An anion recognition receptor, a kind of thiourea derivative, was designed and synthesized by combining indoline-2,3-dione and 1,3-diaminothiourea. The anion recognition can be easily monitored by anion complexation induced changes in UV-vis absorption spectra. In particular, the binding ratio between the receptor and fluoride is 1:2 but in the case of dihydrogenphosphate and acetate are 1:1. Moreover, the affinity constants revealed that the receptor can recognize acetate well. Finally, $^1$H NMR experiments were carried out to explore the nature of interaction between this new receptor and acetate.

**Keywords:** thiourea; anion receptor; optical recognition; acetate

*Introduction*

Anions play significant roles in life processes and in the environment, such that the development of new anion receptors is of great interest and significance in host-guest chemistry. Anion artificial receptor has represented an unique application prospect in anion sensor, membrane transmit carrier and simulation, enzyme catalyst synthesis, etc. Also their effects as environmental pollutants have only recently been realized and several types of synthetic chemosensors have been developed to date. For the molecular design of the chemosensors, how to achieve the specific recognition of a certain anion and how to convert the recognition event into a signal are the key points.

Among the various important anionic analytes, biologically important acetate anion is one of the most significant due to its specific biochemical functions in the enzymes and antibodies. Acetate has unique chemical properties and can form the strongest hydrogen-bond interaction with hydrogen-bond donors because of the trigonal geometry and the high basicity. Many examples are available on selective receptor molecules for acetate anion. However, there is paucity of reports that describe the change in color in the visible region of the spectrum, and thereby allowing the visual detection of the acetate anion using a receptor. Accordingly, we designed and synthesized the new receptor 1 (Scheme 1) containing indoline-2,3-dione and 1,3-diaminothiourea subunits. UV-Vis spectral and $^1$H NMR titration experiments were employed to investigate the interaction between receptor 1 and several anions.

**Experiments**

**Reagents**

Unless otherwise specified, all reagents used in the synthesis were obtained commercially and were used without further purification. All anions used in the titration experiments were added in the form of tetra-$n$-butylammonium (TBA) salts, which were purchased...
from Sigma-Aldrich Chemical Co., stored under vacuum in a dessicator containing self-indicating silica-gel and fully dried before use. DMSO (dimethyl sulfoxide) was dried over CaH₂ and then distilled at reduced pressure.

**Apparatus**

¹H NMR spectra were obtained in a Varian UNITY Plus-400 MHz Spectrometer using tetramethylsilane (TMS) as an internal reference. SI-MS experiments were performed in a MARINER apparatus. C, H, N elemental analyses were carried out in an Elementar Vario EL. UV-vis spectra were recorded in a Shimadzu UV-2450 Spectrophotometer using a quartz cuvette (path length = 1 cm).

**General method**

All experiments were carried out at 298 K, unless otherwise mentioned. A 2.0 × 10⁻⁴ mol L⁻¹ solution of the compound 1 in DMSO was prepared and stored in dry atmosphere. This freshly prepared stock solution was used in all spectroscopic studies after appropriate dilution. 1.0 × 10⁻¹ mol L⁻¹ solutions of tetra-n-butylammonium (TBA) salts of the respective anions were prepared using dried and distilled DMSO and were appropriately stored in dry atmosphere.

¹H NMR titration experiments were carried out in DMSO-d₆ solution (TMS as internal reference). Receptor 1 (0.91 mg) was dissolved in DMSO-d₆ to obtain a 5 × 10⁻⁴ mol L⁻¹ solution. Then, increasing amounts of acetate anion (in DMSO-d₆) were added into that solution, and the host-guest interaction was monitored by ¹H NMR spectroscopy.

**Synthesis of N, N'-di-(indolino-2-one-3-yl)-1,3-diiminothiourea (I)¹¹**

A solution of indoline-2,3-dione (isatin) (588 mg, 4 mmol) in ethanol (20 mL) was added dropwise to a hot solution of 1,3-diaminothiourea (212 mg, 2 mmol) in ethanol/water (20 mL, v/v = 1/1) with stirring at reflux. After being stirred for 5 h, the solvent was removed in a flash evaporator. Recrystallization from ethanol yielded 664 mg of yellow crystals (83%). ¹H NMR (400 MHz, DMSO-d₆, Me₂Si): 14.95 (s, 2H, N–H), 7.58 (d, 2H, Ar-H, J 7.8 Hz), 7.43 (d, 2H, Ar-H, J 7.6 Hz), 7.25 (d, 2H, Ar-H, J 7.6 Hz), 6.97 (d, 2H, Ar-H, J 8.2 Hz). Elemental analysis: Calc. for C₁₂H₁₂N₂O₂S: C, 56.04; H, 3.32; N, 23.06; Found: C, 56.25; H, 3.37; N, 23.23. ESI-MS (m/z): 400.10 (M+H, calcd. 400).

**Results and Discussion**

**UV-vis spectroscopic measurement**

Firstly, to evaluate the binding ability, UV-vis titration experiments were carried out using a solution of the receptor 1 in dry DMSO tetrabutylammonium salts of AcO⁻, F⁻, H₂PO₄⁻, Cl⁻, Br⁻ and I⁻, at 298.2 ± 0.1K. The set of UV-vis spectra of 1 (1.0 × 10⁻⁴ mol L⁻¹) recorded upon the addition of increasing concentration of AcO⁻ is shown in Figure 1a. Two bands, one at 380 and another at 490 nm can be easily identified in the spectrum of the pure solution of 1. Upon addition of AcO⁻, there is an decrease of the 380 nm band intensity, while the lower energy band intensity increased gradually as a function of acetate concentration, generating an isosbestic point at 404 nm. As a consequence, the color of the solution changed from yellow to red, which could provide a convenient method for naked-eye detection of AcO⁻ as it was coordinated to 1 and the negative charge was dispersed to the π-conjugated system through intramolecular charge transfer (ICT) effect. A similar spectral change was observed upon the addition of H₂PO₄⁻ but the change was smaller. However, as Cl⁻, Br⁻ and I⁻ were titrated into 1, the spectra hardly changed even after an excess of the anions were added. In the case of F⁻, spectra changed without clear isosbestic points (see Figure 1b) implying formation of higher order complexes such as 1/F² = 1/2,¹² in analogy to the formation of [HF₄]⁻ species.¹³⁻¹⁴ This should be the result of the too small size of F⁻ anion.

Continuous variation method was used to determine the stoichiometric ratios of the receptors to the anion guests. In Figure 2 Job plot⁵,⁶ of receptor 1 and AcO⁻ in DMSO shows the maximum at a mole fraction of 0.5. This result indicates that the receptor 1 binds AcO⁻ guest with a 1:1 ratio. Moreover, similar results can also be obtained for H₂PO₄⁻. On the other hand, the Job plot reveals that 1 coordinated F⁻ with a 1:2 ratio, showing the maximum at a molar fraction of 0.67.

![Scheme 1](image-url)
For a complex of 1:1 stoichiometry, the relation in Equation (1) could be derived easily, where X is the absorption intensity, and $C_H$ or $C_G$ is the concentration of the host or the anion guest correspondingly.

$$X = X_0 + \left( X_{\text{lim}} - X_0 \right) \frac{C_H + C_G + 1/K_{\text{ass}} \cdot \left(C_H + C_G + 1/K_{\text{ass}}\right)^2}{4C_HC_G^{1/2}/2C_H}$$

For a complex of 1:2 stoichiometry, the relation in Equation (2) could be derived easily, where X is the absorption intensity, and $C_H$ or $C_G$ is the concentration of the host or the anion guest correspondingly.

$$\frac{X + X}{X_{\text{lim}} - X_0} = \left( C_{\text{ass}} \right)^3$$

The affinity constants of receptor 1 for anionic species were calculated and listed in Table 1 below.

Cl\(^-\), Br\(^-\) and I\(^-\) anions, were added to the solution of 1 (1.0 \times 10^{-5} \text{ mol L}^{-1}) respectively. The UV-vis spectra were recorded and the results presented that 1 could recognize AcO\(^-\) well (Figure 3).

Further supporting for the notion that hydrogen bond formed between 1 and anions came from \(^1\)H NMR spectroscopic analyses. They were carried out in DMSO-d\(_6\) under normal conditions of so-called NMR titration where the spectra of the receptor 1 were recorded in the presence of increasing concentrations of anions (Figure 4). Upon the addition of AcO\(^-\) to the solution of 1, the original peak of H\(_a\) (marked in Scheme 1) at 14.95 ppm disappeared, but that at 11.34 ppm assigned to H\(_b\) (marked in Scheme 1) shifted downfield. When 1.5 equivalents of AcO\(^-\) were added to 1, the peaks corresponding to H\(_b\) broadened and moved downfield to 12.64 ppm (\(\Delta\delta = 1.30 \text{ ppm}\)), which suggests that AcO\(^-\) was being combined with the two H\(_b\) of receptor 1 by hydrogen bonding. However, on the one hand, as to the signals of H\(_a\), they were still not observed in the whole titration process of AcO\(^-\) anions. On the other hand, the signals of the phenyl group shifted upfield, which indicated the increase of the electron density on the phenyl ring owing to the deprotonation taking place. As a function of the titration experiments and spectra analysis, the proposed binding mode of receptor 1 and AcO\(^-\) is given in Scheme 2.\(^{12}\)

**Conclusion**

In conclusion, 1 has been developed as a novel colorimetric receptor for AcO\(^-\) anion. It has been demonstrated that the receptor can bind anions in a 1:1 stoichiometry (except for F\(^-\)) with obvious colorimetric changes, where the complex had been formed between 1 and AcO\(^-\) by hydrogen bonding as proved by \(^1\)H NMR titration.
