Abstract

Generally speaking, hydraulic control systems can be divided into two different driving concepts. The first one is the well-known valve-controlled system and the second one is the pump-controlled system. The former possesses the feature of fast dynamic response. However, the poor energy-saving performance is its major fault. On the contrary, the pump-controlled hydraulic system has the significant advantage of energy-saving which meets the current demand in modern machine design. In this paper, the simulation analysis using Matlab/Simulink and DSHplus for a newly developed energy-saving hydraulic tube bender is conducted. Instead of the conventional fixed displacement hydraulic pump, the new hydraulic tube bender utilizes an internal gear pump with AC servomotor as its driving power source. In the new energy-saving hydraulic circuit, the use of conventional pressure relief valve is no longer necessary since the demanded flow-rate and pressure output can be precisely obtained by continuously changing the speed of the AC servomotor. In addition, from the simulation results, it is shown that the energy-saving performance of load-sensing control scheme is somewhat better than that of constant pressure control scheme. Furthermore, the simulation results also show that the newly developed hydraulic tube bender can save up to 40\% of energy consumption in a working cycle as compared to the conventional hydraulic tube bender.

1. Introduction

Nowadays, hydraulic systems still play a very important role in modern industry due to the large output force, high power/weight ratio and excellent stiffness. In this paper, a conventional hydraulic tube bender shown in Fig. 1 is chosen for the study of implementing the hydraulic energy-saving design. Figure 2 shows a typical working cycle of the chosen hydraulic tube bender [5]. It is observed that eight sequential steps are required to complete the 90 degrees bending of a straight tube. They are: (A) advancing the main pushing unit, (B) clamping the tube, (C) advancing the bending unit together with auxiliary pushing unit and bending the tube (90 degrees), (D) retracting the main pushing unit, (E) releasing the clamping of tube, (F) retracting the auxiliary pushing unit, (G) removal of tube and (H) retracting the bending unit. Figure 3 shows eight sequential schemes to demonstrate these eight steps. In the hydraulic circuit of a conventional tube bender, a fixed-displacement vane pump is generally utilized as shown in Fig. 4. In addition, a pilot-operated pressure balanced relief valve together with a two-way solenoid operated valve is used as well to construct the unloading circuit. However, the hydraulic supply pressure of the conventional tube bender has to be set at the maximal demanded pressure of 120 bar to ensure the proper function of all eight steps. Thus, from Fig. 2, it is clear that huge energy lost in the working cycle is inevitable since only the step C requires the maximal supply pressure of 120 bar. For the rest seven steps, however, the actually demanded supply pressure is much lower than the maximal pressure of 120 bar. On the other hand, recent performance improvements in the AC servomotor provide a promising alternative to design the energy-saving hydraulic circuit [2, 3, and 4]. In details, the demanded flow-rate and pressure output of the hydraulic pumping unit can be precisely obtained by continuously changing the speed of the AC servomotor. In this paper, therefore, the implementation of
energy-saving design is mainly based on the AC servomotor-controlled scheme. In the following, the proposed energy-saving control scheme is firstly outlined.

Figure 1: A hydraulic tube bender [5].

Figure 2: Demanded pressure in a working cycle.

Figure 3: Eight sequential schemes to demonstrate the eight steps of tube bending.
2. Energy-saving control scheme

In this paper, two closed-loop control schemes using fuzzy sliding-mode controller are adopted and compared. The first one is load-sensing control strategy and the other one is constant pressure control scheme [4]. Figure 5 shows the block diagram of the load-sensing control. A fixed pressure drop, $\Delta P_{set}$, across the control solenoid valve serves as the reference input. The load pressure, $P_{ls}$, is measured by a pressure sensor and fed back to the closed-loop control system to ensure that the supply pressure, $P_s$, can be real-time adjusted according to the variable load pressure. Consequently, the actual pressure drop, $\Delta P = P_s - P_{ls}$, can be maintained as a constant by the closed-loop control. On the other hand, Figure 6 shows the block diagram of constant pressure control. In this configuration, the reference supply pressure input, $P_{set}$, is varied according to the different demanded pressure levels at various steps as shown in Fig. 2. Thus, the reference supply pressure input is actually not a constant and has to be changed at different steps. Besides, it is worth mentioning that the fuzzy sliding-mode scheme is chosen as the closed-loop controller because it provides a dither-like chattering signal. Such a signal is proven to be effective to overcome the nonlinear friction disturbances [1].

The combination of fuzzy-logic-controller with sliding mode controller results in the fuzzy sliding-mode controller. As an example, the constant pressure control scheme combining the fuzzy sliding-mode controller is illustrated as follows. Figure 7 shows the schematic block diagram of the fuzzy sliding-mode controller. The error signal, $e(k)$, and the error signal change, $\Delta e(k)$, are denoted by $x_1$ and $x_2$ respectively, that is

$$x_1 = e(k) = P_{set} - P_s$$

$$x_2 = \Delta e(k) = e(k) - e(k-1)$$
Unlike the conventional controller, there are four procedures involved in the implementation of a fuzzy sliding-mode controller, fuzzification of the input, fuzzy inference based on the knowledge, the defuzzification of the rule-based control signal and the determination of the scaling factors.

2.1. Fuzzification

The proposed fuzzy sliding-mode controller requires only one input signal, $s$, which is exactly the combination of the parameters $x_1$ and $x_2$.

$$s = \lambda x_1 + x_2$$

The usual triangular fuzzy membership functions for the input signal, $s$, and for the output signal, $u$, are utilized. The input signal also represents the switching surface of the sliding mode controller.

2.2. Inference

The inference process consists of nine typical rules driven by the linguistic values of the input signal, $s$. There are:

- If $s$ is very large-positive, then $u$ is very large-positive.
- If $s$ is large-positive, then $u$ is large-positive.
- If $s$ is medium-positive, then $u$ is medium-positive.
- If $s$ is small-positive, then $u$ is small-positive.
- If $s$ is zero, then $u$ is zero.
- If $s$ is small-negative, then $u$ is small-negative.
- If $s$ is medium-negative, then $u$ is medium-negative.
- If $s$ is large-negative, then $u$ is large-negative.
- If $s$ is very large-negative, then $u$ is very large-negative.

2.3. Defuzzification

The defuzzification is to transform control signal into exact control output. In the defuzzification, the method of center of gravity is used.

$$u = \frac{\sum_{i=1}^{n} W_i B_i}{\sum_{i=1}^{n} W_i}$$

2.4. Determination of scaling factors, GS and GU

Before the input signal, $s$, is fed into the fuzzy-sliding mode controller, it has to be multiplied by the scaling factor, GS, so that the product is normalized in the interval $[-1, 1]$. Similarly, the output signal of the fuzzy-sliding mode controller, $u$, is multiplied by the scaling factor, GU, to meet the actual operating voltage range, -10 V to 10 V, of the AC servomotor. It is also worth mentioning that the values of the factors, GS and GU, affect the system response greatly.
3. Modeling, Simulation results and Discussion

In this paper, two commercial software packages, the Matlab/Simulink and DSHplus, are chosen as simulation tools to analyze the energy-saving performance. Firstly, the modeling procedure by Matlab/Simulink will be outlined. The dynamics of the utilized AC servomotor can be simplified as a first-order function. In addition, a simplified model for a typical single-acting hydraulic cylinder is shown in Fig. 8. The volumetric flow-rate output of the hydraulic pump is given by [2]

\[ Q_S = V_p \times (1 - e^{-t/T}) \]  \hspace{1cm} (5)

In practice, the time constant, T, can be derived from the data sheet of the AC servomotor and is estimated to be 50 ms [6].

From continuity equation, the dynamic model for the supply pressure can be simplified as

\[ \frac{dP_s}{dt} = \frac{E_{oil}}{V_{pipe}} (Q_S - Q_a) \]  \hspace{1cm} (6)

where \( Q_a \) denotes the volumetric flow-rate going into the chamber A of cylinder and can be described by

\[ Q_a = BX_v \sqrt{P_S - P_a} \]  \hspace{1cm} (7)

Similarly, the volumetric flow-rate coming out of the chamber B of cylinder can be obtained as

\[ Q_b = BX_v \sqrt{P_b} \]  \hspace{1cm} (8)

Since the switching directional control valve is utilized in the circuit design, the spool displacement, Xv, is set to be the maximal stroke +3 or -3 mm. The flow constant, B, in Eq. (8) can further be expressed as

\[ B = C_a \pi d_v \sqrt{2/\rho} \]  \hspace{1cm} (9)

If the internal and external leakages of the cylinder are both negligible, the simplified dynamic pressure equations for both chambers of the cylinder are

\[ \frac{dP_a}{dt} = \frac{E_{oil}}{V_a + V_{pipe}} (Q_a - A \dot{Y}) \]  \hspace{1cm} (10)
Finally, the equation of motion gives

\[ M \ddot{Y} + b \dot{Y} = A_a P_a - A_b P_b - F_L \]  

(12)

Thus, the MatLab/Simulink model for the single-acting hydraulic cylinder is shown in Fig. 9. Since there are totally five hydraulic cylinders in the conventional tube bender, the whole hydraulic circuit model containing five single-acting hydraulic cylinders built by MatLab/Simulink is shown in Fig. 10. On the other hand, to double check the validity of the above mentioned modeling and simulation, the hydraulic circuit model for the same conventional tube bender by using the second commercial software package DSHplus is established and shown in Fig. 11. Figure 12 shows the simulation displacements of the main pushing cylinder by two different software packages respectively. Similarly, two calculated actuating pressure curves of the main pushing cylinder are also depicted in Fig. 13. Obviously, from Figures 12 and 13, the calculated cylinder displacements as well as actuating pressure curves derived from MatLab/Simulink and DSHplus respectively are almost identical. It can therefore be verified that the modeling procedure and simulation results by MatLab/Simulink are reliable and can be used for further energy-saving analysis.

It is worth mentioning that the block diagram shown in Fig. 11 is actually an open loop control scheme. It is necessary to incorporate the proposed fuzzy sliding-mode controller into the control structure and form a closed-loop control block diagram. In addition, two proposed control schemes, the constant pressure control and load-sensing control, have also to be implemented. Thus, based on the simplified block diagrams shown in Figures 5 and 6, two comprehensive closed-loop control block diagrams can be obtained as shown in Figures 14 and 15 respectively. In the following, the control performances of these two closed-loop control schemes will be discussed and compared.

After adequate simulations, all important data and information of the whole tube bender system, like the pressure and flow-rate etc., can be obtained. The power consumption of the pumping unit can easily be calculated by the following equation (13).

\[ P_{pump} = \frac{P_s \times Q_s}{600} \]  

(13)

Figure 9: MatLab/SimuLink model for the single-acting hydraulic cylinder.
Figure 10: MatLab/Simulink model for the conventional

Figure 11: Hydraulic circuit model built by DSHplus for conventional tube bender.
As an illustrated example, the simulation results of supplied actuating pressure and volumetric flow-rate by load-sensing control for the main pushing cylinder are shown in Fig. 16, where the pressure drop, $\Delta P_{\text{set}}$, is set to be 3 bar. It is noticeable that both the pressure and flow-rate curves for the advance and retraction of the main pushing cylinder are depicted. In addition, Figure 17 shows the similar simulation results by constant pressure control scheme, where the reference supply pressure input, $P_{\text{set}}$, is set to be 90 bar according to the demanded pressure level at step A shown in Fig. 2. Comparing Fig. 16 and Fig. 17, it is actually not easy to tell the differences of the pressure and volumetric flow-rate signals during the advance and retraction phases of the main pushing cylinder. However, if Eq. (13) and appropriate numerical calculations are applied to evaluate the power consumption, the difference of driving power between two utilized closed-loop control strategies for the main pushing cylinder in one working cycle is more obvious as shown in Fig. 18.

It is worth mentioning that the energy-saving analysis using DSHplus is not executed in this paper because the proposed fuzzy sliding-mode controller is not available in the current library of the commercial software package DSHplus.

Table 1 shows the comparisons of overall energy consumption of pumping unit between the conventional and newly designed energy-saving hydraulic tube bender. It is observed that the energy-saving performance of constant pressure control scheme is somewhat better than that of load-sensing control scheme. Furthermore, the simulation results also show that the newly designed hydraulic tube bender can save up to 40% of energy consumption in a
working cycle as compared to the conventional hydraulic tube bender. These results prove the validity of the proposed energy-saving hydraulic circuit design as well as the effectiveness of proposed closed-loop control schemes.

4. Conclusions

In this paper, a new energy-saving hydraulic tube bender is successfully designed based on the simulation analysis using Matlab/Simulink and DSHplus. The introduction of the additional commercial software package DSHplus is merely to verify the validity of proposed modeling procedure and simulation results. In addition, three conclusions may also be drawn from this research.

(1) The simulation results derived from Matlab/Simulink and DSHplus respectively are nearly identical. It can therefore be verified that the modeling procedure and simulation results by Matlab/Simulink are reliable and can be used for further energy-saving analysis.

(2) Simulation results show that the newly designed hydraulic tube bender can save up to 40% of energy consumption in a working cycle as compared to the conventional hydraulic tube bender. This result not only shows the potential of energy-saving design but also encourages the future real implementation of the new tube bender.

(3) The energy-saving performance of load-sensing control scheme is somewhat better than that of constant pressure control scheme. Besides, the former utilized only one pressure sensor while the latter requires two pressure sensors to calculate the actual pressure drop. Therefore, the better choice would be undoubtedly the constant pressure control scheme which will be suggested to be implemented in the future real layout of the new hydraulic tube bender.

| Item | Step | Conventional | Load-sensing control | Const. pressure control |
|------|------|--------------|----------------------|------------------------|
|      | P₀(bar) | Q₀(1/min) | P_pump(kW) | P₀(bar) | Q₀(1/min) | P_pump(kW) | P₀(bar) | Q₀(1/min) | P_pump(kW) |
| A    | 119.5 | 40.4 | 8.05 | 89.51 | 31.81 | 2.85 | 89.6 | 32.56 | 2.92 |
