Abstract

In the Minimal Supersymmetric Standard Model heavy superparticles introduce large logarithms in the calculation of the lightest CP-even Higgs boson mass. These logarithmic contributions can be resummed using effective field theory techniques. For light superparticles, however, fixed-order calculations are expected to be more accurate. To gain a precise prediction also for intermediate mass scales, both approaches have to be combined. Here, we report on an improvement of this method in various steps: the inclusion of electroweak contributions, of separate electroweakino and gluino thresholds, as well as resummation at the NNLL level. These improvements can lead to significant numerical effects. In most cases, the lightest CP-even Higgs boson mass is shifted downwards by about 1 GeV. This is mainly caused by higher order corrections to the MS top-quark mass. We also describe the implementation of the new contributions in the code FeynHiggs.
1 Introduction

With the discovery of the Higgs boson by the experiments ATLAS [1] and CMS [2] at the CERN Large Hadron Collider the Standard Model (SM) has been completed; there is, however, still ample room for Beyond Standard Model (BSM) physics. One of the best motivated and studied BSM models is the Minimal Supersymmetric Standard Model (MSSM) realizing the concept of supersymmetry (SUSY). It extends the Higgs sector of the SM by a second complex doublet leading to five physical Higgs particles ($h$, $H$, $A$ and $H^\pm$) and three (would-be) Goldstone bosons. The light CP-even state $h$ can be identified with the discovered boson. At the tree-level, the Higgs sector can be conveniently parametrized by the mass of the $A$ boson, $M_A$, and the ratio of the vacuum expectation values of the two doublets, $\tan \beta = v_2/v_1$.

So far, no direct hints for SUSY particles have been found. Still, the SUSY parameter space can be constrained indirectly by precision observables, with the Higgs-boson mass constituting an important precision observable on its own. Since the Higgs mass is strained indirectly by precision observables, with the Higgs-boson mass constituting an important precision observable, the MSSM Higgs sector is consistently combined with the fixed-order diagrammatic result. In Section 4, we discuss the implementation of the improvements in the next-to-next-to-leading logarithm (NNLL) level.

In the case of heavy SUSY particles, large logarithms appear in explicit diagrammatic calculations making a fixed-order calculation an unreliable tool. The origin of this problem is the large hierarchy between the electroweak scale and the SUSY scale. Effective field theory techniques allow to resum these large logarithms to all orders and thus get stable predictions. All of the effective coupling constants are fixed by matching them to physical observables at the electroweak scale [36], this concerns only the Higgs self-coupling $\lambda$. All of the other couplings of the EFT are fixed by matching them to physical observables at the electroweak scale [36], e.g. the top Yukawa coupling is extracted from the top-quark pole mass.

2 Effective field theory calculation

In the simplest EFT framework, all SUSY particles are assumed to share a common mass scale $M_S$ (this assumption will be relaxed below), where $M_S$ is the stop mass scale,

$$M_S = \sqrt{m_{\tilde{t}_1}m_{\tilde{t}_2}}.$$ (1)

and $m_{\tilde{t}_{1,2}}$ are the stop masses. This scale is furthermore assumed to be much heavier than the electroweak scale. Below $M_S$, all SUSY particles are integrated out from the full theory. Thus, the low energy effective theory below the SUSY scale is the SM.

The effective couplings of the EFT are fixed by matching to the full MSSM at the matching scale $M_S$ (in the simplest case of an effective SM below $M_S$, this concerns only the Higgs self-coupling $\lambda$). All of the other couplings of the EFT are fixed by matching them to physical observables at the electroweak scale [36], e.g. the top Yukawa coupling is extracted from the top-quark pole mass.
In the EFT framework, we calculate the Higgs mass via the relation
\[
(M_h^{\text{EFT}})^2 = \lambda(M_t)v^2,
\] (2)
with the self-coupling \(\lambda\) evaluated at the top-quark pole mass \(M_t\) and with the electroweak vacuum expectation value \(v\) (see [37] and references therein). Since all SUSY particles are integrated out at the electroweak scale, this ensures that all large logarithms which would appear explicitly in a diagrammatic calculation in the full model framework are contained in \(\lambda(M_t)\). \(\lambda(M_t)\) is obtained via renormalization group equations (RGEs) from \(\lambda(M_S)\), which is determined by matching \(\lambda\) to the full MSSM at \(M_S\). The running between \(M_S\) and \(M_t\) corresponds to a resummation of large logarithms.

For the resummation of leading logarithms (LL), one-loop RGEs and tree-level matching conditions are needed; for the resummation of leading and next-to-leading logarithms (NLL), two-loop RGEs and one-loop matching conditions, and, accordingly, for the resummation of leading, next-to-leading and next-to-next-to-leading logarithms, three-loop RGEs and two-loop matching conditions.

### 2.1 Electroweak contributions

As a first improvement with respect to [31], we include electroweak contributions in the resummation procedure at the NLL level. Correspondingly, we use the full two-loop RGEs of the SM (see [36] and references therein), including terms proportional to the electroweak gauge couplings \(g\) and \(g'\) (for \(SU(2)\) and \(U(1)\)), to evolve the SM couplings.

Furthermore, the threshold correction of the Higgs self-coupling at the SUSY scale has to be extended at the one-loop level by adding the various electroweak one-loop contributions,
\[
\lambda_{\text{SM}}(M_S) = \frac{1}{4}(g^2 + g'^2)\cos^2(2\beta) + \Delta_{\text{stop}}\lambda + \Delta_{\text{heavyH}}\lambda + \Delta_{\text{EWino}}\lambda + \Delta_{\text{DR-MSSM}}\lambda.
\] (3)

\(\Delta_{\text{stop}}\lambda\) is the contribution from the top and stop sector (extended by electroweak contributions in comparison to [31]); \(\Delta_{\text{heavyH}}\lambda\), the contribution from the heavy non-SM Higgs bosons; \(\Delta_{\text{EWino}}\lambda\) the contribution from charginos and neutralinos. The term \(\Delta_{\text{DR-MSSM}}\lambda\) accounts for the fact that the tree-level contribution is expressed in terms of MSS-renormalized gauge couplings of the SM and not in terms of DR-renormalized gauge couplings of the MSSM. All of these threshold corrections have been derived in previous works [17,23,26,27]. We use the expressions given in [27]. Accordingly, also the relations used to extract SM gauge and Yukawa couplings from physical observables at \(M_t\) must include electroweak one-loop corrections [36]. This is especially relevant for the MSS top-quark mass, respectively the top Yukawa coupling, as will be discussed later in the section on results.

### 2.2 Gaugino–higgsino thresholds

The assumption of a common mass scale for all SUSY particle is quite limiting. To allow for electroweakinos (charginos and neutralinos) lighter than \(M_S\) (but still much heavier than the electroweak scale), we introduce an additional electroweakino threshold \(M_\chi\). We assume that all charginos and neutralinos are nearly mass degenerate (having the mass \(M_\chi\)),
\[
M_\chi = M_1 = M_2 = \mu \text{ with } M_Z \ll M_\chi \lesssim M_S,
\] (4)
where \(M_1\) and \(M_2\) are the electroweak gaugino soft-breaking masses and \(\mu\) is the Higgsino mass parameter.

This means that at \(M_S\) all SUSY particles but charginos and neutralinos are integrated out. The corresponding EFT below \(M_S\), the split model, is the SM with charginos and neutralinos added. The corresponding effective Lagrangian reads [27]
\[
\mathcal{L}_{\text{split}} = \mathcal{L}_{\text{SM}} + \cdots - \frac{1}{2} M_\chi \tilde{W}^a \tilde{W}_a - \frac{1}{2} M_\chi \tilde{B}\tilde{B} - M_\chi \tilde{H}_2 \cdot \tilde{H}_1 \\
- \frac{1}{\sqrt{2}} H^\dagger \left( \tilde{g}_{2u} \sigma^a \tilde{W}_a + \tilde{g}_{1u} \tilde{B} \right) \tilde{H}_u - \frac{1}{\sqrt{2}} H \cdot \left( -\tilde{g}_{2d} \sigma^a \tilde{W}_a + \tilde{g}_{1d} \tilde{B} \right) \tilde{H}_d + h.c.
\] (5)
The bino field is denoted by \(\tilde{B}\), the wino field by \(\tilde{W}\) and the higgsino fields by \(\tilde{H}_{u,d}\). The ellipsis stands for the associated kinetic terms. The effective Higgs-Higgsino-gaugino couplings are labeled \(\tilde{g}_{1u,d}\). The number in the subscript refers to the symmetry group \(U(1)\) or \(SU(2)\), the letter to the involved Higgs doublet. These effective couplings are determined by a one-loop matching of the split model to the full MSSM at the scale...
All couplings are evolved between the electroweakino scale and the stop mass scale using two-loop split model RGEs, which can be found in [35, 28].

At the scale \( M_{\tilde{t}} \), all electroweakinos are integrated out, and the remaining EFT below \( M_{\tilde{t}} \) is the SM. We match the SM to the split model using the threshold corrections given in [35, 28], i.e. the term \( \Delta_{\text{EWino}} \) in Eq. (5) is now part of the matching condition of \( \lambda \) at \( M_{\tilde{t}} \). Also the top Yukawa coupling receives a threshold correction at the electroweakino scale. Below \( M_{\tilde{t}} \), the SM RGEs are used for evolving the couplings.

In addition to allowing for light charginos and neutralinos, we also consider the case of a light gluino. This case is implemented by introducing an additional threshold marked by the gluino mass \( M_{\tilde{G}} \), below which the gluino is integrated out. The gluino is also assumed to be much heavier than the electroweak scale such that eventually the system is recovered as the EFT close to the electroweak scale. However, no assumption about the ordering of \( M_{\tilde{G}} \) and \( M_{\tilde{t}} \) is made, i.e. \( M_{\tilde{G}} \leq M_{\tilde{t}} \) as well as \( M_{\tilde{G}} > M_{\tilde{t}} \) is allowed. Since the gluino does not couple directly to the Higgs boson, no additional one-loop matching condition for \( \lambda \) has to be considered. The same argument applies for the electroweak gauge couplings, the Yukawa couplings (in the absence of sfermions) and the effective Higgs-Higgsino-gaugino couplings of the split model. An explicit calculation also shows that the strong gauge coupling does not receive a threshold correction. However, the presence of the gluino in the EFT above \( M_{\tilde{G}} \) modifies the RGEs (see App. A).

### 2.3 NNLL resummation

As a further improvement, we include resummation at the NNLL level. This is restricted to the dominating contributions resulting from the top Yukawa coupling \( y_t \), respectively \( \alpha_t = g_t^2 / 4\pi \), and the strong gauge coupling \( g_s \), respectively \( \alpha_s = g_s^2 / 4\pi \). NNLL resummation requires two-loop threshold corrections. Therefore, we extend Eq. (3) by the corresponding two-loop contributions,

\[
\lambda_{\text{SM}}(M_S) = \frac{1}{4} (g^2 + g_s^2) \cos^2(2\beta) + \Delta_{\text{stop}} \lambda + \Delta_{\text{heavyR}} \lambda + \Delta_{\text{EWino}} \lambda + \Delta_{\text{DR,MS}} \lambda + \Delta_{\alpha_s, \alpha_t} \lambda + \Delta_{\alpha_t^2} \lambda. \tag{6}
\]

These terms have already been calculated based on the work of [29] and [27]; the pure top Yukawa correction \( \mathcal{O}(\alpha_t) \) corrections are given in [29] and [27]; the pure top Yukawa correction \( \mathcal{O}(\alpha_t^2) \) are listed in [29] and in a slightly different form in [30]. The matching condition for the top Yukawa coupling involves the \( \text{MS} \) top-quark mass which for NNLL resummation is obtained from the pole mass by means of the standard QCD and top Yukawa corrections at the two-loop level [36].

Furthermore, three-loop RGEs are needed for the coupling constant evolution. Since only NNL logarithms of \( \mathcal{O}(\alpha_s, \alpha_t) \) are resummed in this step, we neglect the electroweak gauge couplings at the three-loop level of the needed RGEs. All couplings of electroweakinos, being present below \( M_S \) for \( M_{\tilde{t}} < M_S \), are proportional to the electroweak gauge couplings when their matching conditions at \( M_S \) are plugged in. In consequence, their presence has no influence on the form of the three-loop RGEs at this level of approximation. Hence for all considered hierarchies at all scales below \( M_S \), the needed three-loop RGEs are just the corresponding SM RGEs, which are well known [38, 44]. The same argument implies that the two-loop matching conditions of \( \lambda \) do not have to be modified for \( M_{\tilde{G}} \) lower than \( M_S \).

For NNLL resummation, we have to restrict ourselves to the case of \( M_{\tilde{G}} \) equal to \( M_S \) in the resummation procedure, since three-loop RGEs for the SM with added gluino are not known. Nevertheless, the numerical effect of a gluino threshold is so small that it can be safely neglected, as will be seen in the numerical results.

### 3 Combining fixed-order and EFT calculations

The final prediction for the physical Higgs mass is obtained by adding the fixed-order result achieved by a Feynman-diagrammatic calculation and the result obtained from the effective field theory method with appropriate subtractions in order to avoid double-counting of terms already contained in the fixed-order expressions (see also [31]),

\[
\begin{align*}
M_h^2 &= (M^2_h)_{\text{FD}} + (X_t^{\text{OS}}) + \Delta M^2_h, \tag{7} \\
\Delta M^2_h &= (M^2_h)_{\text{EFT}} (X_t^{\text{DR}}) - (\Delta M^2_h)^{\text{1L,2L logs}} (X_t^{\text{OS}}) \\
&\quad - (\Delta M^2_h)^{\text{EFT, non-log}} (X_t^{\text{OS}}). \tag{8}
\end{align*}
\]
where $X_i$ is the mixing parameter in the stop squared-mass matrix. $(M_h^2)^{\text{FD}}$ denotes the one- and two-loop fixed-order Feynman-diagrammatic result in the on-shell renormalization scheme, as implemented in \texttt{FeynHiggs}. $\Delta M_h^2$ is the result of the resummation beyond two-loop order, which consists of the result of the EFT calculation $(M_h^2)^{\text{EFT}}$ together with the proper subtraction terms. $(M_h^2)^{\text{EFT}}$ is obtained via Eq. \ref{eq:2} from the RGEs and threshold corrections involving the SUSY parameter $X_i$ defined in the $\overline{\text{DR}}$-scheme at the scale $M_S$.

The first subtraction term $(\Delta M_h^2)^{\text{1L,2L logs}}$ ensures that the one- and two-loop logarithms in the OS scheme, already contained in the Feynman-diagrammatic result, are not counted twice. We extracted these logarithms in the EFT framework by solving the system of RGEs iteratively and converting to the OS scheme afterwards. As a cross-check, we also identified the one-loop logarithms within the Feynman-diagrammatic result finding agreement (see \ref{eq:3} for explicit expressions). It should be noted that \texttt{FeynHiggs} afterwards. As a cross-check, we also identified the one-loop logarithms within the Feynman-diagrammatic result, i.e. as obtained with a $\overline{\text{MS}}$ top-quark mass. If this option is switched on, we have to subtract the one- and two-loop logarithms as contained in the Feynman-diagrammatic result, i.e. as obtained with a $\overline{\text{MS}}$ top-quark mass.

The second subtraction term $(\Delta M_h^2)^{\text{non-log}}$ is introduced to cancel all non-logarithmic terms contained in the EFT result. They originate from the matching conditions of the Higgs self-coupling and have to be subtracted when only higher-order logarithmic contributions are added to the Feynman-diagrammatic result.

A particular issue to be taken care of when combining the diagrammatic result with the EFT calculation, is the choice of the renormalization scheme. The EFT calculation uses minimal subtraction schemes ($\overline{\text{DR}}$ for scales above $M_S$, $\overline{\text{MS}}$ for scales below $M_S$) for renormalization. In contrast, in the diagrammatic calculation a mixed OS/$\overline{\text{DR}}$ scheme is employed (see \ref{eq:33} for a detailed description). Consequently, the input parameters of the EFT calculation are $\overline{\text{MS}}$/DR parameters, whereas they are OS parameters in the diagrammatic calculation \ref{eq:22}, as indicated in Eq. \ref{eq:7}. The logarithmic subtraction term takes OS parameters as input, because we want to avoid double-counting of the one- and two-loop logarithms in the OS scheme. Also the non-logarithmic subtraction term takes OS parameters as input, although the non-logarithmic terms contained in the EFT result are parametrized with $\overline{\text{DR}}$ parameters. This is owing to the fact that non-logarithmic terms in the $\overline{\text{DR}}$ scheme lead to logarithmic terms in the OS scheme: consequently, the OS two-loop logarithms of the Feynman-diagrammatic result would not be reproduced when $\overline{\text{DR}}$ parameters were used as input.

We choose to work with OS parameters as principal input. This means that OS input parameters are converted to $\overline{\text{DR}}$ parameters when used as input for the EFT calculation. We restrict ourselves to a one-loop conversion involving only terms proportional to large logarithms. This conversion is sufficient to reproduce all large logarithms already contained in the diagrammatic two-loop result of \texttt{FeynHiggs}. In contrast, non-logarithmic terms and higher loop-order terms would lead to terms in the EFT result which correspond to unknown higher-order corrections in an OS renormalized diagrammatic result. We however intend to add the resummed logarithms as obtained in the $\overline{\text{MS}}$/DR scheme to the diagrammatic result. In consequence, all terms beyond one-loop logarithms have to be omitted.

The main input parameters of the EFT calculation are the stop mass scale $M_S$ and the stop mixing parameter $X_i$. The conversion of $M_S$ does not involve any large logarithms \cite{20,31}; hence, $M_S$ is not converted. The conversion of $X_i$ at $O(\alpha_s, \alpha)$ is given by\footnote{The $X_i^2$ term is missing in \cite{31}, but it is properly included in \texttt{FeynHiggs} and in agreement with \cite{20}.}

$$X_i^{\overline{\text{DR}}} = X_i^{\overline{\text{OS}}} \left[ 1 + \left( \frac{\alpha_s}{\pi} - \frac{3\alpha_s}{16\pi} (1 - X_i^2 / M_S^2) \right) \ln \frac{M_S^2}{M_i^2} \right].$$ \quad \text{(9)}$$

The only other input parameters in our EFT calculation are the intermediate electroweakino mass scale $M_X$ and the gluino mass $M_{\tilde{g}}$. Since the diagrammatic \texttt{FeynHiggs} result so far contains two-loop corrections only in the gaugeless limit, a conversion of $M_X$, which would contain only terms proportional to the electroweak gauge couplings, is not needed. Since the gluino mass appears first at the two-loop level, also a conversion of $M_{\tilde{g}}$ is not necessary.

A further issue to be discussed is the treatment of $\tan \beta$. In the EFT approach, $\tan \beta$ appears only in the matching condition of $\lambda$ at the SUSY scale $M_S$. This means that the $\overline{\text{DR}}$-renormalized $\tan \beta(M_S)$ is required as an input of the EFT calculation. In the Feynman-diagrammatic calculation, $\tan \beta$ is also a $\overline{\text{DR}}$-renormalized quantity. In \texttt{FeynHiggs}, the corresponding renormalization scale, however, is chosen to be $M_i$ and not $M_S$ \cite{33}. In consequence, we need to relate $\tan \beta(M_i)$, which is used as input of the overall calculation, to $\tan \beta(M_S)$. This presents a problem, since there is no proper way to define $\tan \beta$ in the EFT below $M_S$, where the non SM-like Higgs bosons are integrated out. This problem has already been noted in \cite{23}. We find that without a running of $\tan \beta$ the EFT calculation does not reproduce the one-loop
result of the Feynmann diagrammatic calculation (see [B] for explicit expressions). This strongly motivates
to evolve \( \tan \beta \) between \( M_t \) and \( M_S \) despite the lack of a rigoros definition. In practice, we regard \( \tan \beta \) as a high-energy parameter with an evolution according to the one-loop RGE of the MSSM [23],

\[
\frac{1}{\tan^2 \beta} \frac{d \tan \beta}{d \ln Q^2} = \frac{-3}{16\pi^2} h_t^2,
\]

(10)

which is determined by the anomalous dimensions of the Higgs fields, with contributions only from the top-
quark loops. The parameter \( h_t \) denotes the MSSM top Yukawa coupling, which at lowest order is related to
the SM top Yukawa coupling \( y_t \) by

\[
y_t = h_t \sin \beta.
\]

(11)

Rewriting the RGE in terms of \( y_t \) yields

\[
\frac{1}{1 + \tan^2 \beta} \frac{d \tan^2 \beta}{d \ln Q^2} = \frac{-3}{16\pi^2} y_t^2.
\]

(12)

Since only SM entries contribute to the running [23], the RGE has not to be modified for scales below
\( M_S \), even if passing an intermediate threshold. This method reproduces correctly the one-loop result of the
diagrammatic calculation, as given in [B]. In principle, for a NLL resummation also the two-loop RGE should
be employed, which for the MSSM can be found in [45, 46]. It is, however, unclear which contributions of
the two-loop RGE are due to SM particles and which are due to their supersymmetric partners. From a
practical point of view, numerical checks suggest that the two-loop running is negligible. Therefore, only the
one-loop RGE is used in this work.

4 Implementation in FeynHiggs

As explained in [31], the shift \( \Delta M^2_\phi \) is implemented in FeynHiggs by adding it with a factor \( 1/\sin^2 \beta \) to
the \( \phi_2\phi_2 \) self-energy (\( \phi_2 \) is the \( \mathcal{CP} \)-even neutral component of the second Higgs doublet). In this way, the
result of the resummation procedure enters also the calculation of other observables that are available from
FeynHiggs.

The improved resummation of large logarithms is available in FeynHiggs from version 2.12.0 on. In this
version, the new flag loglevel is introduced to control the resummation procedure. The various options are

- loglevel=0: no resummation;
- loglevel=1: \( \mathcal{O}(\alpha_s, \alpha_t) \) LL and NLL resummation (corresponds to former loglevel=3);
- loglevel=2: full LL and NLL resummation;
- loglevel=3: full LL, NLL and \( \mathcal{O}(\alpha_s, \alpha_t) \) NNLL resummation.

For loglevel greater than one, electroweak NLO corrections to the \( \overline{\text{MS}} \) top-quark mass are switched on
automatically.

So far, all matching conditions are only implemented for degenerate soft-breaking masses, meaning that
all soft-breaking masses are set equal to their corresponding threshold scale. The diagrammatic part of the
calculation, however, captures the effects of non-degeneracy in an exact way at the one- and two-loop level.
The matching condition will be extended to the non-degenerate case in a future update to FeynHiggs.

5 Numerical analysis

To analyse the numerical impact of the improved resummations, we first compare the results of the previous
FeynHiggs version 2.11.3 with the new version 2.12.0. As an example case, we look at a scenario where
all soft-breaking masses as well as the Higgsino mass parameter are chosen to be equal to \( M_S \), together
with \( t_\beta \equiv \tan \beta = 10 \). The results of FeynHiggs2.11.3 are obtained with switched on \( \mathcal{O}(\alpha_s, \alpha_t) \) LL and
NLL resummation. Also the two-loop QCD correction to the \( \overline{\text{MS}} \) top-quark mass are enabled, although
no NNLL resummation is performed. This is done because of the large numerical impact of this two-loop
correction on the Higgs mass calculation (see the discussion at the end of this section). For the results of
FeynHiggs2.12.0, all improvements discussed above are activated (loglevel=3).
Figure 1: Left: $M_h$ as a function of $M_S$ for $X_t/M_S = 0$ (solid) and $X_t/M_S = 2$ (dashed). The results of FeynHiggs2.11.3 (blue) are compared to the results of FeynHiggs2.12.0 (red). Right: $M_h$ as a function of $X_t/M_S$ for $M_S = 1$ TeV (solid) and $M_S = 5$ TeV (dashed). The results of FeynHiggs2.11.3 (blue) are compared to the results of FeynHiggs2.12.0 (red).

Figure 2: Left: $M_h$ as a function of $M_S$ for $X_t/M_S = 0$ (solid) and $X_t/M_S = 2$ (dashed). The results with (orange) and without (blue) resummation of electroweak logarithms (LL+NLL) are compared. Furthermore, the result without resummation of electroweak logarithms but with electroweak NLO corrections to the $\overline{\text{MS}}$ top-quark mass (red) are shown. Right: The results with resummation of electroweak logarithms at the LL and NLL level (blue) and at the LL level only (red) are compared.

The comparison is displayed in Fig. 1 where the left panel shows $M_h$ as a function of $M_S$ for unmixed squarks with $X_t/M_S = 0$ and for the mixed case with $X_t/M_S = 2$. For vanishing stop mixing, we observe a small downwards shift of $\lesssim 0.8$ GeV over the whole $M_S$ range, and a bit more for $X_t/M_S = 2$, of $\lesssim 1.7$ GeV. The right panel in Fig. 1 shows $M_h$ as a function of $X_t/M_S$ for $M_S = 1$ TeV and $M_S = 5$ TeV. We observe a smaller shift for negative values of $X_t$; e.g. for $M_S = 1$ TeV the difference between FeynHiggs2.11.3 and FeynHiggs2.12.0 is $\sim 0.6$ GeV for $X_t/M_S = -2$, whereas it amounts to $\sim 1.6$ GeV for $X_t/M_S = 2$.

To explore the origin of these shifts, we examine first the contribution of the resummation of logarithms proportional to the electroweak gauge couplings. The left panel of Fig. 2 shows $M_h$ as a function of $X_t/M_S$ for $X_t/M_S = 0$ and $X_t/M_S = 2$. The results with a resummation of logarithms proportional to the electroweak gauge couplings (loglevel=2) and without such a resummation are compared (loglevel=1). The latter corresponds, apart from some minor fixes, to the result of FeynHiggs2.11.3. Furthermore, the result without resummation of logarithms proportional to the electroweak gauge couplings but with electroweak NLO corrections to the $\overline{\text{MS}}$ top mass is shown. For vanishing stop mixing, we observe a downwards shift of $\sim 1.2$ GeV for $M_S = 1$ TeV. This shift is almost completely caused by the electroweak NLO corrections to the $\overline{\text{MS}}$ top mass yielding a reduction of the $\overline{\text{MS}}$ top mass by 1.1 GeV. This translates directly to a downwards shift of $M_h$. For $M_S = 1$ TeV, the downwards shift caused by the corrections to the $\overline{\text{MS}}$ top mass is more and more compensated by the upwards shift caused by the resummed logarithms proportional to the electroweak gauge couplings. For $X_t/M_S = 2$, the behavior is very similar. For $M_S = 1$ TeV, the downwards shift is larger ($\sim 1.7$ GeV) owing to the increased dependence on the $\overline{\text{MS}}$ top mass for nearly
maximal stop mixing. For rising $M_S$, this downwards shift is again more and more compensated by the positive contributions of the resummed electroweak logarithms.

The right panel of Fig. 2 shows $M_h$ as a function of $M_S$ for $X_t/M_S = 0$ and $X_t/M_S = 2$. The results with a resummation of logarithms proportional to the electroweak gauge couplings at the LL and NLL level (loglevel=2) and with a resummation of logarithms proportional to the electroweak gauge couplings at the LL level and vanishing electroweak gauge couplings at the NLL level are compared. We observe that the effect of a NLL resummation of electroweak logarithms is $\lesssim 0.5$ GeV over the whole $M_S$ range for both vanishing and nearly maximal mixing. This shows the minor importance of the electroweak NLL resummation in comparison to electroweak LL resummation, which leads to shifts of up to 2.5 GeV for $M_S \sim 20$ TeV.

The effect of the electroweakino threshold is investigated in the left panel of Fig. 3, which displays $M_h$ as function of $M_S$ for $X_t/M_S = 0$ and $X_t/M_S = 2$. In contrast to the previous figures, the electroweakino mass scale $M_\chi$ is not chosen to be equal to $M_S$, but is fixed to 1 TeV. To disentangle the effect of the electroweakino threshold in the EFT calculation from the fixed-order one-loop corrections due to neutralinos and charginos, we compare the results with a electroweakino threshold to the results without a separate electroweakino threshold. To get the results without a separate electroweakino threshold, we set $M_\chi = M_S$ in the EFT calculation (namely in $\Delta M_\chi^2$), but keep $M_\chi = 1$ TeV in the Feynman-diagrammatic calculation. The plot clearly shows that the implementation of a separate electroweakino threshold becomes only relevant for $M_S \gtrsim 5$ TeV. This behavior does not depend on the size of the stop mixing.

The effect of a separate gluino threshold is found to be negligible. For $M_S$ between 1 TeV and 20 TeV, its inclusion shifts $M_h$ downwards by at most 0.2 GeV for $|X_t/M_S| \leq 2$. The diagrammatic two-loop corrections capture almost the entire effect of varying $M_S$, which can be sizeable ($\sim 2$ GeV) for maximal mixing. This justifies to set $M_S = M_S$ in the resummation procedure in the case of NNLL resummation, as explained in Section 2.

In the right panel of Fig. 3, the difference between the results without (loglevel=2) and with (loglevel=3) NNLL resummation as a function of $X_t/M_S$ is shown for $M_S = 1$ TeV, $M_S = 2$ TeV and $M_S = 5$ TeV. Between $X_t/M_S \sim -1$ and $X_t/M_S \sim 1.5$, we observe only small shifts ($\lesssim 0.3$ GeV). For $X_t/M_S \sim -2$, $M_h$ is shifted upwards by the inclusion of NNLL resummation by up to 1 GeV, whereas $M_h$ is shifted downwards by up to 0.5 GeV for $X_t/M_S = 2$. This behavior is mainly caused by the $O(\alpha_s \alpha_t)$ matching condition of $\lambda$, which exhibits a similar dependence on $X_t/M_S$. The large positive shift for negative $X_t$ compensates the downwards shift originating from the electroweak NLO correction to the $M_S$ top-quark mass. This downwards shift is however enhanced by the negative shift for positive $X_t$. This is the reason for the asymmetric behaviour observed in the right panel of Fig. 1.

Note that the comparison made in the right panel of Fig. 3 does not exhibit the effect of the two-loop corrections to the $\overline{\text{MS}}$ top mass, since also for the curve without NNLL resummation the two-loop QCD corrections in the $\overline{\text{MS}}$-mass – pole-mass relation are employed. We have kept them because they constitute the by far dominant part of the two-loop corrections to the $\overline{\text{MS}}$ top mass, shifting the $\overline{\text{MS}}$ top mass down by 1.9 GeV. This downwards shift causes a downwards shift in $M_h$ of about the same size, as discussed before in the context of the electroweak NLO corrections to the $\overline{\text{MS}}$ top mass. Two-loop corrections to the $\overline{\text{MS}}$ top mass are formally not needed in the case of LL and NLL resummation. This means actually that the main
effect of going from NLL to NNLL resummation is caused by the higher-order matching condition of the \( \overline{\text{MS}} \) top mass, as in the case of including electroweak corrections into the resummation procedure.

6 Conclusions

We have presented and discussed the inclusion of electroweak contributions, electroweakino and gluino thresholds, and NNLL resummation in the EFT resummation of logarithmically enhanced terms in the calculation of the lightest Higgs boson mass \( M_h \), on top of the fixed-order one- and two-loop computation as currently available in the code \texttt{FeynHiggs}. Special attention is paid to a consistent combination of fixed-order diagrammatic and EFT methods taking care of scheme conversion and proper subtractions to avoid double counting. These improvements have become part of \texttt{FeynHiggs}. They shift the prediction for \( M_h \), especially pronounced for positive values of the stop-mixing parameter \( X_t \) with downwards shifts in \( M_h \) of about 1.7 GeV.

We found that this is mainly caused by the electroweak NLO corrections to the \( \overline{\text{MS}} \) top-quark mass. The genuine effect of resumming electroweak contributions shifts the Higgs mass upwards compensating the downwards shift induced by the smaller \( \overline{\text{MS}} \) top-quark mass. This effect becomes only relevant for SUSY scales larger than a few TeV. Furthermore, electroweak NLL contributions are found to be much smaller than electroweak LL contributions.

We also investigated the effect of various intermediate thresholds. In our framework, an electroweakino threshold yields significant contributions only for SUSY scales above 5 TeV. We found that a gluino threshold is completely negligible, since the main contributions sensitive to the gluino mass are already captured by the two-loop Feynman-diagrammatic result.

Furthermore, we found NNLL resummation of \( \mathcal{O}(\alpha_s, \alpha_t) \) to shift the lightest Higgs mass downwards for positive stop mixing, whereas it leads to a larger upwards shift for negative values of \( X_t \).

We aim to compare the results thoroughly to other publicly available codes \[30, 48\] in an upcoming publication. We also plan to extend the resummation procedure to scenarios with light non-SM Higgs bosons \[28, 49\].

Acknowledgments

We are thankful to Thomas Hahn for his invaluable help concerning all issues related to \texttt{FeynHiggs}, and to Sven Heinemeyer and Georg Weiglein for useful discussions.

A RGEs for SM with gluinos

The RGEs for the SM with an added gluino are extracted from the RGEs listed in \[26\]. The authors of \[26\] considered a split model, where all gauginos and higgsinos are assumed to be mass degenerate. In order to get the gluino part separately we had to disentangle the gluino and electroweakino contributions in the RGEs of \[26\]. The extracted RGEs have been crosschecked using \texttt{SARAH}, version 4.9 \[50\].

The normalization of \( \lambda \) and \( v \) is fixed by the following convention for the SM Higgs potential,

\[
V(\Phi) = -\frac{m^2}{2} \Phi^\dagger \Phi + \frac{\lambda}{2} (\Phi^\dagger \Phi)^2,
\]

with the SM Higgs doublet

\[
\Phi = \left( \frac{1}{\sqrt{2}} (v + h + i G^0) \right).
\]
Using this convention, the RGEs below and above the gluino threshold are given by

\[
\frac{dg_3^2}{d\ln Q^2} = \frac{g_3^4}{4\pi^2} \left[ - (7; 5) \right] + \frac{g_3^4}{(4\pi)^4} \left[ - (26; -22) g_3^2 - 2 g_1^2 \right].
\]  \tag{15a}

\[
\frac{dy_t^2}{d\ln Q^2} = \frac{y_t^2}{(4\pi)^4} \left[ \frac{9}{2} y_t^2 - 8 g_3^2 \right]
+ \frac{y_t^2}{(4\pi)^4} \left[ y_t^2 \left( - 12 y_t^2 - 6 \lambda + 36 g_3^2 \right) + \frac{3}{2} \lambda^2 - \left( 108; -\frac{284}{3} \right) g_3^4 \right],
\]  \tag{15b}

\[
\frac{d\lambda}{d\ln Q^2} = \frac{6}{(4\pi)^4} \left[ \lambda^2 + \lambda y_t^2 - y_t^4 \right]
+ \frac{1}{(4\pi)^4} \left[ y_t^2 (30 y_t^2 - 32 g_3^2) + \lambda y_t^2 (40 y_t^2 - \frac{3}{2} y_t^4) - 36 \lambda^2 y_t^2 - 39 \lambda^3 \right].
\]  \tag{15c}

The notation \(\langle a; b \rangle\) indicates that \(a\) is to be used for scales below \(M_{\tilde{g}}\) and \(b\) for scales above \(M_{\tilde{g}}\). For clarity, we omit terms proportional to the electroweak gauge couplings or the effective Higgs-Higgsino-gaugino couplings, which are not modified by the presence of the gluino.

## B  Explicit one-loop expressions

Extracting all one-loop leading logarithms out of the Feynman-diagrammatic result yields

\[
(M_{H^\pm}^2)^{1\text{-LL}} = M_{\tilde{g}}^2 c_{2\beta}(M_t) \left\{ - \frac{3}{8} \left[ 288 m_t^4 + 144 m_t^2 M_{\tilde{g}}^2 c_{2\beta} + 296 M_{W^\pm}^2 - 336 M_{W^\pm}^2 M_{\tilde{g}}^2 + 189 M_{\tilde{g}}^4 \right] 
+ 4 \left[ (62 M_{W^\pm}^4 - 84 M_{W^\pm}^2 M_{\tilde{g}}^2 + 39 M_{\tilde{g}}^4) c_{4\beta} - 9 M_{\tilde{g}}^2 c_{8\beta} \right] \ln \frac{M_{\tilde{g}}^2}{M_t^2} 
+ 3 \left[ 44 M_{W^\pm}^4 - 10 M_{W^\pm}^2 M_{\tilde{g}}^2 + 11 M_{\tilde{g}}^2 + \left( 20 M_{W^\pm}^2 - 10 M_{W^\pm}^2 M_{\tilde{g}}^2 - M_{\tilde{g}}^4 \right) c_{4\beta} \right] \ln \frac{M_{\tilde{g}}^2}{M_t^2} \right\},
\]  \tag{16}

where \(M_{Z} (M_W)\) is the mass of the \(Z\) (\(W\)) boson, \(m_t\) is the top-quark mass used to parametrize the diagrammatic result (i.e. OS mass or \(\overline{MS}\) mass) and the abbreviation \(c_x \equiv \cos x\) is used. The terms proportional to \(\ln(M_{\tilde{g}}^2/M_t^2)\) originate from charginos and neutralinos. The contributions of all other sectors yield the terms proportional to \(\ln(M_{\tilde{g}}^2/M_{\tilde{g}}^2)\).

On the other hand, the EFT calculation yields

\[
(M_{H^\pm}^2)^{1\text{-LL}} = M_{\tilde{g}}^2 c_{2\beta}(M_S) \left\{ - \frac{3}{8} \left[ 288 m_t^4 + 144 m_t^2 M_{\tilde{g}}^2 c_{2\beta} + 296 M_{W^\pm}^2 - 336 M_{W^\pm}^2 M_{\tilde{g}}^2 + 189 M_{\tilde{g}}^4 \right] 
+ 4 \left[ (62 M_{W^\pm}^4 - 84 M_{W^\pm}^2 M_{\tilde{g}}^2 + 39 M_{\tilde{g}}^4) c_{4\beta} - 9 M_{\tilde{g}}^2 c_{8\beta} \right] \ln \frac{M_{\tilde{g}}^2}{M_t^2} 
+ 3 \left[ 44 M_{W^\pm}^4 - 10 M_{W^\pm}^2 M_{\tilde{g}}^2 + 11 M_{\tilde{g}}^2 + \left( 20 M_{W^\pm}^2 - 10 M_{W^\pm}^2 M_{\tilde{g}}^2 - M_{\tilde{g}}^4 \right) c_{4\beta} \right] \ln \frac{M_{\tilde{g}}^2}{M_t^2} \right\}.
\]  \tag{17}

Using the dominant one-loop RGE for \(\tan\beta\) as explained in Section 3

\[
c_{2\beta}(M_S) = c_{2\beta}(M_t) + \frac{3}{2\pi^2} \frac{m_t^2}{v^4} c_{2\beta} \ln \frac{M_S^2}{M_t^2} + ..., \tag{18}
\]

we recover the result of the diagrammatic calculation.
