Water photolysis effect on the long-term stability of a fiber optic hydrogen sensor with Pt/WO₃

Xuexiang Zhong¹, Minghong Yang¹,², Chujia Huang¹, Gaopeng Wang¹, Jixiang Dai¹ & Wei Bai¹

One of the technological challenges for hydrogen sensors is long-term stability and reliability. In this article, the UV-light irradiation was introduced into the hydrogen sensing process based on water photolysis effect of Pt/WO₃. Ascribing to that, the fiber optic hydrogen sensor with Pt/WO₃ nanosheets as the sensing element was demonstrated with significantly improved performance of stability. Under UV irradiation, the hydrogen sensor exhibits higher sensitivity and resolution together with a smaller error range than that without UV irradiation. The enhanced performance could be attributed to the effective decomposition of water produced in the hydrogen sensing process due to the water photolysis effect of Pt/WO₃. The influence of the water on stability was evaluated using experimental results, and the UV irradiation to remove water was analysed by theoretical and FT-IR spectra. This work provides a new strategy of UV-light irradiation to promote the long-term stability of hydrogen sensor using Pt/WO₃ as the sensing element.

With the increasing depletion of coal, oil and other fossil fuels, the development and utilization of new energy has become more important. As is well known, hydrogen is a clean and renewable energy that can be obtained from a wide variety of sources. Due to its status as the smallest molecule, hydrogen can easily leak in the processes of production, transportation, storage and utilization, and due to its flammability, it may explode strongly when its concentration is in a certain value (4–75%). For this reason, it is extremely important to explore the hydrogen sensors with reliable performance. Compared with conventional hydrogen sensors based on electrical characteristics, the fiber optic hydrogen sensor features excellent characteristics, including intrinsic safety, anti-electromagnetic interference and miniature design. Presently, there are many types of fiber optic hydrogen sensors, such as the interferometric sensor¹², micro-mirror sensor³–⁵, evanescent sensor⁶–¹⁰ and fiber Bragg grating (FBG) sensor¹¹–¹⁶. The FBG hydrogen sensor is especially suitable for distributed measurement and temperature compensation due to its wavelength multiplexing capability. Since the FBG hydrogen sensor is based on wavelength modulation, it can eliminate the influence of light power fluctuations and radically improve the anti-interference ability and stability (stable sensitivity during service period) of the sensor.

Tungsten trioxide (WO₃) has drawn great research interest due to its special characteristics, including its capabilities of photocatalysis, and electrocatalysis, gasochromic and field-emission properties¹⁷–²⁰. WO₃ is an excellent metal oxide material for hydrogen gas sensing because of its chemical stability and gasochromic properties²⁰,²¹. However, pure WO₃ suffers from low sensitivity and a lack of selectivity. Doping with a noble metal, such as Au, Pt or Pd, is an effective means to enhance the detection of specific gases, as these metal catalysts increase the rate of interaction differently for different gases⁴,⁵,¹⁰,¹²,²². Among these metal catalysts, Pt is the most effective catalyst for sensing H₂, and effectively increases the response and selectivity towards H₂. Due to its fast response and high sensitivity, hydrogen sensors based on WO₃ doped with Pt (Pt/WO₃) are of intense interests and have been investigated extensively¹²,¹⁵,¹⁶,²¹,²³. However, like most hydrogen sensors, degradation is still a severe problem for its application. Therefore, factors affecting the stability of the hydrogen sensor have also been widely investigated, such as water content²⁴–²⁶, catalyst poisoning²³, and phase transition²⁷. Among these factors, water content is regarded as an important factor in the long-term stability since water may cover the active Pt surface, resulting in catalyst poisoning and poor stability of the sensor²⁵,²⁸. Water can also decrease the sensitivity of the FBG sensors

which is based on temperature sensing, because water can absorb the heat that is generated by the exothermic reaction between Pt/WO3 and H2.

To improve the long-term stability and sensitivity of the fiber optic FBG hydrogen sensors, in this article, an UV-light irradiation strategy was introduced into the hydrogen sensing process based on the water photolysis effect of Pt/WO3. To the best of our knowledge, while hydrogen sensors based on WO3 gasochromism have been developed and fabricated, there have rarely been theoretical or experimental investigations of hydrogen sensors based on the both gasochromic and water photolysis properties of Pt/WO3. Through continual and systematic experimental tests over 3 months, the hydrogen sensor under UV irradiation exhibits significantly improved long-term stability, and the removal of water under UV irradiation was investigated and demonstrated through FT-IR measurement. The hydrogen sensing principle based on the gasochromism and water photolysis of Pt/WO3 is discussed.

Results and Discussion
Pt/WO3 nanosheets were synthesized by a hydrothermal method followed by annealing. Figure 1(a) shows the XRD pattern of the Pt/WO3 nanosheets. The diffraction peaks agree with the monoclinic phase of WO3 with lattice parameters of a = 7.3 Å, b = 7.53 Å and c = 7.68 Å (JCPDS No. 01-072-1465). In addition, there are three
diffraction peaks at 20 = 39.82°, 46.31° and 67.50°, corresponding to the (111), (200) and (220) planes of the cubic phase of Pt (JCPDS No. 00-004-0802), respectively. The morphologies of Pt/WO3 are shown in Fig. 1(b), which exhibits that the WO3 was mainly composed of uniform nanosheets of approximately 430 nm × 780 nm, and the thickness is in the range of 50–90 nm. The morphology of the WO3 (Fig. S2), shows no significant change after Pt covering.

To obtain further insights into the morphology and structure of the Pt/WO3 nanosheets, TEM and HRTEM analysis were performed and the results are shown in Figs 1(c,d) and S2. It is clearly observed that the Pt particles effectively covered on the surface of WO3, and the particles size of the Pt is approximately 5–10 nm, which results in the weak peaks of Pt shown in the XRD pattern. The HRTEM image of the Pt/WO3 nanosheets shows the typical WO3 and Pt lattice fringes. The contact between the WO3 and Pt called ohmic contact, will facilitate electron transfer from the Pt to the WO3 during the photoexcitation, resulting in enhanced charge separation and photocatalytic efficiency. The periodic fringe spacings of ~3.7 and ~2.3 Å agree well with the interplanar spacing of the (020) plane of monoclinic WO3 and the (111) plane of cubic Pt, respectively. The selected-area electron diffraction (SAED) pattern (Fig. 1(e)) reveals the crystalline nature of the Pt/WO3 nanosheets, as also indicated by their XRD result. To obtain the surface chemical composition and state of the WO3 nanosheets, we performed high-resolution XPS analysis. The XPS spectra of Pt/WO3 are presented in Fig. 1(f) and (g). In the W4f XPS spectrum, the only pair of peaks located at 35.5 and 37.7 eV corresponds to the W4f7/2 and W4f5/2 of WO3. In the Pt4f levels of the samples, the strong doublet decomposition peaks at 71.1 and 74.5 eV could be assigned to metallic Pt, while the weak doublet decomposition peaks at 71.7 and 75.3 eV were corresponded to Pt(II) oxide, such as PtO2. The peak area of metallic Pt was much larger than that of the Pt(II) oxide, which indicated that most of the Pt was in the metallic state.

The sensing probe was placed in a sealed chamber for the hydrogen sensing performance calibration. Hydrogen gas at various concentrations was injected into the sealed chamber, and the shifted FBG wavelengths were recorded. The experimental data were fitted by Equation (7) and the linearity was greater than 0.99 (Fig. S3). Subsequently, the cycling stability of the coatings under two different hydrogen sensing process (with and without UV irradiation) was compared. At room temperature, hydrogen concentration was controlled from low to high by a flowmeter and the characteristics of the sensor probes with and without UV irradiation were tested once every two days. To verify the water effect on the sensing stability, experiments were conducted for 40 cycles. The experimental result of the stability test is shown in Fig. 2. 40 cycles were plotted to determine the stability. From Fig. 2(a) and (b), it can be found that in the case of UV irradiation, the cycle stability is better than that without UV irradiation. The error bars for 95% confidence band in Fig. 2(c) and (d) represent the range that were obtained for each sensor after forty cycles. As shown in Fig. 2(c) and (d), it can be concluded that the FBB characteristic wavelength shift with (without) UV irradiation reaches 380 pm (270 pm) at hydrogen concentration of 15000 ppm, which means the average H2 sensitivity is 0.023 pm/ppm (0.018 pm/ppm). Given the resolution of the fiber optic spectrometer is 1 pm, the equivalent H2 concentration resolution of the sensor is calculated to be 43.5 pm (56 ppm). And the greatest discrepancy of the sensor in the relative wavelength shift is ±16 pm, which corresponds to ±41.99 ppm (±888.9 ppm) of hydrogen concentration. The minimum error of sensor in the relative wavelength shift is ±0.025 pm (±0.04 pm) which corresponds to ±1.1 ppm (±2.2 ppm) of hydrogen concentration.

From the comparison, it can be concluded that the sensitivity, resolution and stability of the sensing probe with UV irradiation are higher than that without UV irradiation. These performance properties were attributed to the water decomposition on the surface of the Pt/WO3 by UV irradiation. Figure 2(e) displays the response time of the Pt/WO3 with UV irradiation under different H2 concentrations. It can be deduced that the response time is approximately 60s and the recovery time is less than 150s. The sensor thus presents a good response at room temperature.

The wavelength shifts of the proposed sensor with UV irradiation under different H2 levels in both the ascending and descending condition are shown in Fig. 2(f). It is clear that the two curves are well consistent with each other at various H2 concentrations. However, a small of discrepancy can be seen, and this discrepancy increases with the H2 concentration. The greatest discrepancy was found to be ±5 pm, which is reasonable compared with the greatest discrepancy in Fig. 2(d). It should be noted that the time interval between the 35th and 36th hydrogen detection is over one month, which indicates that the sensor shows excellent reversibility and stability.

To explain the water generation process and understand the water decomposition under UV irradiation during the sensing process, a mechanism based on gasochromic and photocatalytic process is proposed and shown in Fig. 3. In a system containing WO3 and Pt, since the work function of Pt (5.1 eV) is smaller than that of WO3 (5.7 eV), a deflexion of the energy band of WO3 occurs due to the effect of the ohmic contact (Fig. S4). Consequently, Pt exhibits an excess positive charge, while WO3 accumulates excess e−. When H2 is injected into the chamber, Pt dissociates the adsorbed H2 molecules into ions and traps the produced electrons (e−) as an electron pool due to the deflexed energy band. Meanwhile, the WO3 is transformed to unstable compounds WO3·xH2O under the environment of H+. Subsequently, the color of the WO3 changes to blue. This is the coloration process of WO3 and the reaction can be expressed as the following equation:

\[
\text{H}_2 \xrightarrow{\text{Pt}} 2\text{H}^+ + 2e^-
\]

\[
\text{WO}_3 + 2x\text{H}^+ \rightarrow \text{WO}_{3-x} \cdot x\text{H}_2\text{O} + 2\text{h}^+
\]
Figure 2. Sensitivity curve for different H₂ concentrations (a) without UV irradiation; and (b) with UV irradiation; (c) error analysis of (a); (d) error analysis of (b); (e) time response of sensor in (b); (f) wavelength shifts of (b) under different H₂ concentration in both ascending and descending conditions.

Figure 3. Schematic illustration of Pt/WO₃ (a) react with H₂ and O₂; (b) UV water photolysis.
can be oxidized into WO$_3$. This is the bleaching process of WO$_3$ and the reaction can be expressed as the following equation:

$$\text{O}_2 + e^-_{\text{Pt}} \rightarrow O_2^-$$  \hspace{1cm} (3)

$$\text{WO}_3 \cdot x \cdot \text{H}_2\text{O} + \frac{x}{2} h^+ + \frac{x}{2} O_2 \rightarrow \text{WO}_3 + x\text{H}_2\text{O}$$  \hspace{1cm} (4)

When UV light is irradiated (hv) onto the Pt/WO$_3$ system, electrons ($e^-$) are generated in the conduction band (CB) and holes ($h^+$) are generated in the valence band (VB). These photo-induced holes likely remained in the VB of WO$_3$, whereas electrons are trapped in the CB of Pt, resulting in an efficient space separation of photo-induced charge carriers. The holes stored in the VB of the WO$_3$ are used for splitting H$_2$O molecule in the air near the surface of the WO$_3$ into H$^+$ and O$_2$, and the produced H$^+$ is then transferred to the surface of the Pt and reduced to H$_2$ by absorbing e$^-$. The major steps in this mechanism under UV light irradiation are summarized in the following reactions$^{29,36}$:

$$\text{H}_2\text{O} + 2h^+ \rightarrow 2\text{H}^+ + \frac{1}{2} O_2$$  \hspace{1cm} (5)

$$2\text{H}^+ + 2e^-_{\text{Pt}} \rightarrow \text{H}_2$$  \hspace{1cm} (6)

To verify the water photolysis effect of the UV irradiation on the decomposition of water, the sample reacted with H$_2$ was characterized by FT-IR after irradiated by UV and heated at 120 °C for 1 min respectively. The FT-IR spectra are shown in Fig. 4. The intense broad band observed at 3442 cm$^{-1}$ and 1627 cm$^{-1}$ are due to the O-H stretching vibrations and bending vibrations of H$_2$O, respectively$^{36}$. The peak at 1039 cm$^{-1}$ corresponds to the O-W-O bonds of WO$_3$. It can be observed that the peak intensity of the 3442 cm$^{-1}$ significantly reduced under UV irradiation for 1 min, while the peak intensity is only weakened slightly after heating at 120 °C for 1 min, indicating that the strategy of UV irradiation has distinct superiority for the remove of the water. FT-IR results of the samples irradiated with UV light for different time were obtained (Fig. S5). There is a distinct decreasing trend of the peak intensity at 3442 cm$^{-1}$ as the time increase, indicating the gradual removal of water.

Based on the results and analysis above, the UV-light irradiation is an effective method to eliminate the water produced during the hydrogen sensing process. Ascribing to that, the stability and sensitivity of the hydrogen sensor under UV irradiation are greatly improved.

**Conclusions**

In summary, Pt/WO$_3$ nanosheets have been successfully fabricated and deposited on an FBG for hydrogen detection. Different from previous reports, an UV-light irradiation strategy was introduced into the hydrogen sensing process to eliminate the produced water based on the water photolysis effect of Pt/WO$_3$. Ascribing to that, the hydrogen sensor under UV irradiation exhibits significantly improved long-term stability through experimental tests over 3 months. The sensor also shows higher sensitivity (0.023 pm/ppm) and resolution (43.5 ppm) with UV irradiation than that without UV irradiation. Through the FT-IR spectra, the UV irradiation on the decomposition of the water produced in the hydrogen sensing process is confirmed. This study provides a new strategy of UV-light irradiation to promote the long-term stability of a hydrogen sensor with Pt/WO$_3$ as the sensing element.

**Methods**

**Synthesis.** WO$_3$ · H$_2$O nanosheets were synthesized by a hydrothermal method as reported in a previous work$^{36}$. In a typical process, 0.66 g of sodium tungstate (Na$_2$WO$_4$ · 2H$_2$O) and 0.4 g of citric acid were mixed and dissolved into 40 mL of distilled water under 10 min of magnetic stirring to form a transparent solution. Then the aqueous solution was slowly acidified to a pH range of 1–1.2 with 10 mL of 3 mol/L HCl. Subsequently, a yellow
precipitate was obtained, and 0.8 g oxalic acid was added into solution. After 20 min of stirring, the solution was transferred into a 50-mL Teflon-lined stainless steel autoclave, that was sealed and heated at 160 °C for 12 h, and then cooled to room temperature naturally. The obtained precipitates were separated by centrifugation, washed several times with distilled water and absolute ethanol and then dried in air at 60 °C for 4 h. After that, 1 mmol of the as-synthesized WO$_3$·H$_2$O and 0.2 mmol acetyl acetone platinum (Pt(acac)$_2$) were mixed. The mixture was ground sufficiently and annealed in air at 315 °C at a heating rate of 10 °C/min for 2 h to obtain Pt/WO$_3$ nanosheets.

**Characterization.** The phase of the Pt/WO$_3$ was investigated by X-ray diffraction (XRD) using a Bruker D8 Advance X-ray diffractometer with Cu K$_\alpha$ X-ray source. The morphology was characterized by using a Zeiss Ultra Plus field emission scanning electron microscope (FE-SEM). Transmission electron microscopic (TEM), high resolution transmission electron microscopic (HRTEM) images and selected area electron diffraction (SAED) pattern were collected using a JEOL JEM-2100F STEM/EDS microscope. FT-IR spectra were obtained with Thermo Scientific Nicolet 6700. The oxidation state and relative chemical composition of Pt/WO$_3$ were evaluated by X-ray photoelectron spectroscopy (XPS) in a Kratos AXIS-ULTRA DLD-600 W.

**Fabrication of sensor probe.** The sensor device was fabricated by uniformly coating the as-synthesized Pt/WO$_3$ powder mixed with an appropriate amount of de-ionized water on the FBG fiber, and the FBG fiber was fixed on a glass substrate with a groove so that the Pt/WO$_3$ coating could be stably immobilized on the section of the FBG grating.

**Hydrogen sensing characterization.** Figure 5 shows a schematic of the configuration of the FBG hydrogen sensing characterization system. The system consists of a tunable light source, a 3-dB optical fiber coupler, a sensing probe and a customized optical spectrum analyzer with a resolution of 1 pm. The sensing probe consists of two FBGs, one employed for temperature compensation, and other FBG coated with Pt/WO$_3$ detect hydrogen as the sensing probe. The hydrogen sensing performance test was conducted at room temperature with nitrogen as the carrier gas (with an ambient 50% RH). Mixture of nitrogen and hydrogen with variable H$_2$ concentrations were provided by a Beijing Sevenstar Electronics CS200 flowmeter with a resolution of 1 ppm. The hydrogen sensing process was divided into two stages: (i) the sensor probe was exposed to a mixture of nitrogen and hydrogen with a variable H$_2$ concentrations and the spectrum of the tested FBG with Pt/WO$_3$ was measured and (ii) after that, the sample was exposed to air along with (or without) ultraviolet light ($\lambda$ = 365 nm) irradiation for 1 min at 8 W/cm$^2$ using an EXFO LX300 smart LED point light curing equipment to decompose the water that was generated in stage (i). The relationship between the center wavelength of the FBG and the temperature change has been reported in our previous work$^{15}$, and the FBG theory based on the Pt/WO$_3$ coatings can be described as:

$$\Delta \lambda = \frac{a \times b \times x^n}{1 + b \times x^n}$$  \hspace{1cm} (7)

where “a” is related to the hydrogen media sensing material and “b” and “n” are constants of reactions. A detail derivation of Equation (7) was presented in the Supplementary Information.
