\mu_R(h_R) |f_R(h_R)|^2$$

whenever $f_R \in Z(\hat{A}_\Gamma^d)$.

The set $Z(\hat{A}_\Gamma^d)$ contains only entire analytic elements for $\beta_{\alpha_d, \Gamma^r}$.

**Proposition 3.16.** Let $\Gamma_i$ be a graph, $(C^*(\hat{A}_\Gamma^d), \mathbb{R}, \beta_{\alpha_d, \Gamma^r})$ and $(Z(\hat{A}_\Gamma^d), \mathbb{R}, \alpha_{\alpha_d, \Gamma^r})$ be two $C^*$-dynamical systems defined above.

Then the state $\hat{\omega}_C^\Gamma$ is a KMS-state at value $\beta \in \mathbb{R}$ on $C^*(\hat{A}_\Gamma^d)$ or, respectively, on $Z(\hat{A}_\Gamma^d)$.

**Proof:** Calculate for $k_{\Gamma_i}, f_{\Gamma_i} \in Z(\hat{A}_\Gamma^d)$ and $f_{\Gamma_i}(h_{\Gamma_i}) = f_{\Gamma_i}(g_{\Gamma_i}, h_{\Gamma_i})$ for all $g_{\Gamma_i} \in \hat{A}_\Gamma^d$ it is derived that,

$$(k_{\Gamma_i} \ast \hat{\alpha}_{\alpha_d, \Gamma^r}(i\beta)(f_{\Gamma_i}))(h_{\Gamma_i}) = \int_{A_{\Gamma_i}^d} d\mu_{S_d, \Gamma_i}(g_{\Gamma_i}) k_{\Gamma_i}(g_{\Gamma_i}, h_{\Gamma_i}, f_{\Gamma_i}^{-1}(\exp(-i\beta_{\alpha_d, \Gamma^r})) h_{\Gamma_i})$$

is true. Then derive

$$\hat{\omega}_C^\Gamma(f_{\Gamma_i} \ast \hat{\alpha}_{\alpha_d, \Gamma^r}(i\beta)(f_{\Gamma_i}))$$

$$= \int_{A_{\Gamma_i}^d} d\mu_{S_d, \Gamma_i}(h_{\Gamma_i}) (k_{\Gamma_i} \ast \hat{\alpha}_{\alpha_d, \Gamma^r}(i\beta)(f_{\Gamma_i}))(h_{\Gamma_i})^2$$

$$= \int_{A_{\Gamma_i}^d} d\mu_{S_d, \Gamma_i}(h_{\Gamma_i}) \int_{A_{\Gamma_i}^d} d\mu_{S_d, \Gamma_i}(g_{\Gamma_i}) k_{\Gamma_i}(g_{\Gamma_i}, h_{\Gamma_i}, f_{\Gamma_i}^{-1}(\exp(-i\beta_{\alpha_d, \Gamma^r})))^2$$

Clearly, the state $\hat{\omega}_C^\Gamma$ is $\mathbb{R}$-invariant

$$\hat{\omega}_C^\Gamma(f_{\Gamma_i}(t)) = \hat{\omega}_C^\Gamma(\hat{\alpha}_{\alpha_d, \Gamma^r}(t)(f_{\Gamma_i}))$$

for $f_{\Gamma_i} \in Z(\hat{A}_\Gamma^d)$ and all $t \in \mathbb{R}$.

Recall the $^\ast$-derivation $\delta_{S_d, \Gamma^r+1}$ given in definition 3.8 then the state $\hat{\omega}_C^\Gamma$ on $Z(\hat{A}_\Gamma^d)$ satisfies

$$\hat{\omega}_C^{\Gamma+1}(\delta_{S_d, \Gamma^r+1}(f_{\Gamma^r+1})) = \hat{\omega}_C^\Gamma(\delta_{S_d, \Gamma^r}(f_{\Gamma^r+1}) + [\hat{E}_d^{\Gamma^r}(\Gamma^r+1) \hat{E}_d(\Gamma^r+1), f_{\Gamma^r+1}])$$

Hence, the limit state $\hat{\omega}_C$ of the states $\hat{\omega}_C^{\Gamma+1}$ on the $^\ast$-algebra $Z(\hat{A}_\Gamma^d)$ is compatible with the family of $^\ast$-derivations $\{\delta_{S_d, \Gamma^r+1}\}$. Recall the $^\ast$-representations presented in definition 3.12.

33
Corollary 3.17. The state $\hat{\omega}_L^\Gamma$ on $\mathcal{Z}(\hat{A}_d^\Gamma)$ extends to a state $\hat{\omega}_L^\Gamma$ on $\mathcal{Z}(\hat{A}_d^\Gamma) \times_L \mathcal{E}_{S_d,\Gamma}^{\text{loc}}$.

Equivalently, the $^\ast$-representation $\Phi_M$ on $\mathcal{H}_d^\Gamma$ with cyclic vector $\Omega_d^\Gamma$ constructed from $\hat{\omega}_L^\Gamma$ of $\mathcal{Z}(\hat{A}_d^\Gamma)$ extends to a $^\ast$-representation $\hat{\pi}_d^\Gamma$ on $\mathcal{H}_d^\Gamma$ with cyclic vector $\Omega_d^\Gamma$ of $\mathcal{Z}(\hat{A}_d^\Gamma) \times_L \mathcal{E}_{S_d,\Gamma}^{\text{loc}}$.

Proof: Notice that, it is true that $[E_{S_d}(\Gamma_y)^+ E_{S_d}(\Gamma_z), \Omega_d^\Gamma] = 0$ and, hence, derive

$$\hat{\omega}_L^\Gamma(f_{\Gamma} \otimes iE_{S_d}(\Gamma)^+ E_{S_d}(\Gamma)) = \hat{\omega}_L^\Gamma\left(\frac{1}{2} \delta_{S_d,\Gamma}(f_{\Gamma})\right) + (\Omega_d^\Gamma, \frac{1}{2} [E_{S_d}(\Gamma_y)^+ E_{S_d}(\Gamma_z) \Omega_d^\Gamma])$$

whenever $E_{S_d} \in \mathfrak{g}_{S_d,\Gamma}$.

Notice that, the state $\hat{\omega}_L^\Gamma$ on $\mathcal{Z}(\hat{A}_d^\Gamma)$ is not unique. Since, for $K_{\Gamma} \in L^1(\hat{A}_d^\Gamma, \mu_{d,\Gamma})$ there is another state defined by

$$\hat{\omega}_L^\Gamma_{K}(f_{\Gamma}) := \int_{\hat{A}_d^\Gamma} K_{\Gamma}(h_{\Gamma}) d\mu_{A_d^\Gamma}(h_{\Gamma}) |f_{\Gamma}(h_{\Gamma})|^2$$

whenever $f_{\Gamma} \in \mathcal{Z}(\hat{A}_d^\Gamma)$.

There exists a limit state $\hat{\omega}_L$ of the states $\{\hat{\omega}_L^{\Gamma_i+1}\}$ on the $^\ast$-algebra $\mathcal{Z}(\hat{A}_d^{\Gamma_i}) \times_L \mathcal{E}_{S_d}^{\text{loc}}$.

Recall that, there is a group action of $\mathfrak{V}(\mathcal{P}_{\Gamma} S_d)$ on $\mathcal{Z}(\hat{A}_d^{\Gamma_i})$. This action is also action on $\mathcal{Z}(\hat{A}_d^{\Gamma_i}) \times_L \mathcal{E}_{S_d}^{\text{loc}}$, since $E_{S_d}^{\Gamma_i} E_{S_d}(\Gamma) = E_{S_d}^{\Gamma_i} E_{S_d}(\Gamma)$ is true and, hence, $\zeta_{\sigma}(f_{\Gamma} \otimes iE_{S_d}^{\Gamma_i}(\Gamma) E_{S_d}(\Gamma)) = \zeta_{\sigma}(f_{\Gamma} \otimes iE_{S_d}^{\Gamma_i}(\Gamma) E_{S_d}(\Gamma))$ whenever $\sigma \in \mathfrak{V}(\mathcal{P}_{\Gamma} S_d)$ holds.

Definition 3.18. Denote the center of the Lie flux group $\hat{G}_{S_d,\Gamma}$ by $\hat{Z}(\hat{G}_{S_d,\Gamma})$ and the Lie flux algebra associated to $\hat{Z}(\hat{G}_{S_d,\Gamma})$ by $\mathfrak{z}_{S_d,\Gamma}$. Finally, the enveloping algebra of the Lie flux algebra $\mathfrak{z}_{S_d,\Gamma}$ is denoted by $\mathcal{E}_{S_d,\Gamma}$.

Recall that, the space $\hat{A}_d^\Gamma$ is identified with $G^{[\Gamma]}$. The state $\hat{\omega}_L^\Gamma$ on $\mathcal{Z}(\hat{A}_d^\Gamma)$ is already $\text{Diff}(\mathcal{P}_{\Gamma} S_d)$-invariant.

Definition 3.19. Let $\{\Gamma_i\}$ be an inductive family of graphs with inductive limit $\Gamma_{\infty}$, $\hat{S}$ be a set of surfaces and $\hat{S}_d$ a set of discretised surfaces associated to $\hat{S}$ such that the assumptions in definitions 2.41 are satisfied.

Then the localised holonomy-flux cross-product $^\ast$-algebra associated to a discretised surface set $\hat{S}_d$ is given by the following tensor product

$$C(\hat{A}_{\text{loc}}) \otimes \mathcal{Z}(\hat{A}_{\hat{S}_d}) \times_L \mathcal{E}_{\hat{S}_d}$$

The cross-product $^\ast$-algebra $\mathcal{Z}(\hat{A}_{\hat{S}_d}) \times_L \mathcal{E}_{\hat{S}_d}$ is called the localised part of the localised holonomy-flux cross-product $^\ast$-algebra $C(\hat{A}_{\text{loc}}) \otimes \mathcal{Z}(\hat{A}_{\hat{S}_d}) \times_L \mathcal{E}_{\hat{S}_d}$.

Note that, the localised holonomy-flux cross-product $^\ast$-algebra associated to a discretised surface set $\hat{S}_d$ is abbreviated by the term localised holonomy-flux cross-product $^\ast$-algebra for surfaces.

Theorem 3.20. Let $\{\Gamma_i\}$ be an inductive family of graphs with inductive limit $\Gamma_{\infty}$, $\hat{S}$ be a set of surfaces and $\hat{S}_d$ a set of discretised surfaces associated to $\hat{S}$ such that the assumptions in definitions 2.41 are satisfied.

Then there exists a $\text{Diff}(\mathcal{P}_{\Gamma_i} \hat{S}_d)$- and $\text{Diff}(\mathcal{P}_{\Gamma_i})$-invariant state on $C(\hat{A}_{\text{loc}}) \otimes \mathcal{Z}(\hat{A}_{\hat{S}_d}) \times_L \mathcal{E}_{\hat{S}_d}$, which is a product state of the state $\omega_M$ of $C(\hat{A}_{\text{loc}})$ and the state $\hat{\omega}_L$ of $\mathcal{Z}(\hat{A}_{\hat{S}_d}) \times_L \mathcal{E}_{\hat{S}_d}$. The state $\hat{\omega}_L^\Gamma$ is a KMS-state on $\mathcal{Z}(\hat{A}_d^\Gamma)$ at inverse temperature $\beta \in \mathbb{R}$ w.r.t. the automorphism $\alpha_{S_d,\Gamma}$.

34
Summarising a modified holonomy-flux algebra is constructed. The assumption of diffeomorphism invariance of the state space of the modified algebra is relaxed to a surface-preserving graph-diffeomorphism invariance for a finite set $\hat{S}$ of surfaces and an arbitrary fixed graph $\Gamma$.

Finally, if different surface sets are considered, then the following is true. There is a family whenever $f$ for a finite set $\bar{C}$ of the state space of the modified algebra is relaxed to a surface-preserving graph-diffeomorphism invariance. Summarising a modified holonomy-flux algebra is constructed. The assumption of diffeomorphism invariance set $\bar{C}$ then for every surface $S$ the algebra $\bar{Z}$ is of the form $\bar{S}$ such that the assumptions in definition 2.41 are satisfied. Then for every surface $S_1$ in $\bar{S}$ there is a surface $\bar{S}$ in $\bar{S}$ with $S_1 \subset S$ and $S_1^d \subset S^d$. Then it is true that, the algebra $\bar{Z}$ is a subalgebra of $\bar{Z}$ and $\bar{S}$ is not true for the full localised holonomy-flux cross-product $\star$-algebras associated to a graph and a surface set $\hat{S}$.

For two disjoint surface sets $\bar{S}_1$ and $\bar{S}_2$ the elements of the localised holonomy-flux cross-product $\star$-algebras satisfies some relations. But there is no easy locality relation such that two algebra elements commute, i.e., $A \in C(\bar{A}_\Gamma) \otimes \bar{Z}(\bar{S}_1^d) \otimes_L \bar{E}_{\bar{S}_1^d,\Gamma}$ and $B \in C(\bar{A}_\Gamma) \otimes \bar{Z}(\bar{S}_2^d) \otimes_L \bar{E}_{\bar{S}_2^d,\Gamma}$ it is not true that, $[A,B] = 0$ yields. Notice that, the quantum flux operators $E_{\bar{S}_1}^1(\bar{\Gamma}) \in \bar{E}_{\bar{S}_1^d,\Gamma}$ and $E_{\bar{S}_2}^2(\bar{\Gamma}) \in \bar{E}_{\bar{S}_2^d,\Gamma}$ satisfy $[E_{\bar{S}_1}^1(\bar{\Gamma}), E_{\bar{S}_2}^2(\bar{\Gamma})] = 0$.

### 3.4 The quantum constraints and a suggestion for a physical $\star$-algebra

Recall the quantum Hamilton constraint operator defined in [5,7], which is given for example in [13] by the expression

$$Q(C_T(N)) = \sum_{\Delta \in T} \text{tr} \left( (\mathfrak{h}_A(l_\Delta) - \mathfrak{h}_A(l_\Delta)^{-1}) \mathfrak{h}_A(\gamma_\Delta)[\mathfrak{h}_A(\gamma_\Delta)^{-1}, Q(V)] \right)$$

where $\mathfrak{h}_A(l_\Delta)$ denotes a holonomy along a loop $l_\Delta$ in a subset $\Delta$ of a triangulation $T$, $\gamma_\Delta$ denotes a path. Let $\hat{S} := \{\bar{S}_1, \bar{S}_2, \bar{S}_3\}$ be a set of surfaces associated to the triangulation $T$. Then the quantum volume operator $Q(V)$ is defined by

$$Q(V) = \sum_{\gamma_1, \gamma_2, \gamma_3} E_{\bar{S}_1}(\gamma_1)E_{\bar{S}_2}(\gamma_2)E_{\bar{S}_3}(\gamma_3)$$

the sum is over all triples of paths, which are built from three paths that intersects in a common vertex $v$. Consequently, one can localise the quantum volume operator and the quantum Hamilton constraint operator on a set $\bar{S}$ of discretised surfaces and a graph system $P_\Gamma$. The resulting operators are denoted by $Q(C_T(N))_{d,\Gamma}$ or $Q(V)_{d,\Gamma}$ and are called the modified (or discretised) quantum Hamilton constraint or the discretised quantum volume constraint associated to graphs. But the operator $Q(C_T(N))_{d,\Gamma}$ is neither an element of $\bar{Z}(\bar{A}_\Gamma^d)$ nor $C(\bar{A}_{\text{loc}}) \otimes \bar{Z}(\bar{S}_\Gamma^d) \otimes_L \bar{E}_{\bar{S}_\Gamma^d,\Gamma}$.

Consequently, in the following the quantum Hamilton constraint is modified. First notice the quantum Hamilton constraint $\Gamma$ restricted to a graph, which is given by

$$\exp(H_\Gamma) := (\mathfrak{h}_\Gamma(l) - \mathfrak{h}_\Gamma(l)^{-1}) \mathfrak{h}_\Gamma(\gamma)[\mathfrak{h}_\Gamma(\gamma)^{-1}, Q(V)_{d,\Gamma}]$$

whenever $l, \gamma \in \Gamma$. In particular, the quantum Hamilton part $H_{\Gamma,\Gamma}$ restricted to a graph is given by

$$\exp(H_{\Gamma,\Gamma}) := (\mathfrak{h}_\Gamma(l) - \mathfrak{h}_\Gamma(l)^{-1}) \mathfrak{h}_\Gamma(\gamma)$$

whenever $l, \gamma \in \Gamma$. The operator $[\mathfrak{h}_\Gamma(\gamma)^{-1}, Q(V)_{d,\Gamma}]$ is omitted first. Then the quantum Hamilton part is localised such that $H_{\Gamma,\Gamma}$ is an element of the enveloping Lie algebra of the Lie algebra $\bar{A}_{d,\Gamma}$ associated to $\bar{A}_\Gamma^d$.

The quantum Hamilton part $H_{\Gamma,\Gamma}$ defines an action of $\mathbb{R}$ on $\bar{Z}(\bar{A}_\Gamma^d)$ by

$$(\alpha_{H_{\Gamma,\Gamma}}(t) f_{\Gamma})(\mathfrak{h}_{\Gamma}) := f_{\Gamma,\Gamma}(\exp(-t\bar{H}_{\Gamma,\Gamma}^d)H_{\Gamma,\Gamma}^d)\mathfrak{h}_{\Gamma})$$

and

$$(\alpha_{H_{\Gamma,\Gamma}}^d(t) f_{\Gamma})(\mathfrak{h}_{\Gamma}) = (\alpha_{H_{\Gamma,\Gamma}}^d(t) f_{\Gamma})(\mathfrak{h}_{\Gamma})$$

whenever $f_{\Gamma} \in \bar{Z}(\bar{A}_\Gamma^d)$ and $H_{\Gamma,\Gamma}^d H_{\Gamma,\Gamma}^d \in \bar{A}_{d,\Gamma}$ yields.
Proposition 3.21. The triple \((\mathcal{Z}(\hat{A}_G^d), \mathbb{R}, \alpha_{H_{G_r}, p})\) is a \(C^\ast\)-dynamical system.

The state \(\tilde{\omega}_L^\Gamma\) is a KMS-state at value \(\beta \in \mathbb{R}\) on \(\mathcal{Z}(\hat{A}_G^d)\) such that
\[
\tilde{\omega}_L^\Gamma(A \alpha_{H_{G_r}, p}(i\beta)(B)) = \omega_L^\Gamma(BA)
\]
holds for all \(A, B \in \mathcal{Z}(\hat{A}_G^d)\).

Proposition 3.22. Let the triples \((\mathcal{Z}(\hat{A}_G^d), \text{Diff}(\mathcal{P}_d^S), \zeta)\) and \((\mathcal{Z}(\hat{A}_G^d), \mathbb{R}, \alpha_{H_{G_r}, p})\) be \(C^\ast\)-dynamical systems.

Then the automorphisms \(\zeta\) and \(\alpha_{H_{G_r}, p}\) on \(\mathcal{Z}(\hat{A}_G^d)\) do not commute.

Definition 3.23. Denote the center of the compact Lie group \(\hat{A}_G^d\) by \(\hat{Z}_{S_3, 1}\).

The problem in proposition 3.22 is solved, if it is assumed that, \(\exp(i t H_{G_r}) \in \hat{Z}_{S_3, 1}\) holds for all \(t \in \mathbb{R}\).

The state \(\tilde{\omega}_L^\Gamma\) is \(\mathfrak{P}_d^S\)-invariant. Furthermore this state is \(\mathbb{R}\)-invariant for all quantum Hamilton parts \(H_{G_r}\), such that \(\exp(i t H_{G_r}) \in \hat{Z}_{S_3, 1}\) yields for all \(t \in \mathbb{R}\) and \(\Gamma_i\) being a subgraph of \(\Gamma\).

Notice that, \((\alpha_{H_{G_r}, p})(A_r) = A_r\) holds for all \(A_r \in C(\hat{A}_r)\) and
\[
(\alpha_{H_{G_r}, p})(f_r \otimes E_{S_i}^r (\Gamma) E_{S_i}^r (\Gamma)) = (\alpha_{H_{G_r}, p})(f_r) \otimes E_{S_i}^r (\Gamma) E_{S_i}^r (\Gamma)
\]
for all \(f_r \in \mathcal{Z}(\hat{A}_d^d)\) and \(E_{S_i}^r (\Gamma) E_{S_i}^r (\Gamma) \in \mathfrak{S}_{S_r, \Gamma}\). Consequently, \(\alpha_{H_{G_r}, p} \in \text{Aut}(\mathcal{Z}(\hat{A}_G^d) \rtimes \mathbb{C} \mathfrak{S}_{S_3, 1})\).

Theorem 3.24. Let \(\{\Gamma_i\}\) be an inductive family of graphs, \(\bar{S}\) be a set of surfaces and \(\bar{S}_d\) a set of discretised surfaces associated to \(\bar{S}\) such that the assumptions in definition 2.41 are satisfied. For a fixed graph \(\Gamma\) let \((C(\hat{A}_G^d), \text{Diff}(\mathcal{P}_r), \zeta)\) and \((\mathcal{Z}(\hat{A}_G^d), \text{Diff}(\mathcal{P}_r), \zeta)\) be two \(C^\ast\)-dynamical systems.

Moreover, let \(\{H_{\Gamma_i}, p\}\) be a family of quantum Hamilton parts restricted to graphs such that each element \(\exp(i t H_{\Gamma_i}, p) \in \hat{Z}_{S_3, 1}\), for all \(t \in \mathbb{R}\) and all graphs \(\Gamma_i\) being a subgraph of \(\Gamma_i\).

Let \(\{(\mathcal{Z}(\hat{A}_G^d), \mathbb{R}, \alpha_{H_{\Gamma_i}, p})\}\) be a family of \(C^\ast\)-dynamical systems. Finally, let \(\tilde{\omega}_L\) be the limit state on the \(\ast\)-algebra \(\mathcal{Z}(\hat{A}_G^d) \rtimes \mathbb{C} \mathfrak{S}_{S_3, 1}\) of the states \(\{\tilde{\omega}_L^\Gamma\}\) of the families \(\{(\mathcal{Z}(\hat{A}_G^d), \mathbb{R}, \alpha_{H_{\Gamma_i}, p})\}\) of \(\ast\)-algebras. The state \(\tilde{\omega}_L^\Gamma\) is a KMS-state for \(\mathcal{Z}(\hat{A}_G^d)\) at value \(\beta \in \mathbb{R}\) for all \(\alpha_{H_{\Gamma_i}, p}\) and such that
\[
\tilde{\omega}_L^\Gamma \circ \alpha_{H_{\Gamma_i}, p} = \tilde{\omega}_L^\Gamma
\]
for a graph \(\Gamma_i\) and all \(1 \leq i < \infty\).

Then for a fixed graph \(\Gamma\) there exists a \(\text{Diff}(\mathcal{P}_r)\)- and \(\text{Diff}(\mathcal{P}_r)\)-invariant state on \(C(\hat{A}_G^d) \otimes \mathcal{Z}(\hat{A}_G^d) \rtimes \mathbb{C} \mathfrak{S}_{S_3, 1}\), which is a product state on a state \(\omega_M\) of \(C(\hat{A}_G^d)\) and a state \(\tilde{\omega}_L\) of \(\mathcal{Z}(\hat{A}_G^d) \rtimes \mathbb{C} \mathfrak{S}_{S_3, 1}\).

The state on the localised holonomy-flux cross product \(\ast\)-algebra depends on the families of KMS-states and the state \(\omega_M\) of \(C(\hat{A}_G^d)\). Notice that, \(\omega_M\) need not be \(G_{S_3, 1}\)-invariant for any graph \(\Gamma\). This is indeed distinguishing from the results of the analytic holonomy \(\hat{G}^\ast\)-algebra, where the state is required to be invariant. For example refer to [9] Cor.: 3.60 [7] Cor.: 6.4.3]. But since there is no action of the fluxes on this part of the localised holonomy-flux cross-product \(\ast\)-algebra, this invariance is not required.

Contrary to corollary 3.7 consider the following remark.

Remark 3.25. The limit
\[
\delta_{S_3, 1}(f) := i \lim_{j \to \infty} [H_{\Gamma_j}, p H_{\Gamma_j}, p, f]
\]
for every \(f \in \mathcal{D}(\delta_{S_3, 1})\) and every element \(\exp(H_{\Gamma_j}, p H_{\Gamma_j}, p) \in \hat{Z}_{S_3, 1}\) and \(\Gamma_j < \Gamma_k\), \(i, k \in \mathbb{N}\), is not well-defined in the norm topology.
Until now only quantum Hamilton parts restricted to certain subgraphs of a graph are considered. Hence, the full quantum Hamilton part for a family $\{\Gamma_i\}$ of graphs is given by

$$H_P^+ H_P := \lim_{\Gamma_i \to \Gamma = \text{loc}} \sum_{\Gamma_i' \in \mathcal{P}_{\Gamma_i}} H_{\Gamma_i' P}^+ H_{\Gamma_i', P}$$

**Proposition 3.26.** Let $\{\Gamma_i\}$ be an inductive family of graphs, $\hat{S}$ be a set of surfaces and $\hat{S}_d$ a set of discretised surfaces associated to $\hat{S}$ such that the assumptions in definition 2.42 are satisfied.

Moreover, let $\{H_{\Gamma_i', P}\}$ be a family of quantum Hamilton parts restricted to graphs such that each element $\exp(H_{\Gamma_i', P}^+ H_{\Gamma_i', P}) \in \hat{Z}_{\bar{\Gamma}_i, \Gamma_i}$ for all $t \in \mathbb{R}$ and each subgraph $\bar{\Gamma}_i$ of $\Gamma_i$.

Let $\{(\mathcal{Z}(\hat{A}_d^+), \mathbb{R}, \alpha_{H_{\Gamma_i', P}^+ H_{\Gamma_i', P}})\}$ be a family of $C^*$-dynamical systems. Finally, let $\{\hat{\omega}_{\Gamma_i,s}\}$ be a family of states such that $\hat{\omega}_{\Gamma_i,s}$ is a state on the $^*$-algebra $\mathcal{Z}(\hat{A}_d^+) \rtimes_L \mathcal{E}_{\bar{\Gamma}_i, \Gamma_i}$.

Then the limit state $\hat{\omega}_{\Gamma, P}$ on $\mathcal{Z}(\hat{A}_d^+) \rtimes_L \mathcal{E}_{\bar{\Gamma}}$, which is given by

$$\hat{\omega}_{\Gamma, P}(A) := \lim_{\Gamma_i \to \Gamma = \text{loc}} \frac{1}{|\mathcal{P}_{\Gamma_i}|} \sum_{\Gamma_i' \in \mathcal{P}_{\Gamma_i}} \hat{\omega}_{\Gamma_i, s}^\Gamma \left( \alpha_{H_{\Gamma_i', P}^+ H_{\Gamma_i', P}}(t)(A) \right)$$

and where $|\mathcal{P}_{\Gamma_i}|$ denotes the number of subgraphs of a graph $\Gamma_i$, and which is $\mathbb{R}$-invariant w.r.t. the automorphism group $t \mapsto \alpha_{H_{\Gamma_i', P}^+ H_{\Gamma_i', P}}(t)$, for $A \in \mathcal{Z}(\hat{A}_d^+) \rtimes_L \mathcal{E}_{\bar{\Gamma}_i, \Gamma_i}$ does not converge in weak $^*$-topology.

This proposition implies that the one-parameter group $t \mapsto \alpha_{H_{\Gamma_i', P}^+ H_{\Gamma_i', P}}(t)$ of $^*$-automorphisms is not strongly continuous. Consequently, the derivation $\delta_P$ on $\mathcal{Z}(\hat{A}_d^+)$, which is given by

$$\delta_P(f) := \lim_{t \to 0} \frac{1}{t} \left( \alpha_{H_{\Gamma_i', P}^+ H_{\Gamma_i', P}}(t)(f) - f \right) = \lim_{t \to 0} \left( \frac{1}{|\mathcal{P}_{\Gamma_i}|} \right) \left( \sum_{\Gamma_i' \in \mathcal{P}_{\Gamma_i}} \alpha_{H_{\Gamma_i', P}^+ H_{\Gamma_i', P}}(t)(f) - f \right)$$

for $f \in \mathcal{Z}(\hat{A}_d^+)$, is not converging in norm.

Now, recall the operator $[\hbar_A(\gamma)^{-1}, Q(V)_{d, \Gamma}]$, whenever $\gamma \in \Gamma$ and where $Q(V)_{d, \Gamma}$ is sum over finite products of discretised flux operators for a surface $S_d$ and a graph $\Gamma$. Then the quantum Hamilton restricted to a graph contains also elements of $\mathcal{E}_{\bar{\Gamma}_i, \Gamma_i}$.

Consequently define the discretised and localised quantum flux operator associated to a surface $S_d$ and a family $\{\Gamma_i\}$ of graphs by

$$\tilde{E}_{S_d} \hat{E}_{S_d} := \lim_{\Gamma_i \to \Gamma = \text{loc}} \sum_{\Gamma_i' \in \mathcal{P}_{\Gamma_i}} \tilde{E}_{S_d, \bar{\Gamma}_i} \hat{E}_{S_d, \bar{\Gamma}_i}$$

where $\tilde{E}_{S_d, \bar{\Gamma}_i} := E_{S_d}(\bar{\Gamma}_i) \in \mathcal{E}_{\bar{\Gamma}_i, \Gamma_i}$ for every subgraph $\bar{\Gamma}_i$ of $\Gamma_i$.

**Proposition 3.27.** Let $\{\Gamma_i\}$ be an inductive family of graphs, $\hat{S}$ be a set of surfaces and $\hat{S}_d$ a set of discretised surfaces associated to $\hat{S}$ such that the assumptions in definition 2.42 are satisfied.

Let $\{(\mathcal{Z}(\hat{A}_d^+), \mathbb{R}, \alpha_{\tilde{E}_{S_d, \bar{\Gamma}_i} \hat{E}_{S_d, \bar{\Gamma}_i}})\}$ be a family of $C^*$-dynamical systems. Moreover, let $\{\hat{\omega}_{\Gamma_i,s}\}$ be a family of states such that $\hat{\omega}_{\Gamma_i,s}$ is a state on the $^*$-algebra $\mathcal{Z}(\hat{A}_d^+) \rtimes_L \mathcal{E}_{\bar{\Gamma}_i, \Gamma_i}$.

Then the limit state $\hat{\omega}_{\Gamma, E}$ on $\mathcal{Z}(\hat{A}_d^+) \rtimes_L \mathcal{E}_{\bar{\Gamma}}$, which is given by

$$\hat{\omega}_{\Gamma, E}(A) := \lim_{\Gamma_i \to \Gamma = \text{loc}} \frac{1}{|\mathcal{P}_{\Gamma_i}|} \sum_{\Gamma_i' \in \mathcal{P}_{\Gamma_i}} \hat{\omega}_{\Gamma_i, s}^\Gamma \left( \alpha_{\tilde{E}_{S_d, \bar{\Gamma}_i} \hat{E}_{S_d, \bar{\Gamma}_i}}(t)(A) \right)$$

whenever $A \in \mathcal{Z}(\hat{A}_d^+) \rtimes_L \mathcal{E}_{\bar{\Gamma}}$ and where $|\mathcal{P}_{\Gamma_i}|$ denotes the number of subgraphs of a graph $\Gamma_i$. The state $\hat{\omega}_{\Gamma, E}$ is $\mathbb{R}$-invariant w.r.t. the automorphism group $t \mapsto \alpha_{\tilde{E}_{S_d} \hat{E}_{S_d}}(t)$ and converges in weak $^*$-topology.
Proof: Derive
\[
\lim_{\Gamma_i \to \Gamma_\infty} \left| \hat{\omega}_L^\Gamma_i (A) - \frac{1}{|P_{\Gamma_i}|} \sum_{\Gamma_i' \in P_{\Gamma_i}} \hat{\omega}_L^{\Gamma_i'} \left( \alpha_{E_{S_i \setminus \Gamma_0 \setminus \Gamma_i'}} (t)(A) \right) \right| = \left| \hat{\omega}_L^\Gamma_\infty (A) - \hat{\omega}_L^\Gamma_0 \left( \alpha_{E_{S_i \setminus \Gamma_0 \setminus \Gamma_i'}} (t)(A) \right) \right|
= 0
\]

Recall proposition 3.2: Furthermore the last proposition implies that, the derivation \( \delta_E \) on \( \mathcal{Z}(\tilde{A}^{\mathcal{S}_d}) \), which is given by
\[
\delta_E(f) := \lim_{t \to 0} \frac{1}{t} \left( \alpha_{E_{S_i \setminus \Gamma_0 \setminus \Gamma_i'}} (t)(f) - f \right) = \lim_{t \to 0} \frac{1}{t} \lim_{\Gamma_i \to \Gamma_\infty} \left( \sum_{\Gamma_i' \in P_{\Gamma_i}} \alpha_{E_{S_i \setminus \Gamma_0 \setminus \Gamma_i'}} (t)(f) - f \right)
\]
for \( f \in \mathcal{Z}(\tilde{A}^{\mathcal{S}_d}) \), converges in norm.

Problem 3.1: Let \( \{\Gamma_i\} \) be an inductive family of graphs, \( \tilde{S} \) be a set of surfaces and \( \tilde{S}_d \) a set of discretised surfaces associated to \( \tilde{S} \) such that the assumptions in definition 2.41 are satisfied. For a fixed graph \( \Gamma \) let \( (C(\tilde{A}), \mathfrak{B}(P_\Gamma_0), \zeta) \) and \( (\mathcal{Z}(\tilde{A}^{\mathcal{S}_d}), \mathfrak{B}_{\mathcal{S}_d, surf}(P^{S^*_\Gamma_0}), \zeta) \) be two \( C^* \)-dynamical systems.

The discretised quantum volume operator is explicitly defined by
\[
\mathcal{Q}(V^*V)_{d,\Gamma} := \sum_{(\gamma_1, \gamma_2, \gamma_3) \in \{\mathcal{S} \}^3} E_{\mathcal{S}^*_1}(\gamma_3)^+ E_{\mathcal{S}^*_2}(\gamma_2)^+ E_{\mathcal{S}^*_3}(\gamma_1)^+ E_{\mathcal{S}^*_4}(\gamma_1) E_{\mathcal{S}^*_5}(\gamma_2) E_{\mathcal{S}^*_6}(\gamma_3)
\]
such that \( \mathcal{Q}_{d,\Gamma}(V^*V) \in \mathfrak{E}_{\mathcal{S}_d, \Gamma} \). Recall the quantum Hamilton constraint \( H_\Gamma \) restricted to a graph is presented by
\[
\exp(H_\Gamma) := \exp(H_{\Gamma, 0})[h_\Gamma(\gamma), \mathcal{Q}(V^*V)_{d,\Gamma}]
\]
Moreover let \( \{H_\Gamma\} \) be a family of quantum Hamilton constraints restricted to graphs such that each element \( \exp(H_{\Gamma, i}^+ H_{\Gamma, i}) \in C^*(\tilde{A}_d^\mathcal{S}_d) \times \mathfrak{E}_{\mathcal{S}_d, \Gamma_i} \) for all \( \Gamma \in \mathbb{R} \) and all graphs \( \{\Gamma_i\} \) being subgraphs of \( \Gamma_i \).

Recall the family \( \{\hat{\omega}_L^{\Gamma_i}\} \) of states of the family \( \{\mathcal{Z}(\tilde{A}_d^\mathcal{S}_d) \times \mathfrak{E}_{\mathcal{S}_d, \Gamma_i}\} \) of \( * \)-algebras, which are KMS-states for \( \mathcal{Z}(\tilde{A}_d^\mathcal{S}_d) \) at value \( \beta \in \mathbb{R} \) and such that the states satisfy
\[
\begin{align*}
\hat{\omega}_L^{\Gamma_i} \circ \alpha_{H_{\Gamma_i, i}^+ H_{\Gamma_i, i}} & = \hat{\omega}_L^{\Gamma_i} \\
\hat{\omega}_L^{\Gamma_i} \circ \alpha_{H_{\Gamma_i, i}^+ H_{\Gamma_i, i}} & = \hat{\omega}_L^{\Gamma_i} \circ \zeta_0 \circ \alpha_{H_{\Gamma_i, i}^+ H_{\Gamma_i, i}} (t) \\
\hat{\omega}_L^{\Gamma_i} \circ \alpha_{E_{S_{i, \Gamma_i} \setminus \Gamma_0 \setminus \Gamma_i'}} & = \hat{\omega}_L^{\Gamma_i} \\
\hat{\omega}_L^{\Gamma_i} \circ \alpha_{H_{\Gamma_i, i}^+ H_{\Gamma_i, i}} (t) & = \hat{\omega}_L^{\Gamma_i} \circ \alpha_{E_{S_{i, \Gamma_i} \setminus \Gamma_0 \setminus \Gamma_i'}} \circ \alpha_{H_{\Gamma_i, i}^+ H_{\Gamma_i, i}} (t) \\
\hat{\omega}_L^{\Gamma_i} \circ \alpha_{H_{\Gamma_i, i}^+ H_{\Gamma_i, i}} (t) & = \hat{\omega}_L^{\Gamma_i} \circ \alpha_{E_{S_{i, \Gamma_i} \setminus \Gamma_0 \setminus \Gamma_i'}} \circ \alpha_{H_{\Gamma_i, i}^+ H_{\Gamma_i, i}} (t)
\end{align*}
\]
for all \( \sigma \in \text{Diff}(P_{\Gamma_0}^{S^*_i}), t \in \mathbb{R} \), a subgraph \( \Gamma_i \) of \( \Gamma_i \) and all \( 1 \leq i < \infty \).

There is a problem of convergence of the limit state on the localised holonomy-flux cross-product \( * \)-algebra presented in proposition 3.2. Consequently, the limit state \( \hat{\omega}_L \) on \( \mathcal{Z}(\tilde{A}_d^\mathcal{S}_d) \times L \mathfrak{E}_{\mathcal{S}_d, \Gamma_i} \) has to be analysed further. The hope is that for a suitable modified (or localised) quantum Hamilton constraint derived from
\[
\hat{H}^+ \hat{H} := \lim_{N \to \infty} \sum_{i=1}^N H_{\Gamma_i}^+ H_{\Gamma_i} = \lim_{\Gamma_i \to \Gamma_\infty} \sum_{\Gamma_i' \in P_{\Gamma_i}} H_{\Gamma_i'}^+ H_{\Gamma_i'}
\]
the state \( \hat{\omega}_L \) satisfies
\[
\hat{\omega}_L \circ \alpha_{\hat{H}^+ \hat{H}} = \lim_{\Gamma_i \to \Gamma_\infty} \sum_{\Gamma_i' \in P_{\Gamma_i}} \hat{\omega}_L^{\Gamma_i'} \circ \alpha_{H_{\Gamma_i'}^+ H_{\Gamma_i'}} = \hat{\omega}_L
\]
Summarising, in this situation the state \( \hat{\omega}_L \) would be invariant under the automorphisms inherited by the modified quantum Hamilton \( H \), but the state is only invariant under a finite set of exceptional graph-diffeomorphisms. Despite this fact a localised quantum diffeomorphism constraint is defined as follows. First recall the construction presented in [10 Sec.: 5], [7 Sec.: 7.3]. There some certain operators are developed in the situation of \( C^* \)-algebras. Apart from \( C^* \)-properties the following objects can be analysed. Similarly define an operator, which depends on a bisection in \( \mathfrak{B}(\mathcal{P}_\Gamma) \) and which is \( C(\mathcal{A}_\Gamma) \)-valued, and denote this operator by \( D^\Gamma_\Gamma \). The set of all these operators is denoted by \( \mathfrak{D}_{S_s,\Gamma} \). Furthermore there is an operator, which depends on a bisection in \( \mathfrak{B}_{S_s,\surf}(\mathcal{P}_{\Gamma_\Gamma}) \) and which is \( \mathcal{C}(\mathcal{A}_\Gamma) \times \mathcal{C}(\mathcal{A}_\Gamma) \)-valued, and this operator is denoted by \( D^\sigma_{S_s,\Gamma} \). The adjoint operator is denoted by \( D^{\sigma\ast}_{S_s,\Gamma} \). The set of all these operators is denoted by \( \mathfrak{D}_\Gamma \). For each graph \( \Gamma_i \) of a family of graphs there exists a generating system \( \mathfrak{B}_{S_s,\Gamma_i}(\mathcal{P}_{\Gamma_i}) \) of bisections for this graph. Then set

\[
D^\Gamma_{S_s,\Gamma_i} = \sum_{\sigma_1 \in \mathfrak{B}_{S_s,\surf}(\mathcal{P}_{\Gamma_i})} D^{\sigma_1\ast}_{S_s,\Gamma_i} D^{\sigma_2}_{S_s,\Gamma_i}
\]

for every subgraph \( \Gamma' \) of \( \Gamma_i \). The sum over all graphs of a family of graphs defines the **localised quantum diffeomorphism constraint**. The linear hull over all graphs of a family of graphs of all elements of the set \( \mathfrak{D}_{S_s,\Gamma} \), the set \( \mathfrak{D}_\Gamma \) and the set of all quantum Hamilton constraints restricted to a graph \( \Gamma \) forms the \( \ast \)-algebra \( \mathcal{C} \) of quantum constraints. Note that, this algebra is not a subalgebra of the localised holonomy-flux cross-product \( \ast \)-algebra associated to a discretised surface set. Finally, the **modified quantum Master constraint** \( M \) is defined by the sum of the modified quantum Hamilton constraint and the localised quantum diffeomorphism constraint.

The localised holonomy-flux cross-product \( \ast \)-algebra can be enlarged such that this algebra will be a subalgebra. This algebra will be based on the cross-product construction once more and consequently will be called the **localised holonomy-flux-graph-diffeomorphism cross-product** \( \ast \)-algebra associated to a discretised surface set. It will contain all finite graph-diffeomorphisms. Note that, the modified quantum Hamilton constraint is not contained in this algebra, but it will be in a suitable sense be affiliated with. Now, Dirac states and Dirac observables have to be analysed.

Assume that, \( \mathcal{S}_D \) denotes a set of Dirac states on the localised holonomy-flux-graph-diffeomorphism cross-product \( \ast \)-algebra \( \mathfrak{A} \). It is not obvious that Dirac observables can be easily defined, since the set generated by all quantum constraints in \( \mathcal{C} \) defines a closed left and right ideal in \( \mathfrak{A} \). Assume that \( \mathcal{O}_D \) is the algebra of Dirac observables, which is a subalgebra of the localised holonomy-flux-graph-diffeomorphism cross-product \( \ast \)-algebra. Then

\[
\mathcal{O}_D := \{ A \in \mathcal{O}_D : \alpha_M(t)(A) = A, \forall t \in \mathbb{R} \}
\]

defines a **localised \( \ast \)-algebra of complete quantum observables for surfaces**. Hence the localised holonomy-flux-graph-diffeomorphism cross-product \( \ast \)-algebra associated to a discretised surface set is supposed to be a physical algebra in the context of \( \mathfrak{S} \).

Finally, a short remark with respect to \( C^* \)-algebras is stated. The **localised holonomy-flux cross-product \( C^* \)-algebra for surfaces** is constructable as the inductive limit \( C^* \)-algebra of the inductive family of \( C^* \)-algebras \( \{ C(\mathcal{A}_\Gamma) \otimes C(\mathcal{G}_{S_s,\Gamma}) \times \mathcal{A}_\Gamma \} \) for a suitable set \( S_s \) of discretised surfaces associated to a surface set \( \hat{S} \) with appropriate properties with respect to the inductive limit of the family of graphs. The ideas are derived from to the holonomy-flux cross-product \( C^* \)-algebra presented in [10 7]. There it has been also given an enlargement of the holonomy-flux cross-product \( C^* \)-algebra, which contains finite diffeomorphisms. The generators defined by the quantum diffeomorphisms are not contained in this algebra but affiliated with. This idea will be used in a future work for a similar enlargement of the localised holonomy-flux cross-product \( C^* \)-algebra for surfaces. Consequently a physical algebra, which is indeed a \( C^* \)-algebra, can be constructed in this way.
4 Comparison table

A comparison of the localised holonomy-flux cross-product $^\ast$-algebra and the holonomy-flux cross-product $^\ast$-algebra is presented in the next table. Summarising the construction is based on the algebra of continuous functions depending on holonomies along paths, which is a left (or right-) module for the enveloping flux algebra for surfaces. Consequently, certain algebras can be derived as abstract cross-product algebras. The differences appear by the choice of the set of paths, and hence the construction of the quantum configuration space. Therefore different holonomy algebras are considered. In particular the algebras distinguish with respect to the multiplication operation of the elements of these algebras, and their localisation or non-localisation with respect to a set of discretised surfaces associated to surface sets.
Table 1: Comparison of *-algebras

|                  | holonomy-flux algebra                                      | holonomy-flux cross-product algebra                          | localised holonomy-flux cross-product algebra               |
