The Feynman propagator in curved spacetime admits an asymptotic (Schwinger-DeWitt) series expansion in derivatives of the metric. Remarkably, all terms in the series containing the Ricci scalar \( R \) can be summed exactly. We show that this (non-perturbative) property of the Schwinger-DeWitt series has a natural and equivalent counterpart in the adiabatic (Parker-Fulling) series expansion of the scalar modes in an homogeneous cosmological spacetime. The equivalence between both \( R \)-summed adiabatic expansions can be further extended when a background scalar field is also present, as required in the basic models of inflation.

I. INTRODUCTION

One of the most useful tools in the theory of quantized fields in curved spacetime [1–3] and semiclassical gravity [4] is the Schwinger-DeWitt (SDW) adiabatic (proper-time) expansion of the Feynman propagator [5]. It consists in an expansion in number of derivatives of the metric with a fixed leading term. This expansion is of utmost importance in the renormalization of expectation values of the stress-energy tensor. It also plays a fundamental role in the evaluation of the effective action. The SDW expansion identifies the ultraviolet divergences (UV) of Green’s functions in a generic spacetime and it can be accompanied with the point-splitting technique [6, 7] to renormalize expectation values of observables such as the stress-energy tensor. The SDW representation of the Feynman two-point function for a scalar field can be regarded as a special case of the Hadamard expansion, corresponding to a particular choice of the undetermined biscalar coefficient in the Hadamard representation [8]. The SDW expansion can also be rederived from the local momentum-space representation introduced by Bunch and Parker [9]. In this context, Bekenstein and Parker [10] obtained an approximated form for the propagator (the Gaussian approximation) involving, in the coincidence limit, an exponential of the scalar curvature \( R \). Remarkably, it has been shown that this non-perturbative exponential factor \( \exp[-is(\xi - 1/6)R] \) is indeed the sum of all terms containing \( R \) in the adiabatic proper-time series [1, 11, 12]. This result has major physical consequences to account for the effective dynamics of the universe and the observed cosmological acceleration. By integrating out the quantum fluctuations of an ultra-low-mass scalar field the effective gravitational dynamics provides negative pressure to suddenly accelerate the Universe, without the need of an underlaying cosmological constant [13–15] (see also [16]). This approach can also alleviate [17] the increasing \( H_0 \) tension of the standard cosmological model. Other physical applications are reported in [18–20].

Within the cosmological context, and for Friedmann-Lemaître-Robertson-Walker (FLRW) spacetimes, it is convenient to regard the Feynman Green’s function as a sum in modes. The modes themselves admit an adiabatic expansion, also with a fixed leading term, in number of derivatives of the expansion factor \( a(t) \). The modes of a scalar field have a natural WKB-type adiabatic expansion, which can be exploited to compute the renormalized expectation values of the stress-energy tensor, as first proposed and studied by Parker and Fulling (PF) [21] (for an historical account see [22]). This adiabatic method identifies the UV subtracting terms directly in momentum space. One advantage of the PF adiabatic expansion relies on the systematics of the algorithm to determine arbitrary higher-order adiabatic terms. Furthermore, it is also a very efficient method of renormalization in homogeneous cosmological spacetimes [23–25], especially in studies in which numerical computations are finally required. The method has been extended to deal with Dirac fields [30–35] and with scalar [36, 37] and electromagnetic backgrounds [38–43]. In FLRW backgrounds both adiabatic schemes of renormalization (PF and SDW) can be applied and it can be shown to be equivalent [44–46]. See [47] for a discussion on the equivalence among different renormalization schemes.

The aim of this work is to show that the \( R \)-summed form of the adiabatic Schwinger-DeWitt expansion of the propagator has an equivalent counterpart in the adiabatic Parker-Fulling expansion of the field modes. We will also
show that this result is naturally extended when a background scalar field is present, as happens in the single field models of inflation \[48,49\]. As a byproduct of our analysis we will provide a direct derivation of the effective action incorporating the non-perturbative factors associated to the scalar curvature and the scalar field background.

The paper is organized as follows. In Section \(\text{II}\) we briefly introduce the (Schwinger-DeWitt) proper-time expansion of the Feynman propagator and the Parker-Fulling adiabatic expansion of the field modes on a FLRW spacetime. We also describe the equivalence between both adiabatic expansions. In Section \(\text{III}\) we introduce the \(R\)-summed form of the SDW expansion and propose a new \(R\)-summed form of the traditional adiabatic WKB-type expansion of the field modes in a FLRW spacetime. We provide strong evidence for the equivalence between both \((R\)-summed\) expansions. In Section \(\text{IV}\) we generalize the previous result by also including a classical background scalar field with a Yukawa-type coupling to the quantized scalar field. As a simple byproduct of our analysis we also give the effective Lagrangian induced by quantum fluctuations of the quantized scalar field. Finally, in Section \(\text{V}\) we summarize our main conclusions.

\section{II. SCHWINGER-DEWITT AND PARKER-FULLING ADIABATIC EXPANSIONS}

\subsection{A. Schwinger-DeWitt adiabatic expansion}

Let us consider a quantized scalar field \(\phi\) on a general spacetime. The associate Feynman propagator \(G(x,x') = -i \langle 0 | T \phi(x) \phi(x') | 0 \rangle\) satisfies the equation

\[
(\Box_x + m^2 + \xi R)G(x,x') = -|g(x)|^{-1/2} \delta(x - x') ,
\]

where \(\xi\) parametrizes the coupling to the scalar curvature. We follow the convention and notation given in \([1]\). To implement the renormalization program it is very useful to construct an adiabatic expansion of \(G(x,x')\) in terms of the number of derivatives of the background metric. This is the basic idea of the SDW expansion \([5]\). To obtain the desired expansion, one writes the propagator in terms of the proper-time form

\[
G(x,x') = -i \int_0^\infty ds \ e^{-im^2 s}(x,s|x',0)
\]

where \(m^2\) is understood to have an infinitesimal negative imaginary part \(-i\varepsilon\). The kernel \(\langle x,s|x',0 \rangle\) satisfies the Schrödinger-type equation

\[
i \frac{\partial}{\partial s} \langle x,s|x',0 \rangle = (\Box_x + \xi R) \langle x,s|x',0 \rangle ,
\]

with the boundary condition \(\langle x,s|x',0 \rangle \sim |g(x)|^{-1/2} \delta(x - x')\) as \(s \to 0\). Equation (3) implies that, by iteration, \(\langle x,s|x',0 \rangle\) can be further expanded in powers of the proper-time parameter. This can be made explicit by introducing a function \(F(x,x';is)\) defined by the relation

\[
\langle x,s|x',0 \rangle = i \frac{\Delta^{1/2}(x,x')}{(4\pi^2(\sigma s)^2)} e^{\frac{-i\sigma s}{2\pi}} F(x,x';is) ,
\]

where \(\Delta(x,x')\) is the Van Vleck-Morette determinant and \(\sigma(x,x')\) is the proper distance along the geodesic from \(x'\) to \(x\). The asymptotic expansion of the function \(F(x,x';is)\) is

\[
F(x,x';s) \sim a_0(x,x') + a_1(x,x')(is) + a_2(x,x')(is)^2 + \cdots ,
\]

where the first coefficients \(a_n(x,x')\) are given, in the coincidence limit \(x \to x'\), by \([2]\) :

\[
a_0(x) = 1 , \quad a_1(x) = -\bar{\xi} R ,
\]

\[
a_2(x) = \frac{1}{180} R_{\alpha\beta\gamma\delta} R^{\alpha\beta\gamma\delta} - \frac{1}{180} R^{\alpha\beta} R_{\alpha\beta} - \frac{1}{6} \left( \frac{1}{5} - \bar{\xi} \right) \Box R + \frac{1}{2\bar{\xi}^2} R^2 ,
\]

and \(\bar{\xi} \equiv \xi - \frac{1}{6}\). Higher-order coefficients \(a_n\) have been calculated in \([50,53]\). Hence, the SDW expansion, at a given adiabatic order \(2n\), takes the form

\[
(2n)G_{SDW}(x,x') = \frac{\Delta^{1/2}(x,x')}{(4\pi^2)} \int_0^\infty ds \ e^{-im^2 s} e^{\frac{-i\sigma s}{2\pi}} \sum_{j=0}^n a_j(x,x')(is)^j .
\]
We recall here that the coefficient $a_j$ is of adiabatic order $2j$. It is clear that the first two terms in (5) make divergent in the ultraviolet (UV) limit, namely, when $s \rightarrow 0$. Higher order terms do not involve any UV divergences for the two-point function. However, the fourth adiabatic order term, $a_2$, is necessary to tame the logarithmic divergences of the stress-energy tensor and the effective action (see also 1,3). There are two issues to note on this expansion. First, one can extend the series to an arbitrary order, although only the first few terms are analytically manageable. Secondly, any higher order term contains only polynomial terms of the curvature, to such an extent that non-local effects are not present at any given adiabatic order. The later was taken into consideration in [11, 12] by proposing a refined expansion which we will describe in the next section. Nevertheless, we will first briefly review to adiabatic Parker-Fulling expansion and the equivalence between this and the SDW expansion in FLRW spacetimes. This is required in order to extend the Parker-Fulling expansion and overcome the former issue.

**B. Parker-Fulling adiabatic expansion**

Let us assume for simplicity a spatially flat metric of the form $ds^2 = dt^2 - a^2(t)d\vec{x}^2$. The scalar field satisfies the equation

$$\Box + m^2 + \xi R)\phi = 0,$$

where $R = 6(\dot{a}^2/a^2 + \ddot{a}/a)$. The quantized field is expanded in Fourier modes as

$$\phi(x) = \frac{1}{\sqrt{2(2\pi a)}} \int d^3k [A_k f_k(x) + A_k^\dagger f_k^*(x)],$$

where $f_k(x) = e^{ikx}h_k(t)$, and $A_k$ and $A_k^\dagger$ are the usual creation and annihilation operators. Substituting (10) into (9) we find $\ddot{h}_k + [\omega^2 + \sigma]h_k = 0$, where $\sigma = (6\xi - \frac{3}{2})/a + (6\xi - \frac{3}{2})/a^2$, and $\omega = \sqrt{\frac{\xi}{a^3} + m^2}$. The adiabatic expansion for the scalar field modes is based on the usual WKB ansatz [1,3]

$$h_k(t) = \frac{1}{\sqrt{W_k(t)}} e^{-i \int W_k(t')dt'}, \quad W_k(t) = \omega^{(0)} + \omega^{(1)} + \omega^{(2)} + \cdots,$$

where the adiabatic order is based on the number of derivatives of the expansion factor $a(t)$. The function $W_k(t)$ obeys the differential equation

$$W_k'' = \omega^2 + \frac{3}{4} \frac{\dot{W}_k^2}{W_k} - \frac{1}{2} \frac{\ddot{W}_k}{W_k}.$$

If we now fix the leading term as $\omega^{(0)} = \omega$ one can substitute the ansatz into Eq. (12), and solve order by order to obtain recursively the different terms of the expansion:

$$\omega^{(1)} = \omega^{(3)} = 0,$$

$$\omega^{(2)} = \frac{1}{2a^3} \left\{ \sigma \omega^2 + \frac{3}{4} \dot{\omega}^2 - \frac{1}{2} \ddot{\omega} \right\},$$

$$\omega^{(4)} = \frac{1}{2a^3} \left\{ 2\sigma \omega \omega^{(2)} - 5\omega^{(2)} \omega^{(2)} + \frac{3}{2} \dot{\omega} \omega^{(2)} - \frac{1}{2} (\omega \ddot{\omega} + \omega^{(2)} \dot{\omega}) \right\}.$$

Note that, in this expansion, the coefficients of odd adiabatic order, namely $\omega^{(2n+1)}$, are always zero. From the mode expansion we can expand any observable at any fixed adiabatic order. For the two-point function at the coincident limit $G(x,x) \sim \int dkk^2 W_k^{-1}$ we have

$$(2n)_{\text{PP}} G_{\text{PP}}(x,x) = \frac{1}{4 \pi^2 a^3(t)} \int_0^\infty dkk^2 \left\{ \omega^{-1} + (W^{-1})^{(2)} + (W^{-1})^{(4)} + \ldots + (W^{-1})^{(2n)} \right\},$$

where the first terms are

$$(W^{-1})^{(2)} = -\frac{5m^4a^2}{8a^2\omega^5} + \frac{m^2a^2}{2a^2\omega^3} \frac{3\xi \dot{a}^2}{a^2 \omega} + \frac{\dot{a}^2}{2a^2 \omega} + \frac{m^2 a}{4a \omega} - \frac{3\xi \dot{a}}{a \omega} + \frac{\dot{a}}{2a \omega}.$$
Just as the SDW expansion, only the first two terms in (14) are divergent, in such a way that it serves to isolate all the ultraviolet divergences of the propagator. After subtracting the divergences one gets a finite result. This mechanism can also be used to renormalize the expectation values of the stress-energy tensor. The overall procedure is traditionally known as the adiabatic regularization method [1, 21]. Even though we have written (12) in a compact form, we can further expand this expression and obtain an analytic expression for \( \omega^{(2n)} \) in terms of the lower adiabatic orders (see for instance [44]).

C. Comparison between the Schwinger-DeWitt and Parker-Fulling adiabatic expansions

To compare both adiabatic expansions we have to restrict the Schwinger-DeWitt expansion of the Feynman propagator to the (spatially flat) FLRW universe considered above. Moreover, it is natural to compare the expansion given in [11, 12]. It has been proved that for general spacetimes in arbitrary dimensions, this expansion depends on all the ultraviolet divergences of the propagator. After subtracting the divergences one gets a finite result. This mechanism can also be used to renormalize the expectation values of the stress-energy tensor. The overall procedure is traditionally known as the adiabatic regularization method [1, 21]. Even though we have written (12) in a compact form, we can further expand this expression and obtain an analytic expression for \( \omega^{(2n)} \) in terms of the lower adiabatic orders (see for instance [44]).

III. \( R \)-SUMMED FORM OF THE ADIABATIC EXPANSIONS

As stressed in the introduction, a very important result concerning the SDW adiabatic expansion is that the expansion of the kernel \( \langle x, s'|x', 0 \rangle \) of (9) can be rewritten in the form [11, 12]

\[
\langle x, s|x', 0 \rangle = i^{(2n)} G^{(2n)}_{SDW}(x, x') = \frac{1}{4\pi^2a^3} \int_0^\infty dk k^2 \left[ \frac{1}{(k^2 + m^2)^{1/2}} - \frac{\bar{\xi} R(x)}{2(k^2 + m^2)^{3/2}} \right] + R(x) \frac{a_2(x)}{288\pi^2} + \frac{a_3(x)}{16\pi^2m^4} + \frac{a_4(x)}{16\pi^2m^4}.
\]

This provides enough evidence for the equivalence at any adiabatic order

\[
(2n) G_{PF}(x, x) = i^{(2n)} G^{(2n)}_{SDW}(x, x).
\]

In the next section we will show that this equivalence can also be extended to the \( R \)-summed form of the SDW expansion given in [11, 12].

\[
(2n) \tilde{G}_{SDW}(x, x') = \Delta^{1/2}(x, x') \frac{d}{ds} \int_0^\infty \frac{ds}{(2\pi)^2} e^{-is^2 + \bar{\xi} s} \sum_{j=0}^n (is)^2 \hat{a}_j(x, x') .
\]

Expansion (20) indicates that there is a subset of the original series that can be exactly summed and factorized out in the exponential term of (19). As we have already mentioned, this non-perturbative effect was further applied to...
study the observed cosmological acceleration \[13–15\]. The main feature of this expansion is that no \( R \) term appears explicitly in the \( \ddot{a}_n \) coefficients. We will inherit this characteristic for the Parker-Fulling expansion. The natural way of doing this is to include the same \( R \)-summed contribution of \[13\] into the leading term of the adiabatic expansion, namely in \( \omega^{-1} \). We note that the terms

\[
\left[ \frac{1}{(\frac{\dot{a}^2}{a^2} + m^2)^{1/2}} - \frac{\ddot{\xi} R}{2(\frac{\dot{a}^2}{a^2} + m^2)^{3/2}} \right]
\]

(24)

in the momentum integral in \[17\] can be regarded as the leading terms in the expansion of

\[
\frac{1}{(\frac{\dot{a}^2}{a^2} + m^2 + \ddot{\xi} R)^{1/2}} = \frac{1}{(\frac{\dot{a}^2}{a^2} + m^2)^{1/2}} - \frac{\ddot{\xi} R}{2(\frac{\dot{a}^2}{a^2} + m^2)^{3/2}} + O(R^2).
\]

(25)

This simple observation suggests the following ansatz for the first term in the new adiabatic expansion

\[
\bar{\omega}^{(0)} \equiv \bar{\omega} = \sqrt{\frac{k^2}{a^2(t)} + m^2 + \ddot{\xi} R}.
\]

(26)

Therefore, the proposed alternative form of the adiabatic expansion reads (we shall assume \( M^2(t) \equiv m^2 + \ddot{\xi} R > 0 \))

\[
h_k(t) = \frac{1}{\sqrt{W(t)}} e^{-i \int W'(t')dt'}, \quad \bar{W}_k(t) = \bar{\omega}^{(0)} + \bar{\omega}^{(1)} + \bar{\omega}^{(2)} + \cdots,
\]

(27)

where the function \( \bar{W}_k(t) \) obeys the differential equation

\[
\bar{W}_k^2 = \bar{\omega}^2 + \dot{\bar{\omega}} + \frac{3}{4} \bar{W}_k^2 \frac{1}{\bar{W}_k} \ddot{\bar{W}}_k,
\]

(28)

with \( \bar{\sigma} \equiv \sigma - (\xi - 1/6) R \). Having fixed the leading term the higher-order adiabatic terms are univocally determined. Furthermore, we can make use of expressions \[13\], upgrading \( \sigma \rightarrow \bar{\sigma} \equiv \sigma - \ddot{\xi} R \) and \( \omega \rightarrow \bar{\omega} \). It is important to point out that the choice of the leading term \[20\] does not imply that we consider the function \( R \) of adiabatic order zero. This function is still considered of adiabatic order two. Hence, if we use \[13\] to get the adiabatic terms, we must truncate the expressions to fix properly their adiabatic order. The corresponding expansion for the two-point function up to the \( 2n \)-th adiabatic order is

\[
^{(2n)}\tilde{G}_{PF}(x, x) = \frac{1}{4\pi^2a^3(t)} \int_0^\infty dkk^2 \left\{ \bar{\omega}^{-1} + (\bar{W}^{-1})^{(2)} + \cdots + (\bar{W}^{-1})^{(2n)} \right\},
\]

(29)

where now,

\[
(\bar{W}^{-1})^{(2)} = -\frac{5k^4a^2}{8a^6\omega^5} + \frac{3k^2a^2}{4a^4\omega^3} - \frac{k^2\bar{a}}{4a^2\omega^3} - \frac{\dot{\bar{a}}^2}{8a^2\omega^3} + \frac{\dot{a}}{4a\omega^3}.
\]

(30)

We can systematically perform higher order calculations assisted, for instance, with the Mathematica software. There is an algorithmic solution to generate recursively all higher order terms in the adiabatic expansion. In Appendix \[13\] we give more details of this expansion.

### A. Equivalence of the \( R \)-summed form of the adiabatic expansions

Our conjecture is that \[29\] generates the same expansion as the propagator obtained from the kernel \[20\] when we restrict to a FLRW spacetime and in the coincident limit, i.e.

\[
^{(2n)}G_{PF}(x, x) = i^{(2n)}\tilde{G}_{SDW}(x, x).
\]

(31)

In order to test this we use the above mentioned result \[18\] from \[14\] and check whether

\[
^{(2n)}G_{PF}(x, x) - i^{(2n)}G_{PF}(x, x) = i \left( ^{(2n)}\tilde{G}_{SDW}(x, x) - i^{(2n)}G_{SDW}(x, x) \right)
\]

(32)
holds for a given adiabatic order. Note that (32) is equivalent to (31), but since both sides of (32) involve only finite quantities we can check more directly the proposal.

The right-hand-side of (32) can be written as a finite integral in the proper-time parameter (recall that $m^2 \equiv m^2 - i\epsilon$ and this avoids any divergence as $s \rightarrow \infty$)

$$\langle 2 \rangle G_{SDW}(x, x) - \langle 2 \rangle G_{SDW}(x, x) = \frac{1}{4\pi}\int_0^\infty ds\int_0^\infty ds' \sum_{j=0}^n \left[ e^{-is(m^2 + i\xi R)a_j(x)(s)} - e^{-ism^2a_j(x)(s)} \right].$$

(33)

On the other hand, the left-hand-side of (32) can be written as the following integral

$$\langle 2 \rangle G_{PF}(x, x) - \langle 2 \rangle G_{PF}(x, x) = \frac{1}{4\pi^2a^3(t)}\int_0^\infty dk^2\sum_{j=0}^n \left[ (\bar{W}^{-1})^{(j)} - (W^{-1})^{(j)} \right].$$

(34)

These two integrals are finite by construction, and can be evaluated analytically. First, we will give explicitly the outcome of the integrals above for $n = 1, 2$ and then we will extend the result for an arbitrary $n$.

1. Cases $n = 1, 2$

On one hand, the result of the SDW integral (33) for $n = 1$ is

$$\langle 2 \rangle G_{SDW}(x, x) - \langle 2 \rangle G_{SDW}(x, x) = -\frac{i}{2\pi^2}\left[ M^2 \log \left( \frac{M^2}{m^2} \right) - \bar{\xi}R \right],$$

(35)

where $M^2 = m^2 + \bar{\xi}R$, and for $n = 2$ we find

$$\langle 4 \rangle G_{SDW}(x, x) - \langle 4 \rangle G_{SDW}(x, x) = -\frac{i}{2\pi^2}\left[ M^2 \log \left( \frac{M^2}{m^2} \right) - \bar{\xi}R + \left( \bar{a}_2 - \frac{a_2}{M^2} \right) \right].$$

(36)

On the other hand, one can directly compute the PF integral given in eq. (34) using the adiabatic expansions given in sections II B and III. For $n = 1$ we find

$$\langle 2 \rangle G_{PF}(x, x) - \langle 2 \rangle G_{PF}(x, x) = \frac{1}{4\pi^2}\left[ M^2 \log \left( \frac{M^2}{m^2} \right) - \bar{\xi}R \right],$$

(37)

and for $n = 2$

$$\langle 4 \rangle G_{PF}(x, x) - \langle 4 \rangle G_{PF}(x, x) = \frac{1}{4\pi^2}\left[ M^2 \log \left( \frac{M^2}{m^2} \right) - \bar{\xi}R + \left( \bar{a}_2 - \frac{a_2}{M^2} \right) \right].$$

(38)

Comparing (36) with (38), it is clear that for the lowest adiabatic orders, relation (32) is satisfied.

2. General case

Now, let us generalize the preceding result for an arbitrary $n$. For $n \geq 2$, expression (33) can be also directly integrated, and the general result is

$$i\langle 2n \rangle G_{SDW}(x, x) - \langle 2n \rangle G_{SDW}(x, x) = \frac{1}{4\pi^2}\left[ M^2 \log \left( \frac{M^2}{m^2} \right) - \bar{\xi}R + \sum_{j=2}^n (j - 2)! \left( \bar{a}_j - \frac{a_j}{M^{2j-2}} \right) \right].$$

(39)

To evaluate (41) for $n \geq 2$ one has to compute explicitly the PF adiabatic expansion up to and including the adiabatic order $2n$ and perform the mode integral. Based on all previous results, the conjectured result of $\langle 2n \rangle G_{PF}(x, x) - \langle 2n \rangle G_{PF}(x, x) \geq 2$ is given by

$$\langle 2n \rangle G_{PF}(x, x) - \langle 2n \rangle G_{PF}(x, x) = i\langle 2n \rangle G_{SDW}(x, x) - \langle 2n \rangle G_{SDW}(x, x) =$$

$$\frac{1}{4\pi^2}\left[ M^2 \log \left( \frac{M^2}{m^2} \right) - \bar{\xi}R + \sum_{j=2}^n (j - 2)! \left( \bar{a}_j - \frac{a_j}{M^{2j-2}} \right) \right].$$

(40)
We have tested this conjecture up to and including the eight adiabatic order. Since the computations are rather involved we refer the reader to Appendix C where we give explicit expressions for \( \bar{a}_3 \) and \( \bar{a}_4 \). We think this provides enough evidence for the general validity of the conjecture. Furthermore, we can give analytic results for the following finite integrals in both approaches \((n > 1)\)

\[
\frac{1}{4\pi^2a^3(t)} \int_0^\infty dkk^2(W^{-1})^{2n} = \frac{(n - 2)!}{(4\pi)^2} \frac{\bar{a}_n}{M^{2n-2}} = \frac{i}{(4\pi)^2} \int_0^\infty \frac{ds}{(is)^2} e^{-is(m^2 + \xi R)} \bar{a}_n(x)(is)^n. \tag{41}
\]

IV. GENERALIZATION: including a scalar background field

We can also extend the above discussion to include an external scalar field \( \Phi \) with a Yukawa-type coupling. The action of our quantized scalar field \( \phi \) is now

\[
S_m = \int d^4x \sqrt{-g} \frac{1}{2} (g^{\mu\nu} \nabla_\mu \phi \nabla_\nu \phi - m^2 \phi^2 - \xi R \phi^2 - h \Phi \phi^2),
\]

where \( h \) is the coupling constant between both scalar fields. The equation of motion reads

\[
(\Box + m^2 + h \Phi + \xi R) \phi = 0,
\]

and the expansion for the heat-kernel turns out to be

\[
\langle x, s | x', 0 \rangle = i \frac{\Delta^{1/2}(x, x')}{(4\pi)^2(is)^2} e^{\frac{c(x, x')}{2is}} (E_0(x, x') + E_1(x, x')(is) + E_2(x, x')(is)^2 + \cdots). \tag{44}
\]

In the coincidence limit \( x \to x' \) the coefficients \( E_n \) are

\[
E_0(x) = 1
\]

\[
E_1(x) = -(\xi R + h \Phi)
\]

\[
E_2(x) = \frac{1}{180} R_{\alpha\beta\gamma\delta} R^{\alpha\beta\gamma\delta} - \frac{1}{180} R^{\alpha\beta} R_{\alpha\beta} - \frac{1}{6} \left( \frac{1}{5} - \xi \right) \Box R + \frac{1}{2} (\xi R + h \Phi)^2 + \frac{1}{6} h \Box \Phi. \tag{45}
\]

The expression for \( E_3(x) \) has 46 terms and it is given, for instance, in [51]. Note that \( \Phi \) should be considered here as a variable of adiabatic order 2. The expression of the second coefficient \( E_1 \) of (45) suggests that we can factorize in the same way as before the entire term \( \xi R + h \Phi \), also in the form of an exponential. Hence, we can also write

\[
\tilde{G}_{SDW}(x, x) = \frac{1}{(4\pi)^2} \int_0^\infty \frac{ds}{(is)^2} e^{-is(m^2 + \xi R + h \Phi)s} \sum_j (is)^j \tilde{E}_j(x). \tag{46}
\]

The lower coefficients in the new expansion are \( \tilde{E}_0(x) = 1, \tilde{E}_1(x) = 0 \) and

\[
\tilde{E}_2(x) = \frac{1}{180} R_{\alpha\beta\gamma\delta} R^{\alpha\beta\gamma\delta} - \frac{1}{180} R^{\alpha\beta} R_{\alpha\beta} - \frac{1}{6} \left( \frac{1}{5} - \xi \right) \Box R + \frac{1}{6} h \Box \Phi. \tag{47}
\]

Note that \( \tilde{E}_n \) contain no terms which vanish when \( R \) and \( \Phi \) (but not their covariant derivatives) are replaced by zero. Therefore, all the dependence on \( R \) and \( \Phi \) is codified in the exponential in (46). In a similar way, we can redo the Parker-Fulling type adiabatic expansion (27) with a new choice for the leading term

\[
\tilde{\omega}^{(0)} = \sqrt{\frac{k^2}{a^2(t)}} + m^2 + \xi R + h \Phi. \tag{48}
\]

Hence, the results obtained in Section III regarding the equivalence between both (Schwinger-DeWitt and Parker-Fulling) adiabatic expansions, are now

\[
(2n)^{\tilde{G}_{PF}(x, x)} - (2n)^{\tilde{G}_{SDW}(x, x)} = \frac{1}{(4\pi)^2} \frac{M^2 \log \left( \frac{M^2}{m^2} \right) - \xi R - h \Phi + \sum_{j=2}^n (j - 2)! \left( \frac{\tilde{E}_j}{M^{2j-2}} - \tilde{E}_j \frac{M^2}{m^{2j-2}} \right)}{M^{2j-2}}
\]

\[
= i \left( (2n)^{\tilde{G}_{SDW}(x, x)} - (2n)^{\tilde{G}_{SDW}(x, x)} \right), \tag{49}
\]

where \( M^2 \) has been redefined as \( M^2 = m^2 + \xi R + h \Phi \).
A. Effective Action

We briefly show a direct application of the above result. The formal quantum effective action $W$, obtained by integrating out the degrees of freedom of the quantized scalar field, is given by \[ W = S_{\text{class}} - \frac{1}{2} \int d^4x \int_0^\infty \frac{ds}{is} e^{-ism^2} \langle x, s | x, 0 \rangle , \] (50)

where $S_{\text{class}}$ is the classical action including the gravitational contribution. The quantum corrected part can be further written as

$$
\frac{1}{32\pi^2} \int d^4x \int_0^\infty \frac{ds}{s^3} e^{-ism^2} F(x,x;is) .
$$

(51)

The expression above is UV divergent and it requires renormalization subtractions up to and including the fourth adiabatic order. Following the same approach as for the Feynman propagator we will use the extended $R$-summed expansion until second adiabatic order to approximate $F(x,x;is)$ and the usual SDW expansion until second order for the subtraction terms. This ensures that the final quantity is finite. We have then,

$$
W = S_{\text{class}} + \frac{1}{32\pi^2} \int d^4x \int_0^\infty \frac{ds}{s^3} e^{-ism^2} [e^{-is(\xi R + h\Phi)} (1 + \bar{E}_1(x)(is) + \bar{E}_2(x)(is)^2) - (1 + E_1(x)(is) + E_2(x)(is)^2)] .
$$

(52)

With this input, and after performing the finite integration in proper-time $ds$, one gets

$$
W = S_{\text{class}} + \int d^4x \ L_{\text{eff}}
$$

(53)

where

$$
L_{\text{eff}} = \frac{1}{64\pi^2} \left\{ (\xi R - h\Phi) \left( m^2 + \frac{3}{2} (\xi R - h\Phi) \right) - (M^4 + \bar{E}_2(x)) \log \left( \frac{M^2}{m^2} \right) \right\}
$$

$$
+ \frac{i}{64\pi} \left[ M^4 + 2\bar{E}_2 \right] \Theta (-M^2) .
$$

(54)

The imaginary part of the effective action accounts for the particle creation phenomena induced by the given metric and also by the scalar field background. Note that, for $h = 0$ (no coupling to the scalar background field), we recover the effective action calculated in \cite{13} by means of the $\zeta$-function regularization. Here we have derived the effective action in a very straightforward way.

V. CONCLUSIONS AND FINAL COMMENTS

The SDW adiabatic expansion of the Feynman propagator is a basic tool in quantum field theory in curved spacetime. A parallel WKB-type adiabatic expansion for the field modes in a FLRW spacetime was given by Parker and Fulling in \cite{21}. Both expansions have been used to implement the renormalization program in curved spacetime and, in particular, in FLRW universes.

The non-perturbative factor $\exp(-is(\xi - \frac{1}{6})R)$ in the heat-kernel of SDW expansion, first discovered in \cite{11,12}, is of major importance in unraveling physical consequences in cosmology \cite{13,17}. In this expansion, the focus is not in the renormalization subtractions, which are already well-defined in the standard adiabatic expansion. Here, the point is that the non-perturbative factor partially captures non-perturbative effects of the adiabatic vacuum. Within this viewpoint, one could expect that a similar $R$-summed form of the Parker-Fulling adiabatic expansion for the field modes can also be constructed. We have provided here such a construction. We have also tested the equivalence between both, Schwinger-DeWitt and Parker-Fulling $R$-summed expansions in FLRW universes, until and including the adiabatic order eight. We think this provides strong evidence of the equivalence to an arbitrary adiabatic order, as provided by the general formula \cite{40}. This can be useful to improve the computations of physical observables, such as the stress-energy tensor, in the adiabatic approach.

Furthermore, we have added a Yukawa-type interaction between the quantized scalar field and a classical background scalar field $\Phi$, extending the $R$-summed solution to also include a $\Phi$-summed contribution. This is specially relevant in cosmological scenarios where the classical inflation is coupled to the quantized matter field, as in the preheating epochs. We believe it could also be interesting to explore additional non-perturbative factorizations for quantized matter field in presence of gauge field backgrounds.

Appendix A: Relation between \( a_n \) and \( \bar{a}_n \)

The relation between the functions \( \bar{F}(x, x; is) \) and \( F(x, x; is) \) is given by

\[
\bar{F}(x, x; is) \exp(-is\xi R) = F(x, x; is),
\]

where the functions \( \bar{F}(x, x; is) \) and \( F(x, x; is) \) can be expanded in powers of \( s \) as

\[
\bar{F}(x, x; is) = \bar{a}_0(x) + \bar{a}_1(x)(is) + \bar{a}_2(x)(is)^2 + \ldots \\
F(x, x; is) = a_0(x) + a_1(x)(is) + a_2(x)(is)^2 + \ldots
\]

Expanding the exponential in powers of the scalar curvature and combining the terms with equal powers of \( s \) we arrive to the following relation between \( a_n \) and \( \bar{a}_n \)

\[
\bar{a}_n = \sum_{k=0}^{n} a_{n-k} \frac{(\xi R)^k}{k!}
\]

In particular, for the first terms, we have

\[
\bar{a}_0 = a_0 = 1, \\
\bar{a}_1 = a_1 + \xi R = 0, \\
\bar{a}_2 = a_2 - \frac{1}{2}(\xi R)^2, \\
\bar{a}_3 = a_3 + a_2\xi R - \frac{1}{3}(\xi R)^3,
\]

where we have used \( a_0 = 1 \) and \( a_1 = -\xi R \). If we add an external background field, relation (A4) also holds for the coefficients \( E_n \) by doing the change \( \xi R \rightarrow \xi R + h\Phi \).

Appendix B: \( R \)-summed Parker-Fulling adiabatic expansion

In this section we will briefly explain some details on the \( R \)-summed Parker-Fulling adiabatic expansion introduced in Section III. Starting from the mode equation for the scalar field \( \ddot{h}_k(t) + (\omega^2 + \sigma)h_k(t) = 0 \), and proposing the usual WKB ansatz

\[
h_k(t) = \frac{1}{\sqrt{W(t)}} e^{-\int f(W(t)) dt'}, \quad \tilde{W}_k(t) = \tilde{\omega}^{(0)}(t) + \tilde{\omega}^{(1)} + \tilde{\omega}^{(2)} + \cdots,
\]

we arrive to the following equation for \( \tilde{W}_k(t) \):

\[
\tilde{W}_k^2 = \omega^2 + \sigma + \frac{3}{4} \frac{\dot{W}_k^2}{W_k^2} - \frac{1}{2} \frac{\ddot{W}_k}{W_k}.
\]

If we fix the leading term of the expansion as

\[
\tilde{\omega}^{(0)} \equiv \bar{\omega} = \sqrt{\omega^2 + \xi R} = \sqrt{\frac{k^2}{a^2} + m^2 + \xi R},
\]

we get

\[
\tilde{\omega}^{(1)} = \frac{1}{4} \frac{\dot{W}_k^2}{W_k^2} + \frac{1}{2} \frac{\ddot{W}_k}{W_k}.
\]
the equation \( [B2] \) can be re-written as
\[
\mathcal{W}_k^2 = \dot{\omega}^2 + \sigma + \frac{3}{4} \mathcal{W}_k^2 - \frac{1}{2} \frac{\dot{\mathcal{W}}_k}{\mathcal{W}_k},
\]
(B4)
where \( \sigma = \dot{\xi} - \dot{\xi}_R \), and we can obtain the terms of the adiabatic expansion \([B1]\) as usual: expanding the function \( \mathcal{W}_k \) adiabatically and and regrouping all terms with the same adiabatic order.

Note that, the choice of the leading term as in \([B3]\), does not imply that we consider the function \( R \) of adiabatic order zero. This function is still considered of adiabatic order two. It means that the time derivative of the leading order
\[
\mathcal{\hat{\omega}} = -\frac{2k^2 \hat{a}}{2a^3 \omega} + \frac{\dot{\xi} R}{2\omega},
\]
(B5)
will contain terms of adiabatic order one (\( \sim \dot{a} \)), but also of adiabatic order three (\( \sim \dot{R} \)). As a consequence of this result, if we use the expressions given in \([B3]\) to compute the next-to-leading-order terms of the adiabatic expansion, we have to truncate them to get only the terms with the correct adiabatic order. For example, for \( \mathcal{\hat{\omega}}^{(2)} \) we get
\[
\mathcal{\hat{\omega}}^{(2)} = \frac{\dot{\sigma}}{2 \omega} + \frac{3 \dot{\omega}^2}{8 \omega^3} - \frac{\ddot{\omega}}{2 \omega} \biggr|_{(2)} = \frac{\dot{\sigma}}{2 \omega} + \frac{5a^2k^4}{8a^6\omega^5} - \frac{3a^2k^2}{4a^2\omega^3} + \frac{k^2a}{4a^3\omega^3},
\]
(B6)
Similarly, for \( \mathcal{\hat{\omega}}^{(4)} \) and \( \mathcal{\hat{\omega}}^{(6)} \) we obtain
\[
\mathcal{\hat{\omega}}^{(4)} = -\frac{1105a^4k^8}{128a^2\omega_1} + \frac{663a^6k^6}{32a^2\omega_9} - \frac{221a^2k^8a}{32a^2\omega_9} + \frac{507a^4k^4}{32a^2\omega_9} + \frac{183a^2k^4a}{16a^2\omega_7} - \frac{25a^2k^4}{16a^2\omega_7} - \frac{19k^4a^2}{32a^2\omega_7}
\]
\[
+ \frac{15a^2k^2}{4a^2\omega_5} - \frac{9a^2k^2a}{2a^2\omega_5} + \frac{9a^2k^2a}{2a^2\omega_5} - \frac{5a^2k^2}{32a^2\omega_5} - \frac{5a^2k^2}{5a^2\omega_5}
\]
\[
- \frac{7a^2a(3)k^4}{8a^2\omega_5} + \frac{3a^2a(3)k^4}{4a^2\omega_5} - \frac{a(4)k^2}{16a^2\omega_5} - \frac{a(4)k^2}{8a^2\omega_3} - \frac{a(4)k^2}{8a^2\omega_3},
\]
(B7)
where \( g(t) = \dot{\xi} R \), and
\[
\mathcal{\hat{\omega}}^{(6)} = \frac{441a^2k^4}{1024a^4\omega_1} + \frac{745a^4k^6}{512a^4\omega_1} + \frac{24875a^4k^8}{128a^4\omega_1} + \frac{513087a^6k^8}{4a^4\omega_9} + \frac{12155a^4k^4}{128a^4\omega_1} + \frac{34503a^2k^2}{256a^2\omega_9}
\]
\[
+ \frac{179469a^6k^6}{128a^4\omega_9} + \frac{2055a^4k^4}{128a^4\omega_1} + \frac{166059a^6k^6}{128a^4\omega_11} + \frac{5967a^4k^4}{128a^4\omega_11} + \frac{631a^2k^2}{128a^4\omega_11} + \frac{9513a^2k^2}{128a^4\omega_11}
\]
\[
+ \frac{184215a^6k^6}{128a^4\omega_11} + \frac{1989a^4k^4}{128a^4\omega_11} + \frac{1105a^4k^4}{128a^4\omega_11} + \frac{64a^2k^2}{128a^4\omega_11} + \frac{64a^2k^2}{128a^4\omega_11} + \frac{64a^2k^2}{128a^4\omega_11}
\]
\[
+ \frac{133a^2k^4}{64a^2\omega_9} + \frac{128a^4\omega_9}{128a^4\omega_9} + \frac{128a^4\omega_9}{128a^4\omega_9} + \frac{128a^4\omega_9}{128a^4\omega_9} + \frac{128a^4\omega_9}{128a^4\omega_9} + \frac{128a^4\omega_9}{128a^4\omega_9}
\]
\[
+ \frac{221a^2k^4}{64a^2\omega_9} + \frac{663^a\omega_9}{32a^2\omega_9} + \frac{221a^2k^4}{32a^2\omega_9} + \frac{221a^2k^4}{32a^2\omega_9} + \frac{189a(3)^2k^4}{2a^2\omega_9} + \frac{49a(3)^2k^4}{2a^2\omega_9}
\]
\[
- \frac{2091a(3)^2k^4}{128a^2\omega_9} + \frac{285a(4)^2k^4}{128a^2\omega_9} + \frac{55a(4)^2k^4}{128a^2\omega_9} + \frac{27a(5)^2k^4}{128a^2\omega_9} + \frac{315a(5)^2k^4}{128a^2\omega_9} + \frac{75a(5)^2k^4}{128a^2\omega_9}
\]
\[
- \frac{45a^2k^2}{16a^2\omega_7} - \frac{45a^2k^2}{16a^2\omega_7} - \frac{675a^2k^2}{16a^2\omega_7} - \frac{45a^2k^2}{16a^2\omega_7} - \frac{15(3)^2k^2}{16a^2\omega_7} + \frac{675a^2k^2}{16a^2\omega_7} + \frac{45a^2k^2}{16a^2\omega_7}
\]
\[
+ \frac{15a^2k^2}{4a^2\omega_7} + \frac{21a^2k^2}{4a^2\omega_7} + \frac{25a^2k^2}{4a^2\omega_7} - \frac{63a^2k^2}{4a^2\omega_7} - \frac{57a^2k^2}{4a^2\omega_7} + \frac{19a^2k^2}{4a^2\omega_7} + \frac{21a^2k^2}{4a^2\omega_7} + \frac{25a^2k^2}{4a^2\omega_7}
\]
\[
- \frac{63a^2k^2}{32a^2\omega_7} - \frac{57a^2k^2}{32a^2\omega_7} - \frac{19a^2k^2}{32a^2\omega_7} - \frac{75a(3)^2k^4}{32a^2\omega_7} - \frac{15a(3)^2k^4}{32a^2\omega_7} + \frac{45a(3)^2k^4}{32a^2\omega_7} + \frac{7a(3)^2k^4}{32a^2\omega_7}
\]
\[
+ \frac{7a(3)^2k^4}{32a^2\omega_7} + \frac{7a(3)^2k^4}{32a^2\omega_7} - \frac{4a^2\omega_7}{32a^2\omega_7} - \frac{8a^2\omega_7}{32a^2\omega_7} + \frac{4a^2\omega_7}{32a^2\omega_7} + \frac{16a^2\omega_7}{32a^2\omega_7}
\]
\[
+ \frac{16a^2\omega_7}{32a^2\omega_7} + \frac{16a^2\omega_7}{32a^2\omega_7},
\]
and the first terms of the expansion are

\[ \bar{\mathcal{W}}_k^{-1} = \ddot{\omega}^{-1} + (\bar{\mathcal{W}}^{-1})^{(2)} + (\bar{\mathcal{W}}^{-1})^{(4)} \ldots \]  
\hspace{1cm} \text{(B9)}

and the first terms of the expansion are

\[ (\bar{\mathcal{W}}^{-1})^{(2)} = -\frac{\ddot{\omega}}{\omega^2}, \quad (\bar{\mathcal{W}}^{-1})^{(4)} = -\frac{\ddot{\omega}^2}{\omega^4} + \frac{(\ddot{\omega})^2}{\omega^6}. \]  
\hspace{1cm} \text{(B10)}

The results above are also valid when we add an scalar field background \( b \Phi \) by upgrading \( \dot{\omega} \to \sqrt{\dot{\omega}^2 + \dot{\xi} R + h \Phi} \) and \( g(t) \to \dot{\xi} R + h \Phi \).

**Appendix C: \( \bar{a}_3 \) and \( \bar{a}_4 \) coefficients**

In this appendix we give the \( R \)-summed coefficients of adiabatic orders 6 and 8, namely \( \bar{a}_3 \) and \( \bar{a}_4 \) for a FLRW metric:

\[ \bar{a}_3 = \frac{12a^6 \bar{\xi}^2}{a^6} + \frac{4a^6 \xi}{a^6} - \frac{a^{(6)} \xi}{10a} + \frac{3a^6}{3a} + \frac{3a^{(6)}}{140a} + \frac{12a^5 \bar{\xi}^2 \ddot{a}}{a^5} - \frac{21a^4 \xi \ddot{a}}{10a^5} - \frac{11a^4 \dddot{a}}{420a^5} - \frac{3a^2 \xi^2 \dddot{a}^2}{a^4} + \frac{47a^2 \bar{\xi}^2 a^2}{10a^4} + \frac{109a^2 \xi^2 \ddot{a}}{105a^4} - \frac{6a^{(3)} \bar{\xi}^2 a}{a^3} + \frac{67a^{(3)} \xi \ddot{a} a}{10a^3} + \frac{7a \xi^3}{5a^3} - \frac{67a^{(3)} \ddot{a} a}{60a^3} - \frac{5a^3}{18a^3} - \frac{2a^{(5)} \xi a}{5a^2} + \frac{3a^{(5)} a}{35a^2} + \frac{12a^{(3)} \xi^2 a^2}{10a^4} + \frac{59a^{(3)} \xi^2 \ddot{a}}{10a^4} + \frac{9a^{(4)} \xi \ddot{a}}{140a^4} + \frac{97a^{(3)} \ddot{a} a^3}{140a^4} - \frac{11a^{(4)} \dddot{a}}{60a^4} - \frac{2a^{(4)} \xi a}{2a^2} + \frac{41a^{(4)} a}{420a^2} - \frac{3 a^{(3)} \xi^2}{a^2} + \frac{7 (a^{(3)})^2 \xi}{10a^2} - \frac{(a^{(3)})^2}{42a^2}. \]  
\hspace{1cm} \text{(C1)}

\[ \bar{a}_4 = \frac{96a^6 \bar{\xi}^2}{5a^8} - \frac{32a^6 \bar{\xi}}{5a^8} + \frac{8a^8}{15a^8} - \frac{432a^6 \bar{\xi} a^6}{140a^7} + \frac{3807a^6 \bar{\xi} a a^6}{140a^7} - \frac{291a^6 \bar{\xi} a a^6}{140a^7} - \frac{108a^2 a^{(3)} a^5}{5a^6} - \frac{783a^5 a^{(3)} a^5}{140a^6} + \frac{39a^{(3)} a^5}{140a^6} + \frac{20a^6}{10a^6} + \frac{493a^2 a^4}{840a^6} - \frac{937a^2 a^4}{20a^6} + \frac{19a^{(4)} a^4}{420a^3} - \frac{79a^{(4)} a^4}{5a^3} + \frac{63a^6 a^{(3)} a^3}{35a^5} - \frac{209a^{(3)} a^{(3)} a^3}{425a^5} + \frac{12a^2 a^{(5)} a^3}{5a^4} + \frac{17a^{(5)} a^3}{5a^4} - \frac{31a^{(5)} a^3}{5a^4} + \frac{138a^2 a^{(4)} a^3}{35a^5} - \frac{13a^3 a^2}{5a^5} + \frac{53a^3 a^2}{45a^5} - \frac{15a^2 (a^{(3)})^2 a^2}{2a^4} + \frac{361a (a^{(3)})^2 a^2}{70a^4} - \frac{259a (a^{(3)})^2 a^2}{280a^4} - \frac{9a^2 a^{(4)} a^2}{a^4} + \frac{42a^2 a^{(4)} a^2}{70a^4} - \frac{9a^2 a^{(3)} a^3}{70a^3} - \frac{9a^2 a^{(3)} a^3}{140a^3} - \frac{10a^4}{35a^3} + \frac{6a^2 a^{(5)} a}{35a^3} + \frac{29a^{(5)} a}{140a^3} + \frac{43a^{(5)} a}{140a^3} + \frac{39a^{(4)} a^2}{28a^2} - \frac{12a^2 a^{(4)} a^2}{28a^2} + \frac{9a^2 a^{(3)} a^3}{10a^3} + \frac{10a^4}{28a^3} - \frac{5a^5}{35a^3} + \frac{18a (a^{(3)})^2}{35a^2} + \frac{18a (a^{(3)})^2}{35a^2} + \frac{18a (a^{(3)})^2}{35a^2} + \frac{2a^{(6)} a}{35a^2} + \frac{2a^{(6)} a}{35a^2} + \frac{2a^{(6)} a}{35a^2} + \frac{2a^{(6)} a}{35a^2} - \frac{a^{(6)} a}{35a^2} - \frac{a^{(6)} a}{35a^2} - \frac{a^{(6)} a}{35a^2} - \frac{a^{(6)} a}{35a^2}. \]
