Abstract

We give an effective version of a result reported by Serre asserting that the images of the Galois representations attached to an abelian surface with End(A) = \( \mathbb{Z} \) are as large as possible for almost every prime. Our algorithm depends on the truth of Serre’s conjecture for two dimensional odd irreducible Galois representations. Assuming this conjecture we determine the finite set of primes with exceptional image. We also give infinite sets of primes for which we can prove (unconditionally) that the images of the corresponding Galois representations are large. We apply the results to a few examples of abelian surfaces.

Mathematics Subject Classification: 11F80, 11G10
1 Introduction

Let $A$ be an abelian surface defined over $\mathbb{Q}$ with $\operatorname{End}(A) := \operatorname{End}_{\mathbb{Q}}(A) = \mathbb{Z}$. Let $\rho_\ell : G_\mathbb{Q} \to \operatorname{GSp}(4, \mathbb{Z}_\ell)$ be the compatible family of Galois representations given by the Galois action on $T_\ell(A) = A[\ell^\infty](\overline{\mathbb{Q}})$, the Tate modules of the abelian surface (we are assuming that $A$ is principally polarized). Each $\rho_\ell$ is unramified outside $\ell N$, where $N$ is the product of the primes of bad reduction of $A$. If we call $G_{\ell^\infty}$ the image of $\rho_\ell$ then we have the following result of Serre (cf. [Se 86]):

**Theorem 1.1** If $A$ is an abelian surface over $\mathbb{Q}$ with $\operatorname{End}(A) = \mathbb{Z}$ and principally polarized, then $G_{\ell^\infty} = \operatorname{GSp}(4, \mathbb{Z}_\ell)$ for almost every $\ell$.

Remark: If $G_\ell$ is the image of $\overline{\rho}_\ell$, the Galois representation on $\ell$-division points of $A(\overline{\mathbb{Q}})$ (and the residual mod $\ell$ representation corresponding to $\rho_\ell$), it is enough to show that $G_\ell = \operatorname{GSp}(4, \mathbb{F}_\ell)$ for almost every $\ell$ (cf. [Se 86]).

Serre proposed the problem of giving an effective version of this result: “...partir de courbes de genre 2 explicites, et tcher de dire partir de quand le groupe de Galois correspondant $G_\ell$ devient gal $\operatorname{GSp}(4, \mathbb{F}_\ell)$ ”. But Serre’s proof depends on certain ineffective results of Faltings and therefore does not solve this problem.

In this article, we will give an algorithm that computes a finite set $\mathcal{F}$ of primes containing all those primes (if any) with image of the corresponding Galois representation exceptional, i.e., different from $\operatorname{GSp}(4, \mathbb{F}_\ell)$. The validity of our method depends on the truth of Serre’s conjecture for 2-dimensional irreducible odd Galois representations, conjecture (3.2.4) in [Se 87]. This means that if $\ell$ is a prime such that $G_\ell \neq \operatorname{GSp}(4, \mathbb{F}_\ell)$ and $\ell \notin \mathcal{F}$, then $G_\ell$ has a 2-dimensional irreducible (odd) component that violates Serre’s conjecture.

The method is inspired by the articles [Se 72], [Ri 75], [Ri 85] and [Ri 97] where the case of 2-dimensional Galois representations is treated.

In the examples, we also give infinite sets of primes for which we can prove the result on the images unconditionally, i.e., without assuming Serre’s conjecture. Results of this kind were previously obtained by Le Duff only under the extra assumption of semiabelian reduction of the abelian surface at some prime. Our technique has two advantages: it does not have any restriction on the reduction type of the abelian surface, and in the case of semiabelian
reduction it allows us to prove the result on the images (unconditionally) for larger sets of primes.
I want to thank N. Vila, A. Brumer and J-P. Serre for useful remarks and comments.

2 Main Tools

2.1 Maximal subgroups of $\text{PGSp}(4, \mathbb{F}_\ell)$

In [Mi 14], Mitchell gives the following classification of maximal proper subgroups $G$ of $\text{PSp}(4, \mathbb{F}_\ell)$ ($\ell$ odd), as groups of transformations of the projective space having an invariant linear complex:

1) a group having an invariant point and plane
2) a group having an invariant parabolic congruence
3) a group having an invariant hyperbolic congruence
4) a group having an invariant elliptic congruence
5) a group having an invariant quadric
6) a group having an invariant twisted cubic
7) a group $G$ containing a normal elementary abelian subgroup $E$ of order 16, with: $G/E \cong A_5$ or $S_5$
8) a group $G$ isomorphic to $A_6, S_6$ or $A_7$.

For the relevant definitions see [Hi 85], see also [Bl 17] and [Os 77] for cases 7) and 8).

Remark: This classification is part of a general “philosophy”: the subgroups of $\text{GL}(n, \mathbb{F}_\ell), \ell$ large, are essentially subgroups of Lie type, with some exceptions independent of $\ell$ (see [Se 86]).

From this we obtain a classification of maximal proper subgroups $H$ of $\text{PGSp}(4, \mathbb{F}_\ell)$ with exhaustive determinant. It is similar to the above one, except that cases 7) and 8) change according to the relation between $H$ and $G$, given by the exact sequence:

$$1 \rightarrow G \rightarrow H \rightarrow \{\pm 1\} \rightarrow 1.$$
2.2 The action of Inertia

From now on we will assume that \( \ell \) is a prime of good reduction for the abelian surface \( A \). Then it follows from results of Raynaud that the restriction \( \bar{\rho}_\ell|_{I_\ell} \) has the following property (cf. [Ra 74], [Se 72]):

**Theorem 2.1** If \( V \) is a Jordan-Hölder quotient of the \( I_\ell \)-module \( A[\ell](\Q) \) of dimension \( n \) over \( \F_\ell \), then \( V \) admits an \( \F_\ell \)-vector space structure of dimension 1 such that the action of \( I_\ell \) on \( V \) is given by a character \( \phi : I_{\ell,t} \rightarrow \F_\ell^* \) (\( t \) stands for tame) with:

\[
\phi = \phi_1^{d_1} \cdots \phi_n^{d_n}, \quad (2.1)
\]

where \( \phi_i \) are the fundamental characters of level \( n \) and \( d_i = 0 \) or 1, for every \( i = 1, 2, \ldots, n \).

All this statement is proved by Serre in [Se 72] except for the bound for the exponents, which is the result of Raynaud mentioned above, later generalized by Fontaine-Messing.

We will use the following lemmas repeatedly (cf. [Di 1901]):

**Lemma 2.2** Let \( M \in \text{Sp}(4, F) \) be a symplectic transformation over a field \( F \). The roots of the characteristic polynomial of \( M \) can be written as \( \alpha, \beta, \alpha^{-1}, \beta^{-1} \), for some \( \alpha, \beta \).

Remark: A similar result holds in general for the groups \( \text{Sp}(2n, F) \).

In the case of the Galois representations attached to \( A \), we know that \( \det(\bar{\rho}_\ell) = \chi^2 \), where \( \chi \) is the mod \( \ell \) cyclotomic character. Therefore, we obtain:

**Lemma 2.3** The roots of the characteristic polynomial of \( \bar{\rho}_\ell(\text{Frob } p) \in G_\ell \) can be written as \( \alpha, \beta, p/\alpha, p/\beta \) (\( p \nmid \ell N \)).

Remark: Here \( \text{Frob } p \) denotes the (arithmetic) Frobenius element, defined up to conjugation. The value of the representation in it is well defined precisely because of the fact that the representation is unramified at \( p \).

Proof: Use lemma [2.2] \( G_\ell \subseteq \text{GSp}(4, \F_\ell) \), and the exact sequence:

\[
1 \rightarrow \text{Sp}(4, \F_\ell) \rightarrow \text{GSp}(4, \F_\ell) \rightarrow \F_\ell^* \rightarrow 1.
\]
Remark: The same is true for $\rho_\ell (\text{Frob } p) \in G_{\ell \infty}$. Thus, the characteristic polynomial of $\rho_\ell (\text{Frob } p)$ has the form:

$$x^4 - a_p x^3 + b_p x^2 - p a_p x + p^2$$

with $a_p, b_p \in \mathbb{Z}, a_p = \text{trace}(\rho_\ell (\text{Frob } p))$.

From formula (2.1), we obtain the following possibilities for $\bar{\rho}_\ell |_{I_\ell}$ ($\ell \nmid N$):

- \[
\begin{pmatrix}
1 & * & * & * \\
0 & \chi & * & * \\
0 & 0 & 1 & * \\
0 & 0 & 0 & \chi
\end{pmatrix};
\begin{pmatrix}
\psi_2 & 0 & * & * \\
0 & \psi_2^\ell & * & * \\
0 & 0 & \psi_2 & 0 \\
0 & 0 & 0 & \psi_2^\ell
\end{pmatrix};
\begin{pmatrix}
\psi_2 & 0 & * & * \\
0 & \psi_2^\ell & * & * \\
0 & 0 & 1 & * \\
0 & 0 & 0 & \chi
\end{pmatrix};
\begin{pmatrix}
\psi_2 & 0 & * & * \\
0 & \psi_2^\ell & * & * \\
0 & 0 & 1 & * \\
0 & 0 & 0 & \chi
\end{pmatrix}
\]

where $\psi_i$ is a fundamental character of level $i$.

3 Study of the Images

3.1 Reducible case: 1-dimensional constituent

Let $c$ be the conductor of the compatible family $\{\rho_\ell\}$. For the case of the jacobian of a genus 2 curve, it can be computed using an algorithm of Q. Liu except for the exponent of 2 in $c$, which can easily be bounded using the discriminant of an integral model of the curve (see [Liu 94]).

Suppose that the representation $\bar{\rho}_\ell$ is reducible with a 1-dimensional sub(or quotient) representation given by a character $\mu$. This character is unramified outside $\ell N$ and takes values in $\bar{F}_\ell$, therefore from the description of $\bar{\rho}_\ell |_{I_\ell}$ given in section 2.2 we have $\mu = \varepsilon \chi^i$, with $\varepsilon$ unramified outside $N$ and $i = 0$ or 1. Clearly $\text{cond}(\varepsilon) | c$. After semi-simplification, we have:

$$\bar{\rho}_\ell \cong \varepsilon \chi^i \oplus \pi,$$
for a 3-dimensional representation $\pi$ with $\det(\pi) = \varepsilon^{-1} \chi^{2-i}$.

Therefore, $\text{cond}(\varepsilon^2) \mid c$. Let $d$ be the maximal integer such that $d^2 \mid c$. If we take a prime $p \equiv 1 \pmod{d}$, we have $\varepsilon(p) = 1$ so $\chi^i$ is a root of the characteristic polynomial of $\bar{\rho}_\ell(Frob p)$. This gives:

$$b_p - a_p(p + 1) + p^2 + 1 \equiv 0 \pmod{\ell}, \quad (3.1)$$

both for $i = 0$ and $i = 1$ (in agreement with lemma 2.3).

By the Riemann hypothesis, the roots of the characteristic polynomial of $\rho_\ell(Frob p)$ have absolute value $\sqrt{p}$. This gives automatically bounds for the absolute values of the coefficients $a_p$ and $b_p$, and from these bounds we see that for large enough $p$ congruence (3.1) is not an equality. Therefore, only finitely many primes $\ell$ may verify (3.1).

Variant: Instead of taking a prime $p \equiv 1 \pmod{d}$, we can work in general with $p$ of order $f$ in $(\mathbb{Z}/d\mathbb{Z})^*$. Let $Pol_p(x)$ be the characteristic polynomial of $\bar{\rho}_\ell(Frob p)$. Then $\varepsilon(p)p^i$ is a root of $Pol_p(x)$, with $i = 0$ or $1$, and $\varepsilon(p)^f = 1 \in \mathbb{F}_\ell$. Then

$$\text{Res}(Pol_p(x), x^f - 1) \equiv 0 \pmod{\ell} \quad (3.2)$$

where $\text{Res}$ stands for resultant (again, cases $i = 0$ and $1$ agree).

This variant is used in the examples to avoid computing $Pol_p(x)$ for large $p$.

### 3.2 Reducible case: “related” 2-dimensional constituents

Suppose that, after semi-simplification, $\bar{\rho}_\ell$ decomposes as the sum of two 2-dimensional irreducible Galois representations: $\bar{\rho}_\ell \cong \pi_1 \oplus \pi_2$. Assume also that these two constituents are related by lemma 2.3, i.e., if $\alpha, \beta$ are the roots of the characteristic polynomial of $\pi_1(Frob p)$, then $p/\alpha, p/\beta$ are the roots of that of $\pi_2(Frob p)$. If not, then it follows from lemma 2.3 that $\alpha = p/\beta$, so $\det(\pi_1) = \det(\pi_2) = \chi$; this case will be studied in the next subsection.

Using the description of $\bar{\rho}_\ell|_{I_\ell}$ given in section 2.2 we see that one of the following must happen (where $\varepsilon$ is a character unramified outside $N$):

- **Case 1:** $\det(\pi_1) = \varepsilon \chi^2$, $\det(\pi_2) = \varepsilon^{-1}$.
- **Case 2:** $\det(\pi_1) = \varepsilon \chi$, $\det(\pi_2) = \varepsilon^{-1} \chi$.  

7
• Case 1: In this case we have the factorization:

\[ \text{Pol}_p(x) \equiv (x^2 - rx + p^2 \varepsilon(p)) (x^2 - \frac{rx}{p \varepsilon(p)} + \varepsilon^{-1}(p)) \pmod{\ell}. \]

As in the previous subsection: \( \text{cond} (\varepsilon) | d \). Eliminating \( r \) from the equation, we obtain:

\[ Q_p(b_p, a_p, \varepsilon(p)) := (\varepsilon(p)b_p - 1 - p^2 \varepsilon(p)^2)(p \varepsilon(p) + 1)^2 - a_p^2 p \varepsilon(p)^2 \equiv 0 \pmod{\ell}. \]

If we take \( p \equiv 1 \pmod{d} \), we obtain:

\[ (b_p - 1 - p^2)(p + 1)^2 \equiv a_p^2 p \pmod{\ell}. \quad (3.3) \]

Again, from the bounds for the coefficients we see that for large enough \( p \) this is not an equality. Thus, only finitely many \( \ell \) can satisfy (3.3).

Alternatively, for computational purposes, we may take \( p \) with \( p^f \equiv 1 \pmod{d} \). Then we have:

\[ \text{Res}(Q_p(b_p, a_p, x), x^f - 1) \equiv 0 \pmod{\ell}. \quad (3.4) \]

• Case 2: This case is quite similar to the previous one. We start with:

\[ \text{Pol}_p(x) \equiv (x^2 - rx + p \varepsilon(p)) (x^2 - \frac{rx}{\varepsilon(p)} + p \varepsilon^{-1}(p)) \pmod{\ell} \]

with \( \text{cond}(\varepsilon) | d \). From this:

\[ Q'_p(b_p, a_p, \varepsilon(p)) := (\varepsilon(p)b_p - p - p \varepsilon(p)^2)(\varepsilon(p) + 1)^2 - a_p^2 \varepsilon(p)^2 \equiv 0 \pmod{\ell}. \]

Thus, if \( p \equiv 1 \pmod{d} \),

\[ 4(b_p - 2p) \equiv a_p^2 \pmod{\ell}. \quad (3.5) \]

In general, if \( p^f \equiv 1 \pmod{d} \),

\[ \text{Res}(Q'_p(b_p, a_p, x), x^f - 1) \equiv 0 \pmod{\ell}. \quad (3.6) \]

In this case, the fact that this holds only for finitely many primes \( \ell \) is non-trivial. It may be thought of as a consequence of theorem [1.1].
3.3 The remaining reducible case

As explained above, in the remaining reducible case we have: $\bar{\rho}_s \cong \pi_1 \oplus \pi_2$ with $\det(\pi_1) = \det(\pi_2) = \chi$. We have described in section 2.2 the possibilities for $\bar{\rho}_l|_{I_\ell}$. This gives for $\pi_1|_{I_\ell}$ and $\pi_2|_{I_\ell}$:

$$\begin{pmatrix} 1 & * \\ 0 & \chi \end{pmatrix} \quad \text{or} \quad \begin{pmatrix} \psi_2 & 0 \\ 0 & \psi_2^\ell \end{pmatrix}.$$  

Besides, $\operatorname{cond}(\pi_1)\operatorname{cond}(\pi_2) | c$.

At this point we invoke Serre’s conjecture (3.2.4) (see [Se 87]) that gives us a control on $\pi_1$ and $\pi_2$. Both representations should be modular of weight 2, i.e., there exist two cusp forms $f_1, f_2$ with:

$$\bar{\rho}_{f_1, \ell} \cong \pi_1, \quad \bar{\rho}_{f_2, \ell} \cong \pi_2, \quad f_1 \in S_2(N_1), \quad f_2 \in S_2(N_2),$$

$N_1N_2 | c$ (we are assuming $\pi_1, \pi_2$ to be irreducible; otherwise, they are covered by section 3.1). Both cusp forms have trivial nebentypus.

There are finitely many cusp forms in these finitely many spaces. So we have an algorithm to detect the primes $\ell$ falling in this case by comparing characteristic polynomials mod $\ell$, due to

$$\bar{\rho}_{f_1, \ell} \cong \bar{\rho}_{f_2, \ell} \oplus \bar{\rho}_{f_2, \ell}.$$  

We take all pairs of integers $N_1, N_2$ with $N_1N_2 = c$ and all pairs of cusp forms $f_1 \in S_2(N_1), \ f_2 \in S_2(N_2)$ (either newforms or oldforms). If we denote by $Pol_{f_i, p}(x)$ the characteristic polynomial of $\rho_{f_i, \ell}(\text{Frob } p)$ ($i = 1, 2$), we should have for some such pair $f_1, f_2$:

$$Pol_{f_1, p}(x)Pol_{f_2, p}(x) \equiv Pol_p(x) \pmod{\ell} \quad (3.7)$$

for every $p \nmid \ell N$.

Theorem [1.1] guarantees that this can only happen for finitely many primes.

Remark: The Galois representations $\rho_{f_i, \ell}$ attached to $f_i$ were constructed by Deligne (cf. [De 71]). The polynomials $Pol_{f_i, p}(x)$ are of the form

$$Pol_{f_i, p}(x) = x^2 - c_p x + p,$$

where $c_p$ is the eigenvalue of $f_i$ corresponding to the Hecke operator $T_p$. These eigenvalues, and a fortiori the characteristic polynomials $Pol_{f_i, p}(x)$ for
any cusp form $f$, can be computed with an algorithm of W. Stein (cf. [St]). The compatible family of Galois representations constructed by Deligne, in the case of a cusp form $f \in S_2(N)$, shows up in the jacobian $J_0(N)$ of the modular curve $X_0(N)$: it agrees with a two-dimensional constituent of the one attached to the abelian variety $A_f$ corresponding to $f$.

For computational purposes, we introduce the following variant: observe that either $N_1$ or $N_2$ (say $N_1$) satisfy

$$N_1 \mid c, \ N_1 \leq \sqrt{c}.$$ 

Consider all divisors of $c$ verifying this, maximal (among divisors of $c$) with this property. Call $S$ the set of such divisors. Then we are supposing that there exists $f \in S_2(t)$ with $t \in S$ and

$$\text{Res}(Pol_{f,p}(x), Pol_p(x)) \equiv 0 \pmod{\ell},$$

for every $p \nmid \ell N$. Therefore, for some $t \in S$

$$\text{Res}(\prod_{f \in S_2(t)} Pol_{f,p}(x), Pol_p(x)) \equiv 0 \pmod{\ell}, \quad (3.8)$$

for every $p \nmid \ell N$.

With this formula we compute in any given example all primes $\ell$ falling in this case.

Remark: In all reducible cases (sections 3.1, 3.2 and 3.3) we have considered reducibility over $\overline{\mathbb{F}}_\ell$.

3.4 Stabilizer of a hyperbolic or elliptic congruence

If $G_\ell$ corresponds to an irreducible subgroup inside (its projective image) some of the maximal subgroups in cases 3) and 4) of Mitchell’s classification, there is a normal subgroup of index 2 of $G_\ell$ such that

$$1 \to M_\ell \to G_\ell \to \{\pm 1\} \to 1,$$

and the subgroup $M_\ell$ is reducible (not necessarily over $\mathbb{F}_\ell$).

In fact, a hyperbolic (elliptic) congruence is composed of all lines meeting
two given skew lines in the projective three dimensional space over $\mathbb{F}_\ell$ defined over $\mathbb{F}_\ell (\mathbb{F}_{\ell^2},$ respectively), called the axes of the congruence (see [Hi 85]). The stabilizer of such congruences consists of those transformations that fix or interchange the two axes, and it contains the normal reducible index two subgroup of those transformations that fix both axes.

From the description of $\bar{\rho}_\ell|_I$ given in section 2.2 we see that if $\ell > 3$, it is contained in $M_\ell$. Therefore, if we take the quotient $G_\ell/M_\ell$ we obtain a representation $G_\mathbb{Q} \to C_2$ whose kernel is a quadratic field unramified outside $N$. Then, there is a quadratic character $\phi : (\mathbb{Z}/c\mathbb{Z})^* \to C_2$ with:

\[
\phi(p) = -1 \Rightarrow \bar{\rho}_\ell(\text{Frob } p) \text{ is of the form: }
\begin{pmatrix}
0 & 0 & * & * \\
0 & 0 & * & * \\
* & * & 0 & 0 \\
* & * & 0 & 0
\end{pmatrix}.
\]

Therefore, trace($\bar{\rho}_\ell(\text{Frob } p)$) = 0 , i.e.,

\[
a_p \equiv 0 \pmod{\ell}, \quad (3.9)
\]

for every $p \nmid \ell N$ with $\phi(p) = -1$.

Considering all quadratic characters ramifying only at the primes in $N$ we detect the primes $\ell$ falling in this case.

Once again, from theorem 1.1, it follows that this set is finite (of course, this fact strongly depends on the assumption $\text{End}(A) = \mathbb{Z}$).

### 3.5 Stabilizer of a quadric

This case can be treated exactly as the one above: assuming again absolute irreducibility of the image $G_\ell$, it contains a normal subgroup of index 2, and we obtain a quadratic character unramified outside $N$ verifying formula (3.9). In fact, in this case $\bar{\rho}_\ell$ is the tensor product of two irreducible 2-dimensional Galois representations (see [Hi 85], page 28), one of them dihedral (this is the necessary and sufficient condition for the tensor product to be symplectic, see [B-R 89], page 51), so the matrices in $G_\ell$ are of the form:

\[
\begin{pmatrix}
av & 0 & cv & 0 \\
0 & az & 0 & cz \\
bv & 0 & dv & 0 \\
0 & bz & 0 & dz
\end{pmatrix} \text{ or } \begin{pmatrix}
0 & az & 0 & cz \\
av & 0 & cv & 0 \\
0 & bz & 0 & dz \\
bv & 0 & dv & 0
\end{pmatrix},
\]

depending on the value of the quadratic character $\phi$.  

3.6 Stabilizer of a twisted cubic

This case is incompatible with the description of $\bar{\rho}_I^\ell$ given in section 2.2. In fact, in this case all upper-triangular matrices are of the form (see [Hi 85], page 233):

$$
\begin{pmatrix}
  a^3 & * & * & * \\
  0 & a^2d & * & * \\
  0 & 0 & ad^2 & * \\
  0 & 0 & 0 & d^3
\end{pmatrix}.
$$

In no case is the subgroup of $G_\ell$ given by $\bar{\rho}_I^\ell$ of this form.

3.7 Exceptional cases

The cases already studied cover all possibilities in the classification except the exceptional groups, i.e., cases 7) and 8).

In these cases, comparing the exceptional group $H \subseteq \text{PGSp}(4, \mathbb{F}_\ell)$ (its order and structure) with the fact that $\mathbb{P}(G_\ell)$ contains the image of $\mathbb{P}(\bar{\rho}_I^\ell)$ described in section 2.2, we end up with the only possibilities ($\ell > 3$):

$$
\ell = 5, 7.
$$

For these two primes, as for any prime we suspect of satisfying $G_\ell \neq \text{GSp}(4, \mathbb{F}_\ell)$, we compute several characteristic polynomials $\text{Pol}_p(x) \mod \ell$. At the end, either we prove that it must be $G_\ell = \text{GSp}(4, \mathbb{F}_\ell)$ (because the orders of the roots of the computed polynomials do not give any other option) or we reinforce our suspicion that $\ell$ is exceptional.

3.8 Conclusion

Having gone through all cases in the classification (the stabilizer of a parabolic congruence is reducible, it has an invariant line of the complex, cf. [Mi 14]) we conclude that for all primes $\ell$ except those whose image, according to our algorithm, may fall in a proper subgroup (according to theorem [11], only finitely many) the image of $\mathbb{P}(\bar{\rho}_\ell)$ is $\text{PGSp}(4, \mathbb{F}_\ell)$.

From this it easily follows that if $\ell$ is not one of the finitely many exceptional primes we have $G_\ell = \text{GSp}(4, \mathbb{F}_\ell)$ and applying a lemma of [Se 86] (see also [Se 68]) we obtain $G_{\ell \infty} = \text{GSp}(4, \mathbb{Z}_\ell)$.

Recall that at one step we have assumed the veracity of Serre’s conjecture (3.2.4_\ell).
4 An example

We have applied the algorithm to the example given by the jacobian of the genus 2 curve given by the equation:

\[ y^2 = x^6 - x^3 - x + 1. \]

The algorithm of Q. Liu computes the prime-to-2 part of the conductor. From this computation and the bound of the conductor in terms of the discriminant of an integral equation (cf. [Liu 94]) we obtain: \( c | 2^{12} \cdot 23 \cdot 5 \).

We exclude a priori the primes dividing the conductor: 2, 5 and 23.

We sketch some of the computations performed:

- Reducible cases with 1-dimensional constituent or two related 2-dimensional constituents:
  The maximal possible value of the conductor of \( \varepsilon \) is \( d = 64 \). We compute the characteristic polynomials of \( \rho_\ell(\text{Frob}_p) \) for the primes \( p = 229, 257, 641, 769 \) and applying the algorithm (equations (3.2), (3.4) and (3.6)) we easily check that no prime \( \ell > 3 \) falls in these cases.
  Remark: The characteristic polynomials used at this and the remaining steps can be found in section 6.

- Remaining reducible case:
  First we describe the set of special divisors of \( c \):
  \( S = \{368, 460, 512, 640\} \).
  Then we compute, for each \( t \in S \) and each Hecke eigenform \( f \in S_2(t) \), the characteristic polynomial \( Pol_{f,p}(x) \) for \( p = 3, 7, 11, 13, 17, 19 \) with the algorithm implemented by W. Stein ([St]). Then, comparing these polynomials with the characteristic polynomials of \( \rho_\ell(\text{Frob}_p) \) as in formula (3.8) we see that no prime \( \ell > 3 \) falls in this case.

- Cases “governed” by a quadratic character:
  We have to consider all possible quadratic characters \( \phi \) unramified outside \( c \) (there are 15) and for each of them take a couple of primes \( p \) with \( \phi(p) = -1 \) and \( a_p \neq 0 \). Applying the algorithm (formula (3.9)) we see that no prime \( \ell > 3 \) falls in these cases. At this step we have used the values \( a_p \) for the primes \( p = 3, 7, 13, 97, 113, 569, 769 \).

- Exceptional cases:
  We compute the reduction of a few characteristic polynomials modulo 7 and we find elements whose order (in PGSp(4, \( \mathbb{F}_7 \))) does not correspond to the
structure of any of the exceptional groups.
From all the above computations we conclude:

**Theorem 4.1** Let $A$ be the jacobian of the genus 2 curve:

$$y^2 = x^6 - x^3 - x + 1.$$ 

Let $G_{\ell^{\infty}}$ be the image of $\rho_{A, \ell}$, the Galois representation on $A[\ell^{\infty}](\overline{\mathbb{Q}})$, whose conductor divides $2^{12} \cdot 5 \cdot 23$. Then, assuming Serre’s conjecture (3.2.4) it holds:

$$G_{\ell^{\infty}} = \text{GSp}(4, \mathbb{Z}_\ell)$$

for every $\ell > 5$, $\ell \neq 23$.

Remark: We are not claiming that the image is not maximal for any of the four excluded primes.

## 5 Unconditional Results and more examples

### 5.1 The case of semiabelian reduction

For certain genus 2 curves one can prove that the image is large for an infinite set of primes by using the following results of Le Duff [LeD 98]:

**Proposition 5.1** Let $A$ be an abelian surface defined over $\mathbb{Q}$. Suppose that for a prime $p$ of bad reduction of $A$, $\tilde{A}_p^0$ (the connected component of 0 in the special fiber of the Nron Model of $A$ at $p$) is an extension of an elliptic curve by a torus. Then, for every prime $\ell \neq p$ with $\ell \nmid \Phi(p)$ (number of connected components of $\tilde{A}_p$), $G_{\ell}$ contains a transvection.

Recall that a transvection is an element $u$ such that $\text{Image}(u - 1)$ has dimension 1.

**Proposition 5.2** ([LeD 98]) If $G \subset \text{Sp}(4, \mathbb{F}_\ell)$ is a proper maximal subgroup containing a transvection, all its elements have reducible (over $\mathbb{F}_\ell$) characteristic polynomial. Therefore, a transvection together with a matrix with irreducible characteristic polynomial generate $\text{Sp}(4, \mathbb{F}_\ell)$. 

14
Remark: We can also find in [Mi 14] the list of maximal subgroups of
$\text{PSp}(4, \mathbb{F}_\ell)$ containing central elations, and a central elation is the image in
$\text{PSp}(4, \mathbb{F}_\ell)$ of a transvection in $\text{Sp}(4, \mathbb{F}_\ell)$. These groups correspond to cases
1) and 3) in section 2.1 or to a group having an invariant line of the complex,
defined over $\mathbb{F}_\ell$.
Recall that $\text{Pol}_q(x)$ denotes the characteristic polynomial of $\rho_\ell(\text{Frob} q)$ for
any prime $q$ of good reduction for the abelian surface $A$ and $\ell \neq p$. From the
two previous results it follows:

**Theorem 5.3** (Le Duff) Let $p$ be a bad reduction prime verifying the condi-
tion of proposition 5.1 and $q$ a prime with $\text{Pol}_q(x)$ irreducible, then for every
$\ell \nmid 2pq\Phi(p)$ such that $\text{Pol}_q(x)$ is irreducible modulo $\ell$, $G_\ell = \text{GSp}(4, \mathbb{F}_\ell)$.
If $\Delta_q$ is the discriminant of $\text{Pol}_q(x)$ and $\Delta_{Q_q}$ the discriminant of $Q_q(x) := x^2 - a_qx + b_q - 2q$ the irreducibility condition reads:
$$(\Delta_q) = -1 \text{ and } (\frac{\Delta_{Q_q}}{\ell}) = -1.$$ 

**EXAMPLE** (Le Duff): Take the genus 2 curve:

$$C_2 : \quad y^2 = x^5 - x + 1.$$ 

$A_2 = J(C_2)$ has good reduction outside 2, 19, 151. For $p = 19, 151$ the condi-
tion in proposition 5.1 is satisfied with $\Phi(p) = 1$.
Take $q = 3$, $\text{Pol}_3(x)$ is irreducible and theorem 5.3 gives: $G_\ell = \text{GSp}(4, \mathbb{F}_\ell)$
for every $\ell > 3$ with $\left(\frac{61}{\ell}\right) = -1$ and $\left(\frac{2}{\ell}\right) = -1$.
Remark: Of course, considering more irreducible characteristic polynomi-
als one can obtain the same result for other primes. In particular, $G_\ell = \text{GSp}(4, \mathbb{F}_\ell)$ for $\ell = 19, 151$ (cf. [LeD 98]).
Remark: The example in the previous section also verifies Le Duff’s con-
dition.

Let us apply our method to this example. The invariants are:
$c = \text{cond}(A_2) | 2^8 \cdot 19 \cdot 151$ (computed with Liu’s algorithm), then $\text{cond}(\varepsilon) | d = 16$; and the set $S = \{256, 604, 608\}$.
In this example, we only have to worry about those maximal subgroups in
Mitchell’s classification containing central elations. Therefore, we only have
to discard the maximal subgroups considered in sections 3.1, 3.3 and 3.4.
The reducible case with 1-dimensional constituent is easily handled using the characteristic polynomials (see section 6) $Pol_p(x)$ for $p = 17, 97$ and we conclude that no prime $\ell > 2$ falls in this case.

Due to the fact that the spaces of modular forms $S_2(t)$ for $t \in S$ are rather large, we decided to save computations and to apply the procedure described in section 3.3, formula (3.8), only to the prime $p = 3$. After computing all resultants of $Pol_3(x)$ with all the characteristic polynomials $Pol_{f,3}(x)$ for $f \in S_2(t)$, $t \in S$, we find the possibly exceptional primes $\ell > 2$:

$$\ell = 3, 5, 11, 19, 29, 31, 41, 61, 109, 151.$$  

Having computed the characteristic polynomials

$$Pol_p(x) \quad \text{for} \quad p = 11, 41, 79, 101, 199, 211$$

(see section 6) we checked that for each of the ten possibly exceptional primes $\ell$ listed above one of these six polynomials is irreducible modulo $\ell$. Then, applying theorem 5.3, we conclude that none of these primes is exceptional. Thus, no $\ell > 2$ has reducible image.

Cases governed by a quadratic character: we have to consider all possible quadratic characters $\phi$ unramified outside $c$ and for each of them take a couple of primes $p$ with $\phi(p) = -1$ and $a_p \neq 0$. We use the values $a_p$ for $p = 3, 5, 97, 257$ (see section 6) and an application of the algorithm (formula (3.9)) proves that the only possibly exceptional primes $\ell > 2$ are:

$$\ell = 3, 5, 11, 97, 257.$$  

We already mentioned that 3, 5 and 11 are not exceptional. Applying theorem 5.3 again we see that 97 and 257 are also non-exceptional because $Pol_{11}(x)$ is irreducible modulo 97 and $Pol_{281}(x)$ is irreducible modulo 257. Then, we conclude:

**Theorem 5.4** Let $A_2$ be the jacobian of the genus 2 curve given by the equation $y^2 = x^5 - x + 1$. Assume Serre’s conjecture (3.2.4?) (cf. [Se 87]). Then the images of the Galois representations on the $\ell$-division points of $A_2$ are

$$G_\ell = \text{GSp}(4, \mathbb{F}_\ell), \quad \text{for every} \; \ell > 2.$$  

Remark: $\bar{\rho}_2$ is also irreducible over $\mathbb{F}_2$. This irreducibility for all $\ell$ is equivalent to the fact that $A_2$ is isolated in its isogeny class in the sense that any
abelian variety isogenous to $A_2$ over $\mathbb{Q}$ is isomorphic to $A_2$ over $\mathbb{Q}$. Unfortunately, this condition of being isolated is not effectively verifiable.

Among the subgroups containing central elations, we have used Serre’s conjecture only to eliminate the following one:

$$G_\ell \subseteq \{ A \times B \in \text{GL}(2, \mathbb{F}_\ell) \times \text{GL}(2, \mathbb{F}_\ell) : \det(A) = \det(B) = \chi \}. \quad (*)$$

Take $q$ with $Pol_q(x)$ irreducible. If $(\frac{\Delta_{q,\ell}}{\ell}) = -1$ case (*) cannot hold, because the matrices $A$ and $B$ would have their traces in $\mathbb{F}_{\ell^2} \setminus \mathbb{F}_\ell$. This follows from the factorization:

$$Pol_q(x) = \left( x^2 - \left( \frac{a_q + \sqrt{\Delta_{q,\ell}}}{2} \right) x + q \right) \left( x^2 - \left( \frac{a_q - \sqrt{\Delta_{q,\ell}}}{2} \right) x + q \right).$$

Then, again using $Pol_3(x)$ we prove without using Serre’s conjecture the following

**Theorem 5.5** The images of the Galois representations on the $\ell$-division points of $A_2$ are

$$G_\ell = \text{GSp}(4, \mathbb{F}_\ell), \text{ for every } \ell > 3 \text{ with } \left( \frac{5}{\ell} \right) = -1.$$ 

Observe that we have obtained an unconditional result that is stronger than the one in [LeD 98], because it only uses the condition on one of the discriminants (thus, it applies to more primes).

We warn the reader that there is a mistake in [LeD 98], pag. 521, the polynomial $Pol_{11}$ corresponding to this example is wrongly computed. It should read:

$$x^4 + 7x^3 + 31x^2 + 77x + 121.$$

**5.2 Unconditional results in the general case**

We will show now that even in the case that the condition of proposition 5.1 is not verified at any prime, we can obtain similar unconditional results.

In an arbitrary example, if we do not use Serre’s conjecture, there is another case to consider (in addition to case (*)):

$$G_\ell \subseteq \{ M \in \text{GL}(2, \mathbb{F}_{\ell^2}) : \det(M) = \chi \}. \quad (**$$
The inclusion of this group in $\text{GSp}(4, \mathbb{F}_\ell)$ is given by the map:
$M \rightarrow \text{diag}(M, M^{\text{Frob}})$, where Frob is the non-trivial element in $\text{Gal}(\mathbb{F}_{\ell^2}/\mathbb{F}_\ell)$.
Two tricks allow us to discard this case:

i) Suppose that for a prime $q$, $\text{Pol}_q(x)$ decomposes over $\mathbb{Q}$ as follows:

$$\text{Pol}_q(x) = (x^2 + Ax + q)(x^2 + Bx + q), \quad A \neq B.$$  
Then case (***) cannot hold if $\ell \nmid B - A$ and $\ell \neq q$.

ii) Suppose that $p^{2k+1} \parallel \text{cond}(A)$, then for every $\ell \nmid p\Phi(p)$, case (***) cannot hold. The condition on $\ell$ is imposed to ensure that for these $\ell$, $p^{2k+1} \parallel \text{cond}(\bar{\rho}_p)$ also holds.

EXAMPLE (Smart): The following curve is taken from the list given in [Sm 97] of all genus 2 curves defined over $\mathbb{Q}$ with good reduction away from 2:

$$C_3 : \quad y^2 = x(x^4 + 32x^3 + 336x^2 + 1152x - 64),$$

$A_3 = J(C_3), \quad c \mid 2^{20}$ (this is the uniform bound for the 2-part of the conductor of abelian surfaces over $\mathbb{Q}$, cf. [B-K 94]). Le Duff’s method cannot be applied to this example; the condition of proposition 5.1 is not verified at 2.

We eliminate ALL maximal proper subgroups in Mitchell’s classification using the characteristic polynomials $\text{Pol}_p(x)$ for several primes $p$ and $\text{cond}(\varepsilon) \mid 1024$, $S = \{1024\}$, with the algorithm described in section 3.

To be more precise, the reducible cases treated in section 3.1 and 3.2 are excluded using the polynomials $\text{Pol}_p(x)$ for $p = 3, 17, 19, 31$. Assuming Serre’s conjecture, the remaining reducible case is excluded using the polynomials $\text{Pol}_p(x)$ for $p = 7, 11, 13$. The cases considered in sections 3.4 and 3.5 are excluded using the polynomials $\text{Pol}_p(x)$ for $p = 3, 5$. Finally, with the technique described in section 3.7 we check that $\ell = 5, 7$ are non-exceptional.

All characteristic polynomials used are listed in section 6.

After these computations we find no exceptional primes. Then, we conclude

**Theorem 5.6** Assume Serre’s conjecture (3.2.A1) (cf. [Se 87]). Then the images of the Galois representations on the $\ell$-division points of $A_3$ are

$$G_\ell = \text{GSp}(4, \mathbb{F}_\ell), \quad \text{for every } \ell > 3.$$
Without Serre’s conjecture, trick (i) is used to discard case (**). In fact, 
$Pol_5(x)$ decomposes as in (i) with $A = -2$ and $B = 0$. The same happens to 
$Pol_{17}(x)$.

To deal with case (*) we check that $Pol_3(x)$ is irreducible and $\Delta_{Q_3} = 12$ (see 
section 6). We obtain the unconditional result:

**Theorem 5.7** The images of the Galois representations on the $\ell$-division 
points of $A_3$ are

$$G_\ell = \text{GSp}(4, \mathbb{F}_\ell), \quad \text{for every } \ell > 3 \quad \text{with} \quad \left(\frac{3}{\ell}\right) = -1.$$  

5.3 Further examples

In [Le 91], Leprvost gives a genus 2 curve over $\mathbb{Q}(t)$ with 13-rational torsion. 
For $t = 13$ we obtain:

$$C : \quad y^2 = -4x^5 + 300x^4 - 1404x^3 + 5408x^2 - 8788x + 28561,$$

$A = J(C)$ has $\text{cond}(A) = 2^a \cdot 13^3 \cdot 5^2 \cdot 17^2$. Le Duff’s condition is not verified at any prime. We can determine the image as in the previous example, with or without assuming Serre’s conjecture (in the “reducible case with 1-
dimensional constituent” we find $\ell = 13$ as exceptional prime).

Remark: Here trick (ii) eliminates case (**) for every $\ell \neq 13$ because 
$$13^3 \mid \text{cond}(A) \quad \text{and} \quad \Phi(13) = 13.$$  

Brumer and Kramer (unpublished) have given examples of jacobians of genus 2 curves with prime conductor. For them our algorithm determines the image with just a few computations. For instance, when applying Serre’s conjecture no computation is necessary because we have $S = \{1\}$ and $S_2(1) = 0$. 
One of these examples is given by the jacobian of the genus two curve:

$$C : \quad y^2 = x(x^2 + 1)(1729x^3 + 45568x^2 + 25088x - 76832).$$

The conductor of $J(C)$ is 709.

Remark: All the examples of abelian surfaces considered in this article verify the condition $\text{End}(A) = \mathbb{Z}$. This follows in particular from our result on the images of the attached Galois representations (the condition on the endomorphism algebra is also necessary for this result to hold).
6 Computed characteristic polynomials

We list all the characteristic polynomials $Pol_p(x)$ that have been used in the examples of the abelian surface $A$ in section 4 and the abelian surfaces $A_2$ and $A_3$ in section 5. Recall that in any case the polynomial $Pol_p(x)$ is of the form

$$x^4 - a_p x^3 + b_p x^2 - p a_p x + p^2$$

so it is enough to give the values $a_p, b_p$.

Abelian surface $A$ (section 4):

| $p$ | $a_p$ | $b_p$ |
|-----|-------|-------|
| 3   | -3    | 6     |
| 7   | -2    | 6     |
| 11  | -4    | 18    |
| 13  | -5    | 16    |
| 17  | 0     | 22    |
| 19  | -6    | 42    |
| 97  | 6     | 154   |
| 113 | 18    | 250   |
| 229 | 24    | 534   |
| 257 | 15    | 148   |
| 569 | 6     | -118  |
| 641 | 12    | -266  |
| 769 | -6    | 402   |
Abelian surface $A_2 = J(C_2)$ (section 5.1):

| $p$ | $a_p$ | $b_p$ |
|-----|-------|-------|
| 3   | -3    | 7     |
| 5   | -5    | 15    |
| 17  | -3    | 16    |
| 97  | -8    | 86    |
| 257 | -11   | -113  |
| 11  | -7    | 31    |
| 41  | -7    | 72    |
| 79  | 7     | 75    |
| 101 | -8    | -16   |
| 199 | 25    | 338   |
| 211 | -17   | 103   |
| 281 | 1     | 148   |

Abelian surface $A_3 = J(C_3)$ (section 5.2):

| $p$ | $a_p$ | $b_p$ |
|-----|-------|-------|
| 3   | 2     | 4     |
| 5   | 2     | 10    |
| 7   | -2    | 2     |
| 11  | -2    | 12    |
| 13  | -6    | 18    |
| 17  | 4     | 22    |
| 19  | -2    | -4    |
| 31  | 4     | 46    |
