Giannetti D., Schifani E., Castracani C., Ghizzoni M., Delaiti M., Penner F., Spotti F.A., Mori A., Ioriatti C., Grasso D.A. - Assessing ant diversity in agroecosystems: the case of Italian vineyards of the Adige Valley

Agroecosystems have gained a dominant position on worldwide land-usage, and therefore preserving their biodiversity is crucial for environmental sustainability. Ants are one of the most widespread groups of terrestrial arthropods, and, thanks to their significant diversification, they are considered as a good proxy group for biodiversity monitoring, also in agroecosystems. Vineyards are economically valuable cultures widespread worldwide, and hosting many ant species, that provide meaningful ecosystem services and dissipaters. Despite the important role that ants play in these agroecosystems, ant biodiversity in vineyards is still poorly studied, especially in Italy. In this context, we present a first detailed quantitative and qualitative assessment of the ant fauna of Italian vineyards from the Adige Valley based on pitfall traps data, and discuss the results in comparison with the few other similar assessments from Europe and other continents. We document an assemblage of 22 species (7-16 per orchard), mostly dominated by three disturbance-tolerant species (including an introduced species). Vineyards’ ant faunas appear to be rather heterogeneous worldwide, mainly following local ecological and biogeographical constraints, and the role that most ant species play in these agroecosystems is presently unknown.

KEY WORDS: vines; biodiversity monitoring; myrmecofauna; Prealps.

INTRODUCTION

Since agriculture has become a dominant category of land usage worldwide, crop management practices have become a decisive factor to preserve the environment (Tilman et al., 2001; Green et al., 2005; Tscharnkte et al., 2005; Firbank et al., 2008). Overlooked for decades, insect and arthropod decline and its severe potential outcomes on ecosystems functioning recently attained much attention showing the need for a deeper commitment in the development of effective monitoring systems in contexts with different anthropic impacts (Burgio & Sommaggio, 2007; Campanaro et al., 2011; Burgio et al., 2015; Dirzo et al., 2014; Hallmann et al., 2017; Leather, 2017; Pizzolotto et al., 2018; Homburg et al., 2019). While agricultural transformations may play a key in this process, diversity and distribution of the arthropodofauna in cultivated areas is still insufficiently documented.

Wine grapes (Vitis vinifera L.) are a widespread cultivated species of important economic value, whose cultivated surface is likely to increase in the future due to climate change (Hannah et al., 2013; Moriondo et al., 2013). European vineyards alone cover 3.2 million ha representing 45% of the world’s total areas under vines and 1.8% of the total utilized agricultural area. Over 20% of them is located in Italy (688,000 ha), representing about 5% of the total utilized agricultural surface (SAU) of the country (Eurostat, 2017; Istat, 2019). Under conventional management practices, establishment of viticulture is often associated with notable negative impacts on soil and local biodiversity, and thus may represent a serious conservation threat in certain contexts (Altieri & Nicholls, 2002; Fairbanks et al., 2004; Hilty & Merenlender, 2004; Coulomla et al., 2006; Hilty et al., 2006; Hildenberg & Schmid, 2008; Coll et al., 2011; Lawrence et al., 2011; Rosado et al., 2013). However, implementing correct agro-ecological practices can be an effective way to address some of these issues (Viers et al., 2012): for example, organic viticulture may allow richer communities of organisms to thrive, both within the vineyards themselves and in neighboring forested areas (e.g. Gaigher & Samways, 2010; Coll et al., 2012; Kehinde & Samways, 2014; Caprio et al., 2015; Masoni et al., 2017; Daane et al., 2018).

Due to their high diversity and strong ecological impacts, ants are considered an important group for biodiversity monitoring in both natural and anthropic impacted ecosystems, including agroecosystems (e.g. Peck et al., 1998; De Bruyn et al., 1999; Agosti et al., 2000; Lach et al., 2010; Gibb et al., 2017), where they provide impactful services and dissipaters. For example, they can control other arthropods, fungi or even weeds (e.g. Risch & Carrol, 1982; Baraibar et al., 2011; Offenberg & Damgaard, 2019) and favor foliar uptake of nitrogen (e.g. Pinkalski et al., 2018), but may also favor mutualistic pest species (e.g. Pekas et al., 2010; Calabuig et al., 2013; Dao et al., 2014). As a result, ants can be employed as biocontrol agents in
some cases (e.g. Way & Khoo, 1992; Peng et al., 2010; Choate & Drummond, 2011; Offenberg, 2015; Cstracani et al., 2017; Schifani et al., 2020), but they can be target of control strategies in other situations (e.g. Tollérup et al., 2004; Greenberg et al., 2013). The balance between negative and positive effects of the ant presence in agroecosystems is variable, and it depends on many factors (e.g. Styrsky & Eubanks, 2006). In the last two decades, several studies began to investigate the role of ants in Italian agroecosystems and their possible use as bioindicators (e.g. Cstracani & Mori, 2006; Ottotetti et al., 2008; La Pergola et al., 2008; Santini et al., 2011; Masoni et al., 2017; Campolo et al., 2015; Cstracani et al., 2015; Schifani et al., 2020). However, most contexts of the highly diversified Mediterranean agriculture remain currently unexplored in this sense.

Accounts of the ant fauna inhabiting vineyards are available through scattered checklists from very different geographic regions. For example, ant check-lists in Australian and South American vineyards were provided by Chong et al. (2011) and Rosado et al. (2012, 2013), while in Europe some assessments were provided by Beltra et al. (2017) in Spain, Gonçalves et al. (2017) in Portugal and Masoni et al. (2017) in central Italy (Tuscany region). However, European vineyards are found under several different climatic conditions. Italy offers a great variety of climatic conditions in this sense: on one hand, vineyards can be found under hot temperate and subtropical temperate climate in Sicily, while they are affected by a sub-continental climate in the Prealpine river valleys (Fratianni & Acquotta, 2017). While Masoni et al. (2017) offered a first assessment from an Italian area characterized by a sub coastal temperate climate, we decided to investigate vineyards’ ants at the northernmost latitudes of Italian viticulture, considering that ants colonizing vineyards under a subcontinental climate have never been documented elsewhere in Europe. Therefore, we conducted a first qualitative and quantitative assessment of ant diversity in vineyards from the Prealpine Adige Valley in Italy in order to provide a baseline overview and compare the results to the accounts from other geographic regions.

MATERIALS AND METHODS

A total of 10 vineyards from the Adige Valley in northern Italy (region: Trentino-Alto Adige; cities: Rovereto and Trento), treated under conventional agriculture, were selected for this study (see Table 1).

The vines (Pinot grigio variety) were grown with a straight, single trunk and then trained onto a pergola system (Fig. 1). The vineyard ground was permanently grass covered between the rows while chemical weed control was applied on a 50 cm strip under the vines. Grass was periodically mowed and mulched on place. Pest control was performed with repeated applications of fungicides and one or two insecticide treatments.

Our monitoring program was conducted from June to September 2016 (which is a good coverage of ants’ activity season in the study area), focusing on two rows of each vineyard (each consisting of 16 vines). To obtain data on the arthropodofauna, we relied on pitfall traps (50-ml polypropylene Falcon vials) filled with 30 ml of propylene glycol. In each row, 12 traps were employed at a time: 4 placed on the vines’ branches (B traps), 4 in the soil between two vines (S2 traps) and 4 at 1 m from the vines, between the rows (S1 traps) (Figs. II, III). Traps were replaced every 15 days, resulting in 7 sampling dates (from 07.06.2016 to 07.09.2016). Therefore, a total of 1680 traps were used (12 traps x 2 rows x 10 vineyards x 7 sampling dates).

Table 1 - List of investigated vineyards.

| Site name          | Latitude and longitude | Altitude (m) |
|--------------------|------------------------|--------------|
| A: La Favorita     | 45.862860, 11.002325    | 175          |

Systematic identification was achieved using general dichotomous keys for arthropods and for soil microarthropods (Chinery, 1986; AA VV, 2005). Specimens were recognized at different systematic levels depending on their taxon, but at least at order level. Ants were sorted and identified to species level and identification was achieved using the information provided by Wagner et al. (2017) and Seifert (2018, 2020). Ants from the cryptic Tetramorium caespitum complex were initially not identified during 2016 as the taxonomy of this complex was still unclear (Schlick-Steiner et al., 2006). After Wagner et al. (2017) eventually provided taxonomic keys, only a part of the initial collection still remained in our possession. Since all available specimens were identified as T. immigrans (see Results), we refer as T. cf. immigrans to all the collected specimens from this group.

Species accumulation curves were computed using R 4.0.3 and the specaccum() function of the vegan package (Oksanen et al., 2017; R Core Team, 2021).

RESULTS

A total of 20,284 specimens were retrieved from the traps and they were classified into 19 major groups representing 15 orders of Arachnida, Crustacea, Hexapoda and Myriapoda classes (Table 2).

Among these groups, ants were the most abundant, consisting in 56% of all of the collected specimens (10,501), and the most frequent, found in 73% of the traps, and these differences were averagely maintained through the entire sampling period (Table 2, Figs. IV, V). Ants were represented by 22 species belonging to 16 genera and 3 subfamilies (Table 3).

The most abundant species, *F. cucularia*, *L. niger* and *T. cf. immigens* represented alone over 85% of the collected specimens, and among them *L. niger* was the most abundant during all the sampling dates (Figs VI, VII).
Fig. IV - Frequency of the four main arthropod groups among the traps retrieved in the seven sampling dates.

Fig. V - Arthropod specimens collected per trap during the seven sampling dates divided across the four main arthropod groups.
Table 3 - Ant species collected during the survey.

| Subfamily | Species                          | Occupied sites (N=10) | Tot. Ind. | % Ind. | Branches traps (B) |

Fig. VI - Frequency on traps during the seven sampling dates of the three ant species detected in all orchards.
Fig. VII - Ant specimens collected per trap during the seven sampling dates for the three species detected in all vineyards.

Fig. VIII - Species accumulation curves based on the number of ant species collected with traps placed in different positions. The vertical bars correspond to 30% of the standard error of the estimate.

The S1 and S2 traps yielded a comparable performance in terms of number of captured ant species (Fig. VIII), and together granted the detection of all of the species encountered during this study, while only a subset of 13 species was collected with B traps.

The number of species collected per vineyard varied from 7 to 16, while *F. cunicularia*, *L. niger* and *T. cf. immigrans* were found in every vineyard. Species accumulation curves showed that the sampling effort determined a clear plateau for most vineyards, with the exception of site I (Fig. IX; Table 4).
DISCUSSION

As strongly documented from literature (e.g. AGOSTI et al., 2000; LACH et al., 2010), once again ants proved to be a convenient arthropod group for monitoring programs in agroecosystems, being consistently as the most abundant group in our survey. This study provides one of the few quantitative assessments conducted on the Italian ant fauna. We documented a moderately diverse fauna characterized by a high diversity of Formicinae and Myrmicinae (with a good diversity of Lasius genus, but also multiple species of Formica, Myrmica and Temnothorax genera) and by the notable absence of Dolichoderinae ants. We found an overwhelming prevalence of species characterized by very large distributions in Europe and beyond, only few Mediterranean taxa and no endemisms (JANICKI et al., 2016; GUÉNARD et al., 2017). This picture is not particularly different from that of recent surveys conducted on the Po Plain, but we detected no Eastern-Mediterranean species and even fewer Mediterranean or South European taxa (CASTRACANI et al., 2020). Moreover, it is worth noting that three notoriously disturbance-tolerant species, *F. cunicularia*, *L. niger* and the *T. cf. immigrans* were the most abundant species, as it was observed elsewhere in Northern Italy (CASTRACANI et al., 2020). While *T. immigrans* is probably an introduced species in Italy (CASTRACANI et al., 2020), the numerical dominance of these three species likely reflects their ability to fill empty niches created by human activities (see ARNAN et al., 2018; 2021). Only about half (54%) of the species we recorded was also detected on the vines themselves through the use of traps placed on their branches. Species like *C. aethiops* or *T. italicus*, which habitually visit plants (SEIFERT, 2018; GIANNETTI...
et al., 2019), were probably only encountered on the soil just because of their low abundance. On the other hand, absence on the vines was expected for the social parasites such as the slave-maker *P. rufescens* or the inquiline *S. testaceus*, which are not active foragers. Other species such as *A. subterranea, H. eduardi* or *G. graminicolora* were also not expected to climb into the vines because they usually forage on the soil surface or within the leaf litter (Seifert, 2018; Grasso et al., 2020). While *S. fujii* belongs to the same category (Seifert, 2018), its finding on vines was rather unexpected.

In comparison to the Australian and Brazilian vineyards’ ant faunas, we detected much fewer ant species. Chong et al. (2011) sampled 50 vineyards from different Australian regions, achieving a vast geographic coverage, and detected 147 species, estimating each vineyard to be inhabited by 30-40 species (but recording only 5-24 species in one of the sampled regions). At the same time, Rosado et al. (2012) recorded 72 species in total in Brazil, from 21 to 50 per vineyard. Our numbers are far lower and the most represented genera are different from those detected in these surveys, but this is unsurprising considering the ecological and biogeographical patterns of ant diversity worldwide: ant diversity is notoriously higher in the tropics, where genera that are dominant in the temperate ecozone have a modest presence and vice-versa (e.g., see Janicki et al., 2016; Guénard et al., 2017).

On the other hand, possible comparisons with vineyards of the northern temperate ecosphere, which host more similar faunas, are not particularly numerous. For example, despite several papers dealt with peculiar ant species and their role in North American vineyards (e.g., Klotz et al., 2003; Tollerup et al., 2004; 2007; Daane et al., 2006; 2007; Nondillo et al., 2016; Townsend et al., 2016; Westermann et al., 2016; Cooper et al., 2019), no data on vineyard overall ant diversity are available. In some other cases, an ant species check-list is provided, but it included only species that were observed foraging on the vines (Beltra et al., 2017). However, some interesting comparisons may be made with data published by Gonçalves et al. (2017) from Portugal and Masoni et al. (2017) from Central Italy. The fauna from the Portuguese sites investigated by Gonçalves et al. (2017) comprises 20 species in total, slightly less than ours, but the number of species per site is averagely much higher (15-20) than in our case, and so it is the number of species (9) common to all their 6 investigated vineyards. It is also a very different fauna in both ecological and biogeographic terms, consisting prevalently of species and genera associated with xero-Mediterranean climatic conditions and with a clear Western-Mediterranean characterization (e.g., Cataglyphis spp., West-Mediterranean Camponotus species such as C. cruentatus (Latreille, 1802) and C. sylvaticus (Olivier, 1792), the Iberian sub-endemic Iberoforica genus, Aphaenogaster iberica Emery, 1908 from the xerothermophilous testaceopilosa group, Crematogaster auberti Emery, 1869). On the other hand, Masoni et al. (2017) recorded a similar number of species (19) from 10 vineyards near Florence (Tuscany, Italy), and a slightly smaller number of species per vineyard than us (5-12). The ant assemblages documented by Masoni et al. (2017) present some relevant similarities such as a relatively high Myrmica diversity and the widespread presence of *F. cunicularia* and *M. ibericus*. Concerning the latter species, Masoni et al. (2017) refer to *M. structor* (Latreille, 1798), but Italy most likely only hosts its cryptic sister species *M. ibericus* (Steiner et al., 2018; Schifani et al., 2021). However, there are also relevant differences, as the reduced diversity of Lasius, and, at the same time, the more widespread presence of thermophilous species such as *P. pallidula* and Mediterranean Tapinoma species from the Dolichoderinae subfamily.

The ecological role of the overwhelming majority of ant species that inhabit vineyards across the globe, including of those we detected in our survey, is still virtually unknown. Only three ant species, the worldwide spread invasive Argentine ant Linepithema humile (Mayr, 1868), the South American L. micans (Forel, 1908) and the North American Formica perpilosa Wheeler, W.M., 1913 have been the subject of several studies considering them as significant pests requiring control strategies in vineyards of California and Brazil (Klotz et al., 2003; Tollerup et al., 2004; 2007; Daane et al., 2006; 2007; Saccheti et al., 2009; Nondillo et al., 2016; Westermann et al., 2016; Cooper et al., 2019). On the other hand, another invasive species, the red imported fire ant Solenopsis invicta Buren, 1972, was deemed a positive presence due to its significant predatory action on pest species in Texas’ vineyards (Townsend et al., 2016).

In conclusion, ant communities in agroecosystems are diverse and often species-rich, and documenting their identities is crucial to assess the possible services and dis-services that different species assemblages may yield. While vineyards are worldwide spread, their ant faunas are rather different from place to place according to local climatic and biogeographic factors, so that the few available data do not show clear patterns, which could have originated from strong homogenizing ecological constraints derived from viticulture per se. Further investigation will be required to understand how the fauna of the vineyards from the Adige Valley compares with that of other agroecosystems or natural habitats from the same region and how different management practices may influence it. It will also be important to assess what is the role that different ant species may play in these environments to improve management practices accordingly.

**AUTHORS CONTRIBUTIONS**

Conceptualization: CC, DG, DAG, CI; Data collection: MD, MG, DG, FP; Specimen processing and identification: CC, MG, ES, FAS; Data curation and analysis: CC, ES; Visualization: CC, DG, ES; Writing—original draft preparation: DG, ES; Writing—review and editing: CC, MD, DAG, CI, AM, FP, FAS; Supervision: DAG, CI, AM; Funding acquisition: DAG, CI, AM. All authors have read and agreed to the published version of the manuscript.
FUNDING

This work was supported by the project agreement “Studio delle interazioni tra formiche e coccinelle cotonose della vite (Planococcus ficus) in agroecosistema vigneto del Trentino e loro utilizzo per la messa a punto di innovativi sistemi di monitoraggio dell’infestazione” (2018) between University of Parma and Edmund Mach Foundation and grants from the University of Parma (FIL-2016-17) assigned to DAG and AM. The work also benefited from the equipment and framework of the COMP-HUB Initiative, funded by the “Departments of Excellence” program of the Italian Ministry for Education, University and Research (MIUR, 2018–2022).

ACKNOWLEDGMENTS

We thank all the owners that granted us access to their vineyards: R. Bottura, Cantina Sociale Viticoltori in Avio, Cantina Mori Colli Zagnasca, G. Cristoforetti, M. Lanza, D. Mazzoldi, V. Menolli, F. Polli, N. Tomasi, L. Tisin. We also thank Federico Maioli and Francesca Tuaretta for working with us as a part of their university internship.
