Abstract. A $k$-block in a graph $G$ is a maximal set of at least $k$ vertices no two of which can be separated in $G$ by removing less than $k$ vertices. It is separable if there exists a tree-decomposition of adhesion less than $k$ of $G$ in which this $k$-block appears as a part.

Carmesin, Diestel, Hamann, Hundertmark and Stein proved that every finite graph has a canonical tree-decomposition of adhesion less than $k$ that distinguishes all its $k$-blocks and tangles of order $k$. We construct such tree-decompositions with the additional property that every separable $k$-block is equal to the unique part in which it is contained. This proves a conjecture of Diestel.

1. Introduction

Tangles in a graph $G$ are orientations of the low order separations that consistently point towards some ‘highly connected piece’ of $G$. As a fundamental tool for their graph minors project, Robertson and Seymour [8] proved that every finite graph has a tree-decomposition that distinguishes every two maximal tangles.

More recently, $k$-profiles were introduced as a common generalisation of $k$-tangles and $k$-blocks [7]. Here, a $k$-block in a graph $G$ is a maximal set of at least $k$ vertices no two of which can be separated in $G$ by removing less than $k$ vertices. Carmesin, Diestel, Hamann and Hundertmark showed that every graph has a canonical tree-decomposition of adhesion less than $k$ that distinguishes all its $k$-profiles [2].

In [3], these authors asked how one could improve the above tree-decompositions further so that they also display the structure of the $k$-blocks: it would be nice if we could compress any part containing a $k$-block so that it does not contain any ‘junk’.

In this paper, we prove that this is possible simultaneously for all $k$-blocks that can be isolated at all in a tree-decomposition, canonical or not. More precisely, we call a $k$-block separable if it appears as a part in some tree-decomposition of adhesion less than $k$ of $G$. We prove the following, which was conjectured by Diestel [5] (see also [3]).

**Theorem 1.** Every finite graph $G$ has a canonical tree-decomposition $\mathcal{T}$ of adhesion less than $k$ that distinguishes efficiently every two distinct $k$-profiles, and which has the further property that every separable $k$-block is equal to the unique part of $\mathcal{T}$ in which it is contained.
We also prove the following related result:

**Theorem 2.** Every finite graph $G$ has a canonical tree-decomposition $T$ that distinguishes efficiently every two distinct maximal robust profiles, and which has the further property that every separable block inducing a maximal robust profile is equal to the unique part of $T$ in which it is contained.

See Section 2 for a definition of robust and [4] for an example showing that Theorem 2 fails if we leave out ‘robust’. Theorem 2 without its description of the separable blocks is a result of Hundertmark and Lemanczyk [7], which implies the aforementioned theorem of Robertson and Seymour. In Section 4, we give an example showing that it is impossible to ensure that non-maximal robust separable blocks are also displayed by a tree-decomposition which distinguishes all the maximal robust profiles efficiently.

After recalling some preliminaries in Section 2, we develop the necessary tools in Section 3. Then we prove our main result in Section 4.

### 2. Preliminaries

Unless otherwise mentioned, $G$ will always denote a finite, simple and undirected graph with vertex set $V(G)$ and edge set $E(G)$. Any graph-theoretic term and notation not defined here are explained in [6].

A vertex is called central in $G$ if the greatest distance to any other vertex is minimal. It is well known that a finite tree $T$ has either a unique central vertex or precisely two central adjacent vertices $v$ and $w$. In the second case $vw$ is called a central edge. For a vertex or edge to be central is obviously a property invariant under automorphisms of $G$.

Let us recall some notations from [2].

#### 2.1. Separations.

An ordered pair $(A, B)$ of subsets of $V(G)$ is a separation of $G$ if $A \cup B = V(G)$ and if there is no edge $e = vw \in E(G)$ with $v \in A \setminus B$ and $w \in B \setminus A$. The cardinality $|A \cap B|$ of the separator $A \cap B$ of a separation $(A, B)$ is the order of $(A, B)$ and a separation of order $k$ is a $k$-separation.

A separation $(A, B)$ is proper if neither $A \subseteq B$ nor $B \subseteq A$. Otherwise $(A, B)$ is improper. A separation $(A, B)$ is tight if every vertex in $A \cap B$ has a neighbour in $A \setminus B$ and a neighbour in $B \setminus A$.

The set of separations of $G$ is partially ordered via

$$(A, B) \leq (C, D) : \iff A \subseteq C \land D \subseteq B.$$ 

For no two proper separations $(A, B)$ and $(C, D)$, the separation $(A, B)$ is $\leq$-comparable with $(C, D)$ and $(D, C)$. In particular we obtain that $(A, B)$ and $(B, A)$ are not $\leq$-comparable.

A separation $(A, B)$ is nested with a separation $(C, D)$ if $(A, B)$ is $\leq$-comparable with either $(C, D)$ or $(D, C)$. Since

$$(A, B) \leq (C, D) \iff (D, C) \leq (B, A),$$

being nested is symmetric and reflexive. Separations that are not nested are called crossing.
A separation \((A, B)\) is nested with a set \(S\) of separations if \((A, B)\) is nested with every \((C, D)\) \(\in\ S\). A set \(S\) of separations is nested with a set \(S'\) of separations if every \((A, B)\) \(\in\ S\) is nested with \(S'\) or equivalently every \((C, D)\) \(\in\ S'\) is nested with \(S\).

A set \(N\) of separations is nested if its elements are pairwise nested. A set \(S\) of separations is symmetric if for every \((A, B)\) \(\in\ S\) it also contains its inverse separation \((B, A)\). A symmetric set \(S\) of separations is also called a separation system or a system of separations, and if all its separations are proper, \(S\) is called a proper separation system.

For a set \(S\) of separations the separation system generated by \(S\) is the separation system consisting of the separations in \(S\) and their inverses. A set \(S\) of separations is canonical if it is invariant under the automorphisms of \(G\), i.e. for every \((A, B)\) \(\in\ S\) and for every \(\varphi \in \text{Aut}(G)\) we obtain \((\varphi[A], \varphi[B])\) \(\in\ S\).

For \(k \in \mathbb{N}\) let \(S_{<k}\) denote the set of separations of order less than \(k\) of \(G\). The \((<k)\)-inseparable sets are the \(S_{<k}\)-inseparable sets. So the \(k\)-blocks are exactly the \(S_{<k}\)-blocks of size at least \(k\).

For two separations \((A, B)\) and \((C, D)\) not equal to \((V(G), V(G))\) consider a cross-diagram as in Figure 1. Every pair \((X, Y)\) \(\in\ \{A, B\} \times \{C, D\}\) denotes a corner of this cross-diagram, which we also denote by cor\((X, Y)\). Let \(\overline{X} \in \{A, B\} \setminus \{X\}\) and \(\overline{Y} \in \{C, D\} \setminus \{Y\}\). In the diagram we consider the center \(c := A \cap B \cap C \cap D\) and for a corner cor\((X, Y)\) as above the interior \(\text{int}(X, Y) := (X \cap Y) \setminus (\overline{X} \cup \overline{Y})\) and the links \(\ell_X := (X \cap Y \cap \overline{Y}) \setminus c\) and \(\ell_Y := (Y \cap X \cap \overline{X}) \setminus c\). The vertex set \(X \cap Y\) is the disjoint union of \(\text{int}(X, Y)\) with \(\ell_X, \ell_Y\) and \(c\) and thus can be associated with the corner cor\((X, Y)\).

**Figure 1.** cross-diagram for \((A, B)\) and \((C, D)\)

**Remark 2.1.** Two separations \((A, B)\) and \((C, D)\) are nested, if and only if for one of their corners cor\((X, Y)\) the interior \(\text{int}(X, Y)\) and its links \(\ell_X\) and \(\ell_Y\) are empty. □
For a corner \( \text{cor}(X, Y) \) there is a corner separation \( (X \cap Y, X \cup Y) \), which is again a separation of \( G \).

**Lemma 2.2.** [4, Lemma 2.2] For two crossing separations \((A, B)\) and \((C, D)\) any of its corner separation is nested with every separation that is nested with both \((A, B)\) and \((C, D)\).

In particular a corner separation is nested with \((A, B)\), \((C, D)\) and all corner separations. A double counting argument yields:

**Remark 2.3.** For any two separations \((A, B)\) and \((C, D)\), the orders of the separations \((A \cap C, B \cup D)\) and \((B \cap D, A \cup C)\) sum to \(|A \cap B| + |C \cap D|\). □

### 2.2. Tree-decompositions

Recall that a tree-decomposition \( \mathcal{T} \) of \( G \) is a pair \((T, (P_t)_{t \in V(T)})\) of a tree \( T \) and a family of vertex sets \( P_t \subseteq V(G) \) for every node \( t \in V(T) \), such that

- \((T1)\) \( V(G) = \bigcup_{t \in V(T)} P_t \);
- \((T2)\) for every edge \( e \in E(G) \) there is a node \( t \in V(T) \) such that both end vertices of \( e \) lie in \( P_t \);
- \((T3)\) whenever \( t_2 \) lies on the \( t_1 - t_3 \) path in \( T \) we obtain \( P_{t_1} \cap P_{t_2} \subseteq P_{t_2} \).

The sets \( P_t \) are the parts of \( \mathcal{T} \). For an edge \( tt' \in E(T) \) the intersection \( P_t \cap P_{t'} \) is the corresponding adhesion set and the maximum size of an adhesion set of \( \mathcal{T} \) is the adhesion of \( \mathcal{T} \). A node \( t \in V(T) \) is a hub node if the corresponding part \( P_t \) is a subset of \( P_{t'} \) for some neighbour \( t' \) of \( t \). If \( t \) is a hub node, then \( P_t \) is a hub. A tree-decomposition \( \mathcal{T} = (T, (P_t)_{t \in V(T)}) \) of \( G \) and a tree-decomposition \( \mathcal{T}' = (T', (P'_t)_{t \in V(T')}) \) of \( G' \) are isomorphic if there is an isomorphism \( \varphi : G \to G' \) and an isomorphism \( \psi : T \to T' \) such that for every part \( P_t \) of \( \mathcal{T} \) we obtain \( \varphi[P_t] = P'_{\psi(t)} \). We say \( \varphi \) induces an isomorphism between \( \mathcal{T} \) and \( \mathcal{T}' \). A tree-decomposition \( \mathcal{T} \) is canonical if it is invariant under the automorphisms of \( G \), i.e. every automorphism of \( G \) induces an automorphism of \( \mathcal{T} \).

Let \((T, (P_t)_{t \in V(T)})\) be a tree-decomposition of \( G \). For \( t \in V(T) \) the torso \( H_t \) is the graph obtained from \( G[P_t] \) by adding all edges joining two vertices in a common adhesion set \( P_t \cap P_u \) for any \( tu \in E(T) \). A separation \((A, B)\) of \( G[P_t] \) is a separation of \( H_t \) if and only if it does not separate any adhesion set \( P_t \cap P_{t'} \) for \( tt' \in E(T) \). A separation \((A, B)\) of \( G \) with \( A \cap B \subseteq P_t \) for some node \( t \in V(T) \) that does not separate any adhesion set \( P_t \cap P_{t'} \) for \( tt' \in E(T) \) induces the separation \((A \cap P_t, B \cap P_t)\) of \( H_t \).

Every oriented edge \( \vec{e} = t_1t_2 \) of \( T \) divides \( T - e \) in two components \( T_1 \) and \( T_2 \) with \( t_1 \in V(T_1) \) and \( t_2 \in V(T_2) \). By [3] Lemma 12.3.1 \( \vec{e} \) induces the separation \( \left( \bigcup_{t \in V(T_1)} P_t, \bigcup_{t \in V(T_2)} P_t \right) \) of \( G \) such that the separator coincides with the adhesion set \( P_{t_1} \cap P_{t_2} \). We say a separation is induced by \( \mathcal{T} \) if it is induced by an oriented edge of \( T \).

The set of separations induced by a tree-decomposition \( \mathcal{T} \) (of adhesion less than \( k \)) is a nested system \( N(\mathcal{T}) \) of separations (of order less than \( k \)). We say \( N(\mathcal{T}) \) is induced by \( \mathcal{T} \). Clearly if \( \mathcal{T} \) is canonical, then so is \( N(\mathcal{T}) \).
Remark 2.5. (i) Every element of a representation of Profiles.

2.3. Profiles. Let $s$ be a separation system. A subset $O \subseteq s$ is an orientation of $s$ if for every $(A, B) \in s$ exactly one of $(A, B)$ and $(B, A)$ is an element of $O$. An orientation $O$ of $s$ is consistent if for every $(A, B), (C, D) \in s$ with $(A, B) \in O$ and $(C, D) \subseteq (A, B)$ we obtain $(C, D) \in O$ as well. A consistent orientation $P$ of $S_{S_{<K}}$ is called a $k$-profile if it satisfies

(P) for all $(A, B), (C, D) \in P$ we have $(B \cap D, A \cup C) \notin P$.

In particular if the order $|(A \cup C) \cap (B \cap D)|$ of this corner separation is less than $k$, we have $(A \cup C, B \cap D) \notin P$. Sometimes we omit the $k$ and call $P$ a profile.

It is easy to check that every $k$-block $b$ induces a $k$-profile via

$$P_k(b) := \{(A, B) \in S_{S_{<K}} \mid b \subseteq B\}.$$ 

Also tangles of order $k$ (or $k$-tangles), as introduced by Robertson and Seymour [5], are $k$-profiles. For more background on profiles, see [7].

For $r \in \mathbb{N}$, a $k$-profile $P$ is $r$-robust if for any $(A, B) \in P$ and any $(C, D) \in S_{S_{<r+1}}$, one of $(A \cup C, B \cap D)$, $(A \cup D, B \cap C)$ either has order at least $k - 1$, or is in $P$. If $P$ is $r$-robust for all $r \in \mathbb{N}$, then we call $P$ robust.

A robust $k$-profile $P$ is maximal if there does not exist a robust $\ell$-profile $Q$ with $P \subsetneq Q$ and $\ell > k$. Then $P$ is just called a maximal robust profile.

Remark 2.5. (i) Every $k$-profile is $\ell$-robust for all $\ell < k$;

(ii) if a $k$-block $b$ contains a complete graph on $k$ vertices, then the induced $k$-profile $P_k(b)$ is robust. \hfill $\square$

The next lemma basically states that every $k$-profile induces a $k$-haven, as introduced by Seymour and Thomas [9].

Lemma 2.6. Let $X \subseteq V(G)$ with $|X| < k$ and let $Q$ be a $k$-profile. Then there exists a component $C \subseteq G - X$ such that $(V(G) \cap C, C \cup X) \in Q$.

Furthermore, $(V(G) \cap C, C \cup N(C)) \in Q$ as well.

Proof. Let $C_1, \ldots, C_n$ denote the components of $G - X$ and for $i \in \{1, \ldots, n\}$ let $(A_i, B_i) := (V(G) \cap C_i, C_i \cup X)$. To reach a contradiction suppose that $(B_i, A_i) \in Q$ for all $i \in \{1, \ldots, n\}$. Then (P) yields inductively for all $m < n$.

\hfill $\square$

In the original paper this theorem is stated without the canonicity since it holds in a greater generality. But it is clear from the proof that if $N$ is canonical, then so is $T(N)$. \hfill $\square$
that \((\bigcup_{i \leq m} B_i, \bigcap_{i \leq m} A_i) \in Q\), since their separators all equal \(X\). Hence for \(m = n\), we obtain \((V(G), X) \in Q\), contradicting the consistency of \(Q\) with \((X, V(G)) \leq (V(G), X)\). Thus there is a component \(C\) of \(G - X\) such that \((A, B) := (V(G) \setminus C, C \cup X) \in Q\).

Now suppose \((C \cup N(C), V(G) \setminus C) \in Q\). Then \((P)\) with \((A, B)\) yields that \((V(G) \setminus C) \cup C \cup N(C), (C \cup X) \cap (V(G) \setminus C) = (V(G), X) \in Q\), contradicting the consistency of \(Q\) again. \(\Box\)

A \(k\)-profile \(Q\) inhabits a part \(P_t\) of a tree-decomposition \(T, (P_t)_{t \in V(T)}\) if for every \((A, B) \in Q\) we obtain that \((B \setminus A) \cap P_t\) is not empty. Note that if for a node \(t\) every separation induced by an oriented edge \(ut\) of \(T\) has order less than \(k\), then \(Q\) inhabits \(P_t\) if and only if all those separations are in \(Q\).

**Corollary 2.7.** Let \((T, (P_t)_{t \in V(T)})\) be a tree-decomposition and let \(Q\) be a \(k\)-profile. If \(Q\) inhabits a part \(P_t\), then \(|P_t| \geq k\).

**Proof.** Our aim is to show that if \(|P_t| < k\), then any \(k\)-profile \(Q\) does not inhabit \(P_t\). By Lemma 2.6 there is a component \(C\) of \(G - P_t\) such that \((V(G) \setminus C, C \cup P_t) \in Q\). Since \((C \cup P_t) \setminus (V(G) \setminus C) = C\) and since \(C \cap P_t\) is empty, we obtain that \(Q\) does not inhabit \(P_t\). \(\Box\)

A set \(\mathcal{P}\) of profiles is canonical if for every \(P \in \mathcal{P}\) and every automorphism \(\varphi\) of \(G\) the profile \(\{(\varphi[A], \varphi[B]) \mid (A, B) \in P\}\) is also in \(\mathcal{P}\).

Two profiles \(P\) and \(Q\) are distinguishable if there is a separation \((A, B)\) with \((A, B) \in P\) and \((B, A) \in Q\). Such a separation distinguishes \(P\) and \(Q\). It is said to distinguish \(P\) and \(Q\) efficiently if its order \(|A \cap B|\) is minimal among all separations distinguishing \(P\) and \(Q\). A set \(\mathcal{P}\) of profiles is distinguishable if every two distinct \(P, Q \in \mathcal{P}\) are distinguishable. A tree-decomposition \(T\) distinguishes two profiles \(P\) and \(Q\) (efficiently) if some \((A, B)\) induced by \(T\) distinguishes them (efficiently).

For our main result of this paper, we will build on the following theorem.

**Theorem 2.8.** \cite{7} Theorem 2.6\footnote{Since \cite{7} is unpublished, see also \cite{3} Theorem 6.3 for a version just concerning robust blocks or \cite{1} Theorem 9.2 for a version also dealing with infinite graphs.} Every graph \(G\) has a canonical tree-decomposition of adhesion less than \(k\) that distinguishes every two distinguishable \((k - 1)\)-robust \(\ell\)-profiles of \(G\) for some values \(\ell \leq k\) efficiently. Moreover, every separation induced by the tree-decomposition distinguishes some of those profiles efficiently.

3. Construction methods

3.1. **Sticking tree-decompositions together.** Given a tree-decomposition \(T\) of \(G\) and for each torso \(H_t\) a tree-decomposition \(T^t\), our aim is to construct a new tree-decomposition \(\overline{T}\) of \(G\) by gluing together the tree-decompositions \(T^t\) of the torsos along \(T\) in a canonical way.
Example 3.1. First we shall give the construction of $\mathcal{T}$ for a particular example: $G$ is obtained from three edge-disjoint triangles intersecting in a single vertex by identifying two other vertices of distinct triangles. The tree-decomposition $\mathcal{T}$ of $G$ and the tree-decompositions of the torsos are depicted in Figure 2(a). In order to stick the tree-decompositions of the torsos together in a canonical way, we first have to refine them, see Figure 2(b).

![Figure 2](image_url)

Figure 2. (a) shows the tree-decomposition $\mathcal{T}$ of $G$, drawn in black, and the tree-decompositions of the torsos, drawn in grey. (b) shows the canonically glued tree-decomposition $\mathcal{T}$.

Before we can construct $\mathcal{T}$, we need some preparation.

Construction 3.2. Given a tree-decomposition $\mathcal{T} = (T, (P_t)_{t \in V(T)})$ of $G$, we construct a new tree-decomposition $\hat{T} = (\hat{T}, (P_t)_{t \in V(\hat{T})})$ of $G$ by contracting every edge $tu$ of $T$ where $P_t = P_u$\(^3\). In this tree-decomposition two adjacent nodes never have the same part. Let $F \subseteq E(\hat{T})$ be the set of edges $tu$ where neither $P_t \subseteq P_u$ nor $P_u \subseteq P_t$. By subdividing every edge $tu \in F$ and assigning to the subdivided node $x$ the part $P_x := P_t \cap P_u$, we obtain a new tree-decomposition $\hat{\mathcal{T}} = (\hat{T}, (P_t)_{t \in V(\hat{T})})$.

Remark 3.3. $\hat{T}$ defined as in Construction 3.2 satisfies the following:

(i) every separation induced by $\hat{T}$ is also induced by $\mathcal{T}$;
(ii) for every edge $tu \in E(T)$ that induces a separation not induced by $\hat{T}$ we have $P_t = P_u$;
(iii) for every edge $tu \in E(\hat{T})$ precisely one of $P_t$ or $P_u$ is a proper subset of the other;
(iv) if $\mathcal{T}$ distinguishes two profiles $Q_1$ and $Q_2$ efficiently, then so does $\hat{T}$;
(v) if $\mathcal{T}$ is canonical, then $\hat{T}$ is canonical as well. \hfill \Box

Lemma 3.4. Let $K$ be a complete subgraph of $G$ and $\hat{T}$ as in Construction 3.2. Then there is a node $t$ of $\hat{T}$ with $V(K) \subseteq P_t$ such that $P_t$ is fixed by every automorphism of $G$ fixing $K$.

\(^3\)Here we understand the nodes of $\hat{T}$ to be nodes of $T$, where a node obtained through the contraction of an edge $tu$ to be identified with either $t$ or $u$. 
Proof. As $K$ is complete, there is a node $u \in V(\hat{\mathcal{T}})$ with $V(K) \subseteq P_u$.

Let $W$ be the subforest of nodes $w$ with $K \subseteq P_w$, which is connected as $\hat{\mathcal{T}}$ is a tree-decomposition. Now $W$ either has a central vertex $t$ or a central edge $tu$ such that $P_u$ is a proper subset of $P_t$ (cf Remark 3.3(iii)). In both cases $P_t$ is fixed by the automorphisms of $G$ that fix $K$. □

**Construction 3.5.** Let $\mathcal{T} = (T, (P_t)_{t \in V(T)})$ be a tree-decomposition of $G$. For each $t \in V(T)$ let $\mathcal{T}^t = (T^t, (P^t_u)_{u \in V(T^t)})$ be a tree-decomposition of the torso $H_t$. For each $\mathcal{T}^t$ let $\hat{\mathcal{T}}^t$ be as in Construction 3.2. For $e = tu \in E(T)$ let $A_e$ denote the adhesion set $P_t \cap P_u$. Since $H_t[A_e]$ is complete, we can apply Lemma 3.4: there is a node $\gamma(t,u)$ of $\hat{\mathcal{T}}^t$ with $A_e \subseteq P^t_{\gamma(t,u)}$ such that $P^t_{\gamma(t,u)}$ is fixed by every automorphism of $H_t$ fixing $K$.

We obtain a tree $\mathcal{T}$ from the disjoint union of the trees $\hat{\mathcal{T}}^t$ for all $t \in V(T)$ by adding the edges $\gamma(t,u)\gamma(u,t)$ for each $tu \in E(T)$. Let $\mathcal{P}_u$ be $P_u^t$ for the unique $t \in V(T)$ with $u \in V(\hat{\mathcal{T}}^t)$. Then $\mathcal{T} := (T, (\mathcal{P}_t)_{t \in V(\hat{\mathcal{T}}^t)})$ is a tree-decomposition of $G$.

Two torsos $H_t$ and $H_u$ of $\mathcal{T}$ are *similar* if there is an automorphism of $G$ that induces an isomorphism between $H_t$ and $H_u$. The family $(\mathcal{T}^t)_{t \in V(T)}$ is *canonical* if all the $\mathcal{T}^t$ are canonical and for any two similar torsos $H_t$ and $H_u$ of $\mathcal{T}$ every automorphism of $G$ that witnesses the similarity of $H_t$ and $H_u$ induces an isomorphism between $\mathcal{T}^t$ and $\mathcal{T}^u$.

**Lemma 3.6.** The tree-decomposition $\mathcal{T}$ as in Construction 3.5 satisfies the following:

(i) for $t \in V(T)$ every node $u \in V(T^t)$ is also a node of $\mathcal{T}$ and $\mathcal{P}_u = P^t_u$;

(ii) every node $u \in V(\hat{\mathcal{T}})$ that is not a node of any $T^t$ is a hub node;

(iii) every separation $(A,B)$ induced by $\mathcal{T}$ is either induced by $\mathcal{T}$ or there is a node $t \in V(T)$ such that $(A \cap P_t, B \cap P_t)$ is induced by $\mathcal{T}^t$;

(iv) every separation induced by $\mathcal{T}$ is also induced by $\mathcal{T}$;

(v) for every separation $(C,D)$ induced by $\hat{\mathcal{T}}^t$ there is a separation $(A,B)$ induced by $\mathcal{T}^t$ such that $A \cap B \subseteq P_t$ and $(A \cap P_t, B \cap P_t) = (C,D)$;

(vi) if $\mathcal{T}$ and the family of the $\mathcal{T}^t$ are canonical, then $\mathcal{T}$ is canonical.

Proof. Whilst (i) is true by construction, the nodes added in the construction of $\hat{\mathcal{T}}^t$ are hub nodes by definition, yielding (ii). Furthermore, (iii), (iv) and (v) follow by construction with Remark 3.3(i) and the observation that for all $tu \in E(T)$ the adhesion sets $\overline{P}_{\gamma(t,u)} \cap \overline{P}_{\gamma(u,t)}$ and $P_t \cap P_u$ are equal. Finally, (iv) follows with Remark 3.3(v) and Lemma 3.4 from the construction. □

### 3.2. Obtaining tree-decompositions from almost nested sets of separations.

Theorem 2.4 gives a way how to transform a nested set of separations into a tree-decomposition. In this subsection, we extend this to sets of ‘almost nested’ separations.
For a separation \((A, B)\) of \(G\) and \(X \subseteq V(G)\), the pair \((A \cap X, B \cap X)\) is a separation of \(G[X]\), which we call the \textit{restriction} \((A, B)|X\) of \((A, B)\) to \(X\). Note that \((A, B)|X\) is proper if and only if \((A, B)\) separates \(X\). The \textit{restriction} \(S|X\) to \(X\) of a set \(S\) of separations of \(G\) to \(X\) consists of the proper separations \((A, B)|X\) with \((A, B) \in S\).

For a set \(S\) of separations of \(G\) let \(\min_{\text{ord}}(S)\) denote the set of those separations in \(S\) with minimal order. Note that if \(S\) is non-empty, then so is \(\min_{\text{ord}}(S)\), and that \(\min_{\text{ord}}\) commutes with graph isomorphisms.

A finite sequence \((\beta_0, \ldots, \beta_n)\) of vertex sets of \(G\) is called an \textit{S-focusing sequence} if

\((F1)\) \(\beta_0 = V(G)\);
\((F2)\) for all \(i < n\), the separation system \(N_{\beta_i}\) generated by \(\min_{\text{ord}}(S|\beta_i)\) is non-empty and is nested with the set \(S|\beta_i\);
\((F3)\) \(\beta_{i+1}\) is an \(N_{\beta_i}\)-block of \(G[\beta_i]\).

An \textit{S-focusing sequence} \((\beta_0, \ldots, \beta_n)\) is \textit{good} if

\((F^*)\) the separation system \(N_{\beta_n}\) generated by \(\min_{\text{ord}}(S|\beta_n)\) is nested with the set \(S|\beta_n\).

Note that for an \textit{S-focusing sequence} \((\beta_0, \ldots, \beta_n)\) we obtain \(\beta_n \subseteq \beta_{n-1} \subseteq \ldots \subseteq \beta_0\). The set of all \(S\)-focusing sequences is partially ordered by extension, where \((V(G))\) is the smallest element. The subset \(\mathcal{F}_S\) of all good \(S\)-focusing sequences is downwards closed in this partial order.

**Lemma 3.7.** Let \((\beta_0, \ldots, \beta_n) \in \mathcal{F}_S\) and let \((A, B) \in S\). If \((A, B)|\beta_n\) is proper, then \(A \cap B \subseteq \beta_n\).

**Proof.** By assumption \((A, B)|\beta_n\) is proper, hence there are \(a \in (\beta_n \cap A) \setminus B\) and \(b \in (\beta_n \cap B) \setminus A\). Since \(\beta_n \subseteq \beta_i\) for all \(i \leq n\) the separations \((A, B)|\beta_i\) are proper as well. Suppose for a contradiction there is a vertex \(v \in (A \cap B) \setminus \beta_n\). Let \(j < n\) be maximal with \(v \in \beta_j\). Since \(\beta_{j+1}\) is an \(N_{\beta_j}\)-block of \(G[\beta_j]\), there is a separation \((C, D) \in N_{\beta_j}\) with \(v \in C \setminus D\) and \(\{a, b\} \subseteq \beta_n \subseteq \beta_{j+1} \subseteq D\).

Now \(a, b\) and \(v\) witness that \((A, B)|\beta_j\) and \((C, D)\) are not nested: Indeed, \(a\) witnesses that \(D\) is not a subset of \(B \cap \beta_j\). Similarly, \(b\) witnesses that \(D\) is not a subset of \(A \cap \beta_j\). But \(v\) witnesses that neither \(A \cap \beta_j\) nor \(B \cap \beta_j\) is a subset of \(D\). Thus we get a contradiction to the assumption that \(N_{\beta_j}\) is nested with the set \(S|\beta_j\). \(\square\)

A set \(S\) of separations of \(G\) is \textit{almost nested} if all \(S\)-focusing sequences are good. In this case the maximal elements of \(\mathcal{F}_S\) in the partial order are exactly the \(S\)-focusing sequences \((\beta_0, \ldots, \beta_n)\) with \(N_{\beta_n} = \emptyset\), and hence \(S|\beta_n = \emptyset\).

**Lemma 3.8.** Let \(S\) be an \textit{almost nested set} of separations of \(G\).

(i) If \((\beta_0, \ldots, \beta_n) \in \mathcal{F}_S\) is maximal, then \(\beta_n\) is an \(S\)-block.

(ii) If \(b\) is an \(S\)-block, there is a maximal \((\beta_0, \ldots, \beta_n) \in \mathcal{F}_S\) with \(\beta_n = b\).

**Proof.** Let \((\beta_0, \ldots, \beta_n) \in \mathcal{F}_S\) be maximal. Then \(S|\beta_n\) is empty, i.e. no \((A, B) \in S\) induces a proper separation of \(G[\beta_n]\). Hence \(\beta_n\) is \(S\)-inseparable.
For every \( v \in V(G) \setminus \beta_n \) there is an \( i < n \) and a separation in \( N_{\beta_i} \) separating \( v \) from \( \beta_n \). Hence \( \beta_n \) is an \( S \)-block.

Conversely given an \( S \)-block \( b \), let \((\beta_0, \ldots, \beta_n) \in F_S\) be maximal with the property \( b \subseteq \beta_n \), which exists since \((V(G)) \in F_S\) and since \( F_S \) is finite. Since \( b \) is \( N_{\beta_n} \)-inseparable, there is some \( N_{\beta_n} \)-block \( \beta_{n+1} \) containing \( b \). The choice of \((\beta_0, \ldots, \beta_n)\) implies that \((\beta_0, \ldots, \beta_{n+1}) \notin F_S\) and hence \( N_{\beta_n} = \emptyset \), i.e. \((\beta_0, \ldots, \beta_n)\) is a maximal element of \( F_S \). Thus \( \beta_n \) is an \( S \)-block with \( b \subseteq \beta_n \) and hence \( b = \beta_n \).

**Construction 3.9.** Let \( S \) be an almost nested set of separations of \( G \). We recursively construct for every \( S \)-focusing sequence \((\beta_0, \ldots, \beta_n)\) a tree-decomposition \( T^{\beta_n} \) of \( G[\beta_n] \) so that the tree-decomposition \( T^{V(G)} = T(S) \) for the smallest \( S \)-focusing sequence \((V(G))\) is a tree-decomposition of \( G \).

For each maximal \( S \)-focusing sequence \((\beta_0, \ldots, \beta_m)\) we take the trivial tree-decomposition of \( G[\beta_m] \) with only a single part. Suppose that \( T^\beta \) has already been defined for every successor \((\beta_0, \ldots, \beta_n, \beta)\) of \((\beta_0, \ldots, \beta_n)\). To define \( T^{\beta_n} \) we start with the tree-decomposition \( T(N_{\beta_n}) \) of \( G[\beta_n] \) as given by Theorem 2.4. For each hub node \( h \) we take the trivial tree-decomposition of \( H_h \) and for each node \( t \) whose part is an \( N_{\beta_n} \)-block \( \beta \), we take \( T^\beta \) given from the \( S \)-focusing sequence \((\beta_0, \ldots, \beta_n, \beta)\). This indeed is a tree-decomposition of the torso \( H_t \), which we will show in Theorem 3.10. Hence we can apply Construction 3.5 to \( T(N_{\beta_n}) \) and the family of tree-decompositions of the torsos to get \( T^{\beta_n} \).

Given an \( S \)-focusing sequence \((\beta_0, \ldots, \beta_n)\), any two separations in \( N_{\beta_n} \) have the same order \( \ell \). We call \( \ell \) the rank of \((\beta_0, \ldots, \beta_n)\). If \( N_{\beta_n} \) is empty, we set the rank to be \( \infty \).

For an almost nested set \( S \) of separations of \( G \) two \( S \)-focusing sequences \((\beta_0, \ldots, \beta_n)\) and \((\alpha_0, \ldots, \alpha_m)\) are similar if there is an automorphism \( \psi \) of \( G \) inducing an isomorphism between \( G[\beta_n] \) and \( G[\alpha_m] \). Similar \( S \)-focusing sequences clearly have the same rank. If \( S \) is canonical, then \( \psi \) induces an isomorphism between \( T(N_{\beta_n}) \) and \( T(N_{\alpha_m}) \) as obtained from Theorem 2.4.

**Theorem 3.10.** The tree-decomposition \( T(S) \) as in Construction 3.9 is well-defined and satisfies the following:

(i) every \( S \)-block of \( G \) is a part of \( T(S) \);
(ii) every part of \( T(S) \) is either an \( S \)-block of \( G \) or a hub;
(iii) for every separation \((A, B)\) induced by \( T(S) \) there is a separation \((A', B') \subseteq S\) such that \( A \cap B = A' \cap B' \);
(iv) if \( S \) is canonical, then so is \( T(S) \).

**Proof.** We show inductively that for any \( S \)-focusing sequence \((\beta_0, \ldots, \beta_n)\) the tree-decomposition \( T^{\beta_n} \) has the following properties:

(a) every \( S \)-block included in \( \beta_n \) is a part of \( T^{\beta_n} \);
(b) every part of \( T^{\beta_n} \) is either an \( S \)-block or a hub;
(c) every separation \((A, B)\) induced by \( T^{\beta_n} \) is proper.
(d) and for every separation \((A, B)\) induced by \(T_{\beta_n}\) there is a separation \((A', B') \in S\) and an \(S\)-focusing sequence \((\beta_0, \ldots, \beta) \geq (\beta_0, \ldots, \beta_n)\) such that \((A', B')|\beta = (A, B)\).

Furthermore we show for canonical \(S\) by induction, that

(e) if \((\alpha_0, \ldots, \alpha_m)\) and \((\beta_0, \ldots, \beta_n)\) are similar, then \(T_{\alpha_m}\) and \(T_{\beta_n}\) are isomorphic;

(f) \(T_{\beta_n}\) is canonical.

The tree-decompositions for the maximal \(S\)-focusing sequences satisfy (a) and (b) by Lemma \[3.8\] and (c) and (d) since their trees do not have any edges. If for two \(S\)-blocks \(b_1\) and \(b_2\) there is an isomorphism between \(G[b_1]\) and \(G[b_2]\) induced by an automorphism of \(G\), then clearly the tree-decompositions are isomorphic. Hence (e) and (f) hold for all \(S\)-focusing sequences of rank \(\infty\).

Suppose for our induction hypothesis that for every \(S\)-focusing sequence \((\alpha_0, \ldots, \alpha_m)\) with rank greater than \(r\) the tree-decomposition \(T_{\alpha_m}\) of \(G[\alpha_m]\) has the desired properties. Let \((\beta_0, \ldots, \beta_n)\) be an \(S\)-focusing sequence of rank \(r\). Then for each successor \((\beta_0, \ldots, \beta_n, \beta)\) the tree-decomposition \(T_{\beta}\) is indeed a tree-decomposition of the corresponding torso: for a separation \((A, B)\) induced by \(T_{\beta}\) consider \((A', B')\) as given in (d). By (F*) we obtain that \((A', B')|\beta_n = (A, B)\) is nested with \(N_{\beta_n}\), hence \((A, B)\) does not separate any adhesion set in \(H_t\). Hence \(T_{\beta_n}\) is indeed well-defined.

Lemma \[3.6\](i), (ii) and (iii) and the induction hypothesis yield (a), (b) and (c) for \(T_{\beta_n}\). Also by Lemma \[3.6\](iii) for a separation \((A, B)\) induced by \(T_{\beta_n}\) either \((A, B) \in N_{\beta_n} \subset \Gamma|\beta_n\) or \((A, B)\) induces a separation in \(T_{\beta}\) for an \(N_{\beta_n}\)-block \(\beta\) on the corresponding torso. In the first case \((\beta_0, \ldots, \beta_n)\) is the desired \(S\)-focusing sequence for (d) and in the second case the induction hypothesis yields \((A', B')\) \(S\)-blocks whose corresponding \(S\)-focusing sequences are similar and have rank greater than \(r\), or they are hubs. If they are \(N_{\beta_n}\)-blocks, the chosen tree-decompositions are isomorphic by the induction hypothesis. If they are hubs, the chosen trivial tree-decompositions are isomorphic as witnessed by every automorphism of \(G\) witnessing the similarity of \(H_t\) and \(H_u\). Hence this family of tree-decompositions of the torsos of \(T(N_{\beta_n})\) is canonical and with Lemma \[3.6\](vi) we get (f).

Inductively the tree-decomposition \(T(V(G)) = T(S)\) of \(G\) satisfies (i), (ii) and (iv) by (a), (b) and (f). Finally, (iii) follows from (c), (d) and Lemma \[3.7\]
3.3. Extending a nested set of separations. In this subsection we give a condition for when we can extend a nested set of separations so that it distinguishes any two distinguishable profiles in a given set \( \mathcal{P} \) efficiently.

Let \( N \) be a nested separation system of \( G \) and \( T(N) = (T, (P_t)_{t \in V(T)}) \) be the tree-decomposition of \( G \) as in Theorem 2.4. Recall that a separation \((A, B)\) of \( G \) nested with \( N \) induces a separation \((A \cap P_t, B \cap P_t)\) of each torso \( H_t \). An \( \ell \)-profile \( Q \) of \( H_t \) is induced by a \( k \)-profile \( Q \) of \( G \) if for every \((A', B') \in Q\) there is an \((A, B) \in \mathcal{P}\) which induces \((A', B')\) on \( H_t \).

**Construction 3.11.** Let \( t \in V(T) \) and let \( Q \) be a \( k \)-profile of \( G \). We construct a profile \( \tilde{Q}^t \) of the torso \( H_t \) which is induced by \( Q \).

**Case 1:** \( Q \) inhabits \( P_t \).

Let \((A, B)\) be a proper separation of \( H_t \) of order less than \( k \). By Lemma 2.6 there is a unique component \( C \) of \( G - (A \cap B) \) with \((V(G) \setminus C, C \cup N(C)) \in Q \).

As \( Q \) is consistent and inhabits \( P_t \), the set \( C \cap P_t \) is non-empty and either a subset of \( A \cap B \) or \( B \setminus A \), but not both. If \((C \cap P_t) \subseteq (B \setminus A)\), then we let \((A, B) \in \tilde{Q}^t \). Otherwise we let \((B, A) \in \tilde{Q}^t \).

**Case 2:** \( Q \) does not inhabit \( P_t \) and \((V(G) \setminus C, C \cup N(C)) \notin Q \) for all components \( C \) of \( G - P_t \).

Let \((A, B)\) be a proper separation of \( H_t \) of order less than \( k \). By Lemma 2.6 there is a unique component \( C \) of \( G - (A \cap B) \) with \((V(G) \setminus C, C \cup N(C)) \in Q \).

Since \( C \) is not a component of \( G - P_t \), the set \( C \cap P_t \) is non-empty by assumption, and we define \( \tilde{Q}^t \) as above.

**Case 3:** \( Q \) does not inhabit \( P_t \) and there is a component \( C \) of \( G - P_t \) such that \((V(G) \setminus C, C \cup N(C)) \in Q \).

Let \( m \) denote the size of the neighbourhood of \( C \). Let \( b \) be the \( m \)-block of \( H_t \) containing \( N(C) \). For \( \tilde{Q}^t \) we take the \( m \)-profile induced by \( b \).

The following is straightforward to check:

**Remark 3.12.** The set \( \tilde{Q}^t \) as in Construction 3.11 is a profile of \( H_t \) induced by \( Q \). Moreover, if \( Q \) is \( r \)-robust, then so is \( \tilde{Q}^t \). \( \square \)

The next remark is a direct consequence of the relevant definitions.

**Remark 3.13.** Let \( Q_1 \) and \( Q_2 \) be profiles of \( G \).

(i) If a separation \((A, B)\) of \( G \) nested with \( N \) distinguishes \( Q_1 \) and \( Q_2 \) efficiently, then the induced separation \((A \cap P_t, B \cap P_t)\) of \( H_t \) distinguishes \( \tilde{Q}_1^t \) and \( \tilde{Q}_2^t \) efficiently for any part \( P_t \) where it is proper;

(ii) if a separation \((A, B)\) of some torso \( H_t \) distinguishes \( \tilde{Q}^t_1 \) and \( \tilde{Q}^t_2 \), then any separation of \( G \) that induces \((A, B)\) on \( H_t \) distinguishes \( Q_1 \) and \( Q_2 \). \( \square \)

**Lemma 3.14.** Let \( Q_1 \) and \( Q_2 \) be profiles of \( G \) which are not already distinguished efficiently by \( N \). Let \((A, B)\) distinguish them efficiently such that it is nested with \( N \). Then there is a part \( P_t \) of \( T(N) \) such that the induced separation \((A \cap P_t, B \cap P_t)\) of the torso \( H_t \) is proper.
Proof. Since \((A, B)\) is nested with \(N\), there is a part \(P_t\) such that \(A \cap B \subseteq P_t\). Suppose that \((A \cap P_t, B \cap P_t)\) is not proper. Without loss of generality let \((B \backslash A) \cap P_t\) be empty and let \((A, B) \in Q_1\).

By Lemma 2.6, we obtain a component \(K\) of \(G - (A \cap B)\) such that \((A, B) \subseteq (V(G) \backslash K, K \cup N(K)) \in Q_1\). By consistency of \(Q_2\) the separation \((V(G) \backslash K, K \cup N(K))\) still distinguishes \(Q_1\) and \(Q_2\), and since \((A, B)\) distinguishes \(Q_1\) and \(Q_2\) efficiently, the neighbourhood of \(K\) is \(A \cap B\). Let \(u\) be the neighbour of \(t\) such that the by \(tu\) induced separation \((C_t, D_t) \in N\) satisfies \(K \cup N(K) \subseteq D_t\). If \((B \backslash A) \cap P_u\) is empty, we obtain \((C_u, D_u) \in Q_1\) as before and by construction we obtain \((C_t, D_t) < (C_u, D_u)\).

Among all parts \(P_t\) containing \(A \cap B\) such that \((B \backslash A) \cap P_t\) is empty, we choose a part \(P_x\) such that \((C_x, D_x)\) is maximal with respect to the ordering of separations. Let \(y\) denote the neighbour of \(x\) such that \(xy\) induces \((C_x, D_x)\). There is a vertex \(v \in (C_x \cap D_x) \backslash (A \cap B)\), since otherwise \((C_x, D_x)\) would distinguish \(Q_1\) and \(Q_2\) efficiently. Since we assumed that \((B \backslash A) \cap P_x\) is empty, we deduce that \(v \in A \backslash B\). Therefore \((A \backslash B) \cap P_y\) is not empty. Hence if \((A \cap P_y, B \cap P_y)\) on \(H_y\) were improper, then \((B \backslash A) \cap P_y\) would be empty and \((C_y, D_y)\) would contradict the maximality of \((C_x, D_x)\).

For a nested separation system \(N\) let \(S_{<k}^N\) be the set of separations of order less than \(k\) of \(G\) nested with \(N\).

Construction 3.15. Let \(N \subseteq S_{<r+1}\) be a nested separation system of \(G\) and let \(\mathcal{P}\) be a set \(r\)-robust \(\ell\)-profiles of \(G\) for some values \(\ell \leq r + 1\), such that \(S_{<r+1}^N\) distinguishes any two distinguishable profiles in \(\mathcal{P}\) efficiently.

Let \(\mathcal{T}(N) = (T, (P_t)_{t \in V(T)})\) be as in Theorem 2.4 and let \(\mathcal{P}^t\) be the set of profiles \(\tilde{Q}_t^t\) of \(H_t\) for \(Q \in \mathcal{P}\). Applying Theorem 2.8 to the graphs \(H_t\) and the maximal \(k\) of any \(k\)-profile in \(\mathcal{P}^t\), we get a tree-decomposition \(T^t\) of \(H_t\) that distinguishes every two distinguishable profiles in \(\mathcal{P}^t\) efficiently. Note that if \(\mathcal{P}\) is canonical, then the family \((T^t)_{t \in V(T)}\) is canonical as well. By applying Lemma 3.6 we obtain a tree-decomposition \(\overline{T}\) and the corresponding nested system \(\overline{N}\) of separations of order at most \(r\) induced by \(T\).

Theorem 3.16. The nested separation system \(\overline{N}\) as in Construction 3.15 satisfies the following.

(i) \(N \subseteq \overline{N}\);

(ii) \(\overline{N}\) distinguishes every two distinguishable profiles in \(\mathcal{P}\) efficiently;

(iii) if \(N\) and \(\mathcal{P}\) are canonical, then so is \(\overline{N}\).

Proof. Lemma 3.6(iv) yields (i). For (ii), consider two distinguishable profiles \(Q_1, Q_2 \in \mathcal{P}\) not already distinguished efficiently by \(N\). By assumption, there is some \((A, B) \in S_{<r+1}^N\) distinguishing \(Q_1\) and \(Q_2\) efficiently.

By Lemma 3.14 and Remark 3.13(i) there is a part \(P_t\) of \(\mathcal{T}(N)\) such that \(\tilde{Q}_1^t\) and \(\tilde{Q}_2^t\) are distinguished efficiently by \((A \cap P_t, B \cap P_t)\). Hence Theorem 2.8, Remark 3.3(iv), Lemma 3.6(v) and Remark 3.13(ii) yield a separation of order \(|A \cap B|\) in \(\overline{N}\) distinguishing \(Q_1\) and \(Q_2\), yielding (ii).
Finally, (iii) holds by construction. □

4. Proof of the main result

Given a $k$-block $b$ and a component $C$ of $G - b$, then $(C \cup N(C), V(G) \setminus C)$ is a separation. By $S_k(b)$ we denote the set of all those separations. Note that $S_k(b)$ is a nested set of separations, while for different ($r$-robust) $k$-blocks $b$, $b'$ the union $S_k(b) \cup S_k(b')$ need not to be nested \[3\].

**Lemma 4.1.** Let $b$ be a $k$-block of $G$. Then $b$ is separable if and only if every separation in $S_k(b)$ has order less than $k$.

*Proof.* For the ‘only if’-implication, let $T = (T, (P_t)_{t \in V(T)})$ be a tree-decomposition of adhesion less than $k$ of $G$ with $P_t = b$ for some $t \in V(T)$. Let $C$ be a component of $G - b$. There is a separation $(A, B)$ induced by $T$ with $C \subseteq A \setminus B$ and $b \subseteq B$. Hence $N(C) \subseteq A \cap B$, and so has less than $k$ vertices.

For the ‘if’-implication, just consider the star-decomposition induced by $S_k(b)$, whose central part is $b$. This tree-decomposition has adhesion less than $k$ if and only if all separations in $S_k(b)$ have order less than $k$. □

**Remark 4.2.** Let $b$ be a $k$-block of $G$. For all $(A, B) \in S_k(b)$ the separator $A \cap B$ is a subset of $b$.

Given some $r \in \mathbb{N}$ and a set $\mathcal{B}$ of distinguishable \[4\] $r$-robust $k$-blocks for some values $k \leq r + 1$, we define

$$S(\mathcal{B}) := \bigcup \left\{ S_k(b) \cap S_{<k} \mid b \text{ is a } k\text{-block in } \mathcal{B} \right\}.$$ 

Note that if the set of profiles induced by $\mathcal{B}$ is canonical, then so is $S(\mathcal{B})$.

**Lemma 4.3.** Every separable $k$-block $b \in \mathcal{B}$ is an $S(\mathcal{B})$-block.

*Proof.* Suppose for a contradiction there is a $k'$-block $b' \in \mathcal{B}$ and a separation $(A, B) \in S_{k'}(b') \cap S_{<k'} \subseteq S(\mathcal{B})$ separating $b$. Consider a separation $(C, D)$ distinguishing $b$ and $b'$ efficiently with $b \subseteq C$ and $b' \subseteq D$. Since $|C \cap D| < k$, there is a vertex $v \in b \setminus (C \cap D)$. And since $A \cap B \subseteq b' \subseteq D$, the link $\ell_C$ is empty. Therefore we deduce that either $v \in A \setminus B$ or $v \in B \setminus A$. Let $w$ denote a vertex of $b$ such that $(A, B)$ separates $v$ and $w$. Both the corner separations $(A \cap C, B \cup D)$ and $(B \cap C, A \cup D)$ have order at most $|C \cap D| < k$. But one of them separates $v$ from $w$, contradicting the ($< k$)-inseparability of $b$. Hence $b$ is $S(\mathcal{B})$-inseparable.

Let $X$ be an $S(\mathcal{B})$-inseparable set including $b$ and let $v \in V(G) \setminus b$. Then there is some $(A, B) \in S_k(b)$ separating $b$ from $v$. Lemma 4.1 implies that $(A, B) \in S_k(b) \cap S_{<k} \subseteq S(\mathcal{B})$ and thus $v$ is not in $X$. Hence $X = b$. □

**Lemma 4.4.** Let $(A, B)$ and $(C, D)$ be tight separations of $G$ such that $A \setminus B$ is connected and the link $\ell_A$ is empty. Then $(A, B)$ and $(C, D)$ are nested.

\[4\] A set of blocks is distinguishable if the set of induced profiles is distinguishable.
Proof. Since \( A \setminus B \) is connected, either \( \text{int}(A, C) \) or \( \text{int}(A, D) \) is empty, say \( \text{int}(A, C) \). Thus there cannot be a vertex in the link \( \ell_C \) because it would have a neighbour in \( A \setminus B \), which is impossible. Hence \( (A, B) \) and \( (C, D) \) are nested by Remark 2.1. \( \square \)

Lemma 4.5. Let \( (A, B), (C, D) \in S(\mathcal{B}) \) be crossing. Then the links \( \ell_B \) and \( \ell_D \) are empty.

Moreover, the separation \( (K \cup N(K), V(G) \setminus K) \) for every component \( K \) of \( G[\text{int}(B, D)] \) is in \( S(\mathcal{B}) \) and its order is strictly less than the orders of both \( (A, B) \) and \( (C, D) \).

Proof. Let \( b_1 \) and \( b_2 \) be blocks in \( \mathcal{B} \) such that \( (A, B) \in S_{k_1}(b_1) \cap S_{<k_1} \) and \( (C, D) \in S_{k_2}(b_2) \cap S_{<k_2} \). We may assume that the order \( k_2 \) of \( b_2 \) is at most the order \( k_1 \) of \( b_1 \). By Lemma 4.4 there are vertices \( v_A \in \ell_A \) and \( v_C \in \ell_C \). By Remark 4.2 \( v_C \in b_1 \). As \( (C, D) \) cannot separate \( b_1 \), the block \( b_1 \) is contained in \( B \cap C \). In particular, the link \( \ell_D \) is empty.

Let \( X \) be a component of \( G - C \cap D \) that contains a vertex \( w \) of \( b_2 \). Note that \( X \) is unique as \( b_2 \) is a \( k_2 \)-block. As \( \ell_D \) is empty, \( X \) must be contained in \( D \cap A \) or \( D \cap B \). Since \( b_2 \) contains \( v_A \), it must be contained in \( D \cap A \). Indeed, otherwise the corner separation \( B \cap D \) would separated \( w \) from \( v_A \). Hence \( \ell_B \) is empty.

Let \( K \) be an arbitrary component of \( G[\text{int}(B, D)] \). Let \( E := K \cup N(K) \) and \( F := V(G) \setminus K \). Since the center \( c \) is a subset of \( b_1 \cap b_2 \) and since \( K \cap (b_1 \cup b_2) \) is empty, \( K \) is a component of both \( G - b_1 \) and \( G - b_2 \). Hence \( (E, F) \) is in both \( S_{k_1}(b_1) \) and \( S_{k_2}(b_2) \). And since \( E \cap F \subseteq c \) and since \( \ell_A \) and \( \ell_C \) are not empty, we deduce that \( |E \cap F| < \min\{|A \cap B|, |C \cap D|\} \).

Lemma 4.6. \( S(\mathcal{B}) \) is almost nested.

Proof. We have to show that every \( S(\mathcal{B}) \)-focusing sequence \( (\beta_0, \ldots, \beta_n) \) is good, i.e. \( N_{\beta_n} \) is nested with \( S(\mathcal{B}) \setminus \beta_n \). Let \( (\beta_0, \ldots, \beta_n) \) be an \( S(\mathcal{B}) \)-focusing sequence. Let \( (A, B) \setminus \beta_n \in N_{\beta_n} \) and \( (C, D) \setminus \beta_n \in S(\mathcal{B}) \setminus \beta_n \). If \( (A, B) \) and \( (C, D) \) are nested, then so are \( (A, B) \setminus \beta_n \) and \( (C, D) \setminus \beta_n \). Suppose \( (A, B) \) and \( (C, D) \) are crossing. By Lemma 4.5 \( \ell_B \) and \( \ell_D \) are empty. If \( \text{int}(B, D) \cap \beta_n \) is empty, then by Remark 2.1 \( (A, B) \setminus \beta_n \) and \( (C, D) \setminus \beta_n \) are nested. Hence by Lemma 4.3 it suffices to show that \( (E \setminus F) \setminus \beta_n \) is empty for every \( (E, F) \in S(\mathcal{B}) \) with \( E \subseteq B \cap D \) whose order is strictly smaller than the order of \( (A, B) \).

Since \( (A, B) \setminus \beta_n \) is proper, there is a \( v \in \beta_n \setminus B \subseteq \beta_n \setminus E \subseteq (F \setminus E) \cap \beta_n \). Since \( (A, B) \setminus \beta_n \) has minimal order among all separations in \( S(\mathcal{B}) \setminus \beta_n \), we deduce that \( (E, F) \setminus \beta_n \) is improper and hence either \( (F \setminus E) \cap \beta_n \) or \( (E \setminus F) \cap \beta_n \) is empty. Now \( v \) witnesses that \( (E \setminus F) \setminus \beta_n \) is empty, as desired. \( \square \)

Lemma 4.7. Given \( r \in \mathbb{N} \), let \( \mathcal{P} \) be a set of \( r \)-robust distinguishable \( k \)-profiles for some values \( k \leq r + 1 \). Let \( N \) be a nested separation system such that for every \( (C, D) \in N \), there is some \( \ell \)-profile in \( \mathcal{P} \) induced by an \( \ell \)-block \( b \) with \( (C \cap D) \subseteq b \). Then any two distinct \( P, Q \in \mathcal{P} \) are distinguished efficiently by a separation nested with \( N \).
Proof. Let \((A, B)\) distinguish \(P, Q \in \mathcal{P}\) efficiently such that the number of separations in \(N\) nested with \((A, B)\) is maximal. Without loss of generality let \((A, B) \in P\). Let \(k:=|A \cap B|\). We prove that \((A, B)\) is nested with \(N\).

Suppose for a contradiction that there is some \((C, D) \in N\) not nested with \((A, B)\). Let \(b\) be an \((\ell + 1)\)-block such that \((C \cap D) \subseteq b\) whose induced profile \(P_{\ell+1}(b)\) is in \(\mathcal{P}\).

**Case 1:** \(k < \ell\). Remark 4.2 implies that \(C \cap D\) is \((\leq \ell)\)-inseparable and hence one of the links \(\ell_A\) or \(\ell_B\) is empty. Without loss of generality let \(\ell_B\) be empty. The orders of the corner separations \((A \cup D, B \cap C)\) and \((A \cup C, B \cap D)\) are less or equal than \(|A \cap B|\). Hence they are oriented by \(P\) and \(Q\). Applying Lemma 2.6 to \(X := A \cap B\) and \(P\) yields a component \(K\) of \(G - X\) with \((V(G) \backslash K, K \cup N(K)) \in P\). In particular we get \(K \subseteq B \setminus A\) by consistency. Since \(\ell_B\) is empty and \(K\) is connected, we obtain \(K \subseteq C \setminus D\) or \(K \subseteq D \setminus C\). Therefore either \((A \cup D, B \cap C)\) or \((A \cup C, B \cap D)\) is in \(P\) by consistency to \((V(G) \backslash K, K \cup N(K))\), and not in \(Q\) by consistency to \((B, A)\).

Hence there is a corner separation of \((A, B)\) and \((C, D)\) distinguishing \(P\) and \(Q\) efficiently. By Lemma 2.2 it is nested with every separation in \(N\) that is also nested with \((A, B)\), as well as with \((C, D)\). Hence it crosses strictly less separations of \((A, B)\) than \((C, D)\), contradicting the choice of \((A, B)\). Thus \((A, B)\) is nested with \(N\).

**Case 2:** \(k \geq \ell\). We prove this case by induction on \(k\) with Case 1 as the base case. By the efficiency of \((A, B)\), the separation \((C, D)\) does not distinguish \(P\) and \(Q\). Thus we may assume that \((C, D)\) is in both \(P\) and \(Q\). If one of the corner separations \((A \cap D, B \cup C)\) or \((B \cap D, A \cup C)\) had order at most \(k\), then it would violate the maximality of \((A, B)\) by Lemma 2.2.

Indeed, it would be nested with every separation in \(N\) that is also nested with \((A, B)\), as well as with \((C, D)\). Hence it crosses strictly less separations of \((A, B)\) than \((C, D)\), contradicting the choice of \((A, B)\). Thus \((A, B)\) is nested with \(N\).

Hence we may assume that both these corner separations have order larger than \(k\) and therefore both links \(\ell_A\) and \(\ell_B\) are not empty. By Remark 2.3 the opposite corner separations \((A \cap C, B \cup D)\) and \((B \cap C, A \cup D)\) have order strictly less than \(|C \cap D|\) and are in \(P_{\ell+1}(b)\) since \(C \cap D \subseteq b\). As \(b\) is \(r\)-robust, \((C, D) \in P_{\ell+1}(b)\). Hence \((C, D)\) distinguishes \(P\) and \(P_{\ell+1}(b)\).

By the induction hypothesis, there is a separation \((E, F)\) of order at most \(\ell\) distinguishing \(P\) and \(P_{\ell+1}(b)\) efficiently that is nested with \(N\). We may assume that \((E, F) \in P_{\ell+1}(b)\) and \((F, E) \in P\). Furthermore, \((E, F)\) does not distinguish \(P\) and \(Q\), since \(|E \cap F| < |A \cap B|\). We claim that \((C, D) \leq (F, E)\). Indeed, since \((C, D)\) and \((F, E)\) are nested and \(P\) contains both of them, either \((C, D) \leq (F, E)\) or \((F, E) \leq (C, D)\). By consistency of \(P_{\ell+1}(b)\), we can conclude that \((C, D) \leq (F, E)\).

If the order of \((E \cap B, F \cup A)\) is at most \(k\), then it would distinguish \(P\) and \(Q\) efficiently. It would violate the maximality of \((A, B)\) by Lemma 2.2 since it is nested with every separation in \(N\) that is also nested with \((A, B)\), as well as with \((C, D)\) itself as \((C, D) \geq (E, F) \geq (E \cap B, F \cup A)\). Thus we may assume that \((E \cap B, F \cup A)\) has order larger than \(k\). Similarly we may assume that \((E \cap A, F \cup B)\) has order larger than \(k\).
Again by Remark 2.3, the opposite corner separations \((F \cap A, E \cup B)\) and \((F \cap B, E \cup A)\) have order less than \(|E \cap F|\). But by construction they separate \(\ell_A\) and \(\ell_B\) and hence \(b\), contradicting the fact that \(b\) is \((\leq \ell)\)-inseparable. □

**Theorem 4.8.** Let \(G\) be a finite graph, \(r \in \mathbb{N}\) and let \(\mathcal{P}\) be a canonical set of \(r\)-robust distinguishable \(\ell\)-profiles for some values \(\ell \leq r + 1\).

Then \(G\) has a canonical tree-decomposition \(T\) that distinguishes efficiently every two distinct profiles in \(\mathcal{P}\), and which has the further property that every separable block whose induced profile is in \(\mathcal{P}\) is equal to the unique part of \(T\) in which it is contained.

**Proof.** Let \(B\) be the set of blocks whose induced profiles are in \(\mathcal{P}\). We consider \(S(B)\) as above. Lemma 4.6 and Construction 3.9 yield a canonical tree-decomposition \(T(S(B))\) where by Lemma 4.3 and Theorem 3.10(i) every separable \(b \in B\) is equal to the unique part in which it is contained.

Let \(N\) be the nested separation system induced by \(T(S(B))\). With Lemma 4.7 we can apply Construction 3.15 to obtain \(N\), which by Theorem 3.16(ii) distinguishes the profiles in \(\mathcal{P}\) efficiently.

It is left to show that no separation \((A, B) \in \mathcal{N} \setminus \mathcal{N}\) separates a separable \(k\)-block \(b \in B\). Suppose for a contradiction that \((A, B) \in \mathcal{N} \setminus \mathcal{N}\) separates \(b\). Let \(P_t\) be the part of \(T(S(B))\) with \(P_t = b\). Note that since the adhesion sets \(P_t \cap P_u\) for any edge \(tu\) have size strictly smaller than \(k\) and since the only profile in \(\mathcal{P}\) inhabiting \(P_t\) is \(P_k(b)\), no profile in \(\mathcal{P}\) induces an \(\ell\)-profile for some \(\ell \geq k + 1\) on the torso \(H_t\). Then by Construction 3.15 and Lemma 3.6(iii) the induced separation \((A \cap P_t, B \cap P_t)\) is a proper separation of \(H_t\) distinguishing two \((\leq k)\)-profiles of \(H_t\) efficiently. But since \(H_t\) has no proper \((< k)\)-separation, it has no two distinguishable \((\leq k)\)-profiles.

Hence Theorem 2.4 yields a tree-decomposition \(T(N)\) with the desired properties. □

**Corollary 4.9.** Every finite graph \(G\) has a canonical tree-decomposition \(T\) that distinguishes efficiently every two distinct maximal robust profiles, and which has the further property that every separable block inducing a maximal robust profile is equal to the unique part of \(T\) in which it is contained.

**Proof.** Since the set of maximal robust profiles is by definition distinguishable, we can apply Theorem 4.8. □

**Corollary 4.10.** Every finite graph \(G\) has a canonical tree-decomposition \(T\) of adhesion less than \(k\) that distinguishes efficiently every two distinct \(k\)-profiles, and which has the further property that every separable \(k\)-block is equal to the unique part of \(T\) in which it is contained.

**Proof.** By Remark 2.5(i) any \(k\)-profile is \((k - 1)\)-robust. Since the set of all \(k\)-profiles is by definition distinguishable, we can apply Theorem 4.8. □

Theorem 4.8 fails if we do not require that \(\mathcal{P}\) is distinguishable:
Example 4.11. Consider the graph obtained by two cliques $K_1$ and $K_2$ of size at least $k+1 \geq 7$ sharing $k-1$ vertices, together with a vertex $v$ joined to two vertices of $K_1 - K_2$ and to two vertices of $K_2 - K_1$, see Figure 3.

Then $K_1 \cup K_2$ is a separable 5-block, as witnessed by the separation $(\{v\} \cup N(v), K_1 \cup K_2)$. But the two $(k+1)$-blocks $K_1$ and $K_2$ are only distinguished efficiently by $(K_1 \cup \{v\}, K_2 \cup \{v\})$. Since this separation crosses any separation separating $v$ from $K_1 \cup K_2$, there is no tree-decomposition that distinguishes $K_1$ and $K_2$ efficiently such that there is a part equal to $K_1 \cup K_2$. Moreover, even the union of the parts inhabited by $P_5(K_1 \cup K_2)$ in any tree-decomposition that distinguishes $K_1$ and $K_2$ efficiently contains with $v$ a vertex outside the block.
