Abstract—Understanding the properties exhibited by Spatio-temporal evolution of cyber attacks improves cyber threat intelligence. In addition, better understanding on threats patterns is a key feature for cyber threats prevention, detection, and management and for enhancing defenses. In this work, we study different aspects of emerging threats in the wild shared by 160,000 global participants. First, we perform an exploratory data analysis of the collected cyber threats. We identify the most targeted countries, most common malwares and the distribution of attacks frequency by localisation. Second, we extract attacks’ spreading patterns at country level. We model these behaviors using transition graphs decorated with probabilities of switching from a country to another. Finally, we analyse the extent to which cyber threats have been affected by the COVID-19 outbreak and sanitary measures imposed by governments to prevent the virus from spreading.

Index Terms—Cyber attack analysis, Threat intelligence, Spatial-temporal data analysis for cyber-crime analysis, Cyber threats forecasting, COVID-19.

I. INTRODUCTION

Cyber threats and vulnerabilities are constantly emerging and are becoming complex and diverse with the evolution of technology. These emerging threats can lead to devastating attacks causing loss of confidential data, money and reputation damage [1]. In addition, due to the current covid-19 pandemic witnessed an explosion in the number of cyber attacks as most activities moved to operate online, affecting both individuals and organizations. This urges organizations to work towards a community driven approach to enable a strong exchange of information, knowledge and intelligence about these threats. In this sense, organizations are joining forces and sharing Cyber Threat Intelligence (CTI) through various platforms such as CINS score[1], Blocklist.de[2], Abuse.ch[3] and AlienVault OTX[4].

As organizations increasingly adhere to this process, the number of events and incidents shared is increasing exponentially. Hence, automated mining and analysis of information on these platforms is of vital importance. Understanding the specifics of shared information and turning them into actionable insights would help organizations anticipate cyberattacks and mitigate their adverse effects [2].

Cyber Attacks in the Era of Covid-19: The fast spread of COVID-19 has led to the use of certain technologies in a rapid and unusual manner. E-learning and home-office, for example, have increased the number of users of certain platforms such as Zoom and Microsoft Team as well as other video conferencing softwares. This sudden surge of users has created an environment favorable to the spread of cyber attacks.

In this work, we leverage information and intelligence covering different threats targeting various countries shared on AlienVault Open Threat Exchange (OTX). OTX is one of the largest platforms used to share cyber threats. By the time of our study, this platform contained 155K shared threats and 160K global users from 144 different countries. We explore different trends and patterns related to specific countries and malware families. We discuss campaign (mass) and targeted attacks, explore clusters of countries with the same characteristics, and analyze spatial-temporal trends of these threats and their spreading patterns across countries/organizations. In addition, analyze in depth the period of COVID-19 and investigate the most impacting threats.

This work attempts to answer several questions such as:

• What are the most targeted countries and common used malware families?
• How these attacks spread between countries?
• What are the main differences between the pre-covid and covid era cyberspace?

This type of analysis would help organizations better understand and anticipate threats. Integrating this information would help them understand the different techniques cybercriminals use against them based on the different profiles established. In addition, the more knowledge organizations have about the threats in the covid era, the better they can strengthen their defenses in the post-covid era.

The present paper is structured as follows: Next section provides a review of the related work to this study. Section [V] presents an exploratory analysis of the cyber attacks. Section [III] is a presentation of the data set used. In section [V] we identify countries clusters. Finally, in section [VI] we analyse the extent to which cyber threats trend have been affected by the COVID-19 outbreak and sanitary measures imposed by governments. Section [VII] concludes the paper.

II. RELATED WORK

Cyber attacks targeting industrial, companies and governmental organizations have become widespread and several attacks have made headlines in the last decade [3]. Recent cyber attacks have demonstrated the growing evolution of
security incidents and the immense damage they cause: loss of intellectual property, productivity, money and reputation [4] [5]. Security professionals are increasingly willing to share information about the current threats and attacks they face. This information sharing appears to be a promising form of early warning [6], which can be used to take preventive measures to protect information systems. It is not surprising that both researchers and practitioners have taken the initiative to create methods and build tools that would allow the automated exchange of security information and use it to increase the level of protection and threat anticipation.

Cyber Threat Intelligence (CTI) has become a hot topic and researchers have worked on analyzing sharing platforms content. Abu et al [7] identified several issues for threat data quality on sharing platform. The study includes a survey of common language and tools available in CTI. Sauerwein et al. [8] proposed an exploratory study of software vendors of threat intelligence sharing platforms. The study identified a growing interest towards threat intelligence sharing and a lack on the consistency of shared threats. Gschwandtner et al. [9] proposed a framework for integrating threat intelligence within existing information systems. They evaluated the framework and its reliability with information security practitioners by studying its ability to generate a vulnerability report, prioritizing critical vulnerabilities and related mitigation activities.

Few studies explored the spatio-temporal dependencies of cyber threats. Dowling et al. [10] analyzed temporal and spatial large-scale cyber attacks. The paper demonstrate a favorable correlation between the recorded activity and the established probability. On the other hand Du et al. [11] proposed a work flow for identifying attack sources belonging to the same coordinated attack groups.

Our work generalizes the approach in [10], [11] by constructing graphs for each spatial source of attacks (IPs) over time, in order to uncover the general threat patterns followed by attackers, and to predict incidents rates at the country level.

Cyber Security in the Age of COVID-19: The COVID-19 crisis is associated with drastic, unprecedented changes in people’s daily live, especially related to the use of multimedia (E-learning, home office...). This can lead to new crime opportunities [12]. Online fraud and cyber-attacks have considerably increased during the COVID-19 pandemic. Cyber-threats rates have been particularly high during the periods were the lockdown policies were the strictest [13]. Also during the pandemic, cyber criminals have used Advanced Persistent Threat (APT) targeted vulnerable user and systems taking advantage of the new domestic use of technology [14] [15].

III. DATA SET

A. Data Collection

Open Threat Exchange (OTX) is a free to use crowd-sourced computer-security platform. It is the world largest platform of this kind with more than 160K participants in 144 countries. This data set contains incidents that targeted particular industries and organizations in different regions of the world. We developed our own web crawler and stored all the incidents as raw HTML pages. We were able to extract over than 13000 unique security events occurred between 2015 and Sep. 2020.

B. Data Preprocessing

In this section we will briefly describe how we reduced scraped HTML files into a structured form containing the relevant information about attacks. We used the semi structured form of HTML and the tags specific to each field to be able to find more easily the information we needed on each web page. The main information we have extracted about the incidents are: incident description, incident title, targeted country, date of the incident and the adversary responsible of the attack. As our goal is to predict security incidents’ rates over governments, we need a geographical view outlining the evolution and transition of attacks from one country/state to another, which we find in this dataset. The parsed pages containing shared threats as entered by the stakeholders need to be processed since countries names are usually misspelled. In addition, since our approach is geographically driven, we need to unify countries name spelling. To this end, we the Levenshtein distance [16] to compare two strings as given by Equation (1)

$$\\text{lev}_{a,b}(i,j) = \begin{cases} \max(i, j) & \text{if } min(i, j) = 0 \\
\text{lev}_{a,b}(i-1, j) + 1 & \text{if } a \neq b, i > 0 \\
\text{lev}_{a,b}(i, j-1) + 1 & \text{if } a \neq b, j > 0 \\
\text{lev}_{a,b}(i-1, j-1) + 1_{(a \neq b)} & \text{otherwise.}
\end{cases}$$

This distance measures the difference between two strings by examining the number of changes (i.e. insertions, deletions or substitutions) made to a character to change one word into another. This approach is widely used in text mining and Natural Language Processing fields [17]. We used a dictionary containing all the country names written correctly and use the algorithm above to obtain a data set with homogeneous and correct country names.

IV. ATTACKS EXPLORATORY ANALYSIS

In this section, we analyze the collected incidents data in order to gain insight into the underlying patterns such as which countries are most targeted, the frequency of attacks, and how these attacks spread from country to country.

A. Most Targeted Countries

We begin by aggregating the attacks reported for each country. That is, we aggregate the threats posted by country name and we count the number of incidents for each one. Fig. 1 shows a heatmap of the most attacked countries (dark color) to the less attacked countries. Also, we observe that the most targeted countries are, as excepted, USA, China and Russia alongside. We can conclude that attackers tend to target most powerful countries known as super power: USA, China, Russia. European Union (E.U) countries combined were hit by 31% of all the attacks. United States is subject to nearly 22.2% of the attacks. Furthermore, among 140 countries, only 17 attract 80% of the threats and 45 countries attract 99% of

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{heatmap.png}
\caption{Heatmap of the most attacked countries (dark color) to the less attacked countries.}
\end{figure}
it as shown by the cumulative distribution function in Figure 2.

![Heat map of the reported cyber incidents over countries (2016-2020)](image)

**Fig. 1.** Heat map of the reported cyber incidents over countries (2016-2020)

**B. Attacks Evolution**

In order to study the frequency of attacks between 2016 and 2020, we construct a time series of number of attacks. As shown in Fig. 3, we observe that the time series of the attacks is quite stationary except for the two peaks in March and August 2017, and slight increase in January and April 2019. The two spikes of 2017 could be explained by two major attacks, namely, WannaCry in May 2017 and the Apache Struts vulnerability in March 2017. As for the increase in 2019, this coincides with the Facebook user data leaks (which came almost exactly one year after the Cambridge Analytica scandal). Also, the big increase in 2020 could be highly related to the covid-19 pandemic and its governmental measures.

![Attacks cumulative percentage by countries](image)

**Fig. 2.** Attacks cumulative percentage by countries

In the same vein, looking at the most used malware families illustrated in the table, we observe that 2019 was characterized by ransomware attacks that are primarily motivated by financial gain. As for 2020 and with the pandemic, the attacks began to shift from financial gain to information seeking by using spyware to obtain sensitive information.

| Year | Top malwares                                      | Type                        |
|------|---------------------------------------------------|-----------------------------|
| 2019 | Emotet: trojan:win32/mokesped trojan:win64/turla  | Banking trojan              |
|      | Dridex: ransom:win32/wannacrypt                   | Ransomware                  |
|      | Dridex: trojan:win64/turla                        | Trojan Spy (espionage)      |
| 2020 | Emotet: trojan:win32/qakbot                        | Banking trojan              |
|      | Phishing: w97m/downldr.ie.gen/eldorado            | Phishing                    |
|      | Backdoor: php/webshell                            | Backdoor                    |
|      | trojan:win32/qakbot                               | Backdoor Trojan             |
| 2021 | Cobalt Strike: fp539598-vbs/loveletter.bt         | Penetration tool            |
|      | revil: win32:dangeroussig                         | Mass-mailing worm           |
|      | win.packed.agentino-9863792-0                      | Trojan                      |
|      | win32:dangeroussig                               | Trojan                      |

**C. Attacks Spreading Pattern**

In this section, we model the spreading of cyber attacks using transition probability matrix to generate transition graphs. We assess the relationship between countries by determining the probability of transition of the same attack from a country to another, then, we identify ways attacks spread geographically.

1) **Most Targeted Tuples**: Here we try to identify the country pairs that often appear in the same attack campaigns. Thus the Figure 4 shows that it is generally neighbouring countries that are often affected by the same attacks. However, we also see that the United States is also linked to several countries. This is explained by the fact that it is by far the most attacked country as seen in Section IV-A.

2) **Attacks’ Transition Graph**: An attack can be characterized by 3 major elements: targeted country, adversary, and attack type. Our objective is to analyze for each type of attack the geographical propagation behavior. Therefore, we only take into account two characteristics: the type of attack and the country being attacked. Graphs are generated by aggregating data by type of incident. We then calculate the number of occurrences of countries in the same attack. The
Concerned by wilder campaigns such as spamming campaigns or probing (i.e., broad attacks campaigns).
its cluster and the USA and Canada appeared in the same
cluster as the great powers of the EU. Also the countries of
Eastern Europe are grouped together in a same cluster. The
same is true for Latin American countries. These results add
more evidences to our hypothesis that it is possible to highlight
a geographical pattern of cyber attacks.

Fig. 6. Countries Clustering using Spectral Clustering

B. Threats Time Series correlation analysis

The last step of the exploratory analysis is to investigate
whether there is a pattern concerning the time factor in the
propagation of attacks. For this reason we have looked to
the correlation between the time series of attacks of different
countries by computing the Pearson Correlation Coefficient.
The more the two time series are correlated, the closer the
Pearson value will be to 1 or -1, and the less they will
be, the closer the value will be to 0. Figure 7a shows the
heat map of the absolute value of Person correlation for all
countries listed. We can see that most of them are not very
correlated. And those correlated belong to the same cluster. On
the other hand, Figure 7b shows that by using a 7 days time
lag, correlation between the attacks is on clearly increasing
for most of the countries. This indicates that in addition to the
geographical link, there is also a considerable link between
countries concerning the occurrence of security incidents with
a time lag of 7 days.

Fig. 7. Comparison of point-wise correlation and cross-correlation

VI. COVID-19 CASE STUDY

Since the beginning of the covid-19 pandemic in late 2019
and with the resulted curfew and lockdown policies, many
activities moved to operate online. This led to a dramatic
increase in cyber attacks targeting both individuals and or-
ganizations [13]. In this section we study the threats shared
between January 2020 and June 2021 and look at different
aspects that characterized the covid-19 era.

A. Shared threats during Covid-19

With the pandemic, governments imposed many sanitary
measures to limit the spread of the virus or begin the pro-
duction of the vaccine. As Fig. 8 illustrates, we observe an
increase in cyber threats after the launch of the vaccine clinical
trials, after the vaccination campaign have begun and recently
the increase could be attributed to the anti-lockdown protests.
This shows that covid-19 and its different events and measures
had an impact on the increase of cyber attacks around the
world.

Fig. 8. Covid related events and OTX shared threats between Jan 2020 and
Aug 2021

B. Attacks targeting vaccine development

Since the launch of the research about the vaccine develop-
ment in many countries, particularly in the USA, Germany,
UK, etc. threats witnessed an increase. This increase was
mainly attributed to APT29 group targeting mostly countries
involved in vaccine development in order to spy on the pro-
duction process and breach development data. In this section,
we focus on APT29, analyze its related attack vectors and
characteristics. MITRE ATT&CK attributed several attacks ids
as techniques used by APT29. We used these techniques
ids to filter only shared threats related to APT29. Doing so,
we look for top malware families used by APT29, affected
industries and targeted countries. Table II shows the top 5
malware families which are mostly penetration and spying
malwares. In addition, government and manufacturing featured
as the most targeted sectors as they are related directly to the
vaccine development. As for the top targeted countries, we
found that these countries are among the first to begin vaccine
research and production.

5https://www.ncsc.gov.uk/news/advisory-apt29-targets-covid-19-vaccine-
development
6https://attack.mitre.org/groups/G0016/
Moreover these countries are being targeted usually together by the same attacks, as shown by the high probabilities of transition in Figure [9]. We can see for example that 47% of the cases where UK (Astrazeneca) have been targeted by APT29, USA (Pfizer, Moderna and Jansen) have been targeted too. Also in 33% of the cases Germany(Pfizer) is targeted when UK is. Also the fact that few countries have been targeted shows that this attacks are targeted attacks and not broad campaign.

![Fig. 9. Propagation of APT29 related attacks during COVID-19 Pandemic](image)

**VII. CONCLUSION**

This work presented an exploratory data analysis performed on 155k shared threats including 10k cyber threat related to COVID-19. The investigation of this data has highlighted the existence of a spatio-temporal trend of cyber threats between countries and that they can be classified into clusters. It also showed that there is an evolution over years on top malware types used. Our study showed that abnormal event relative to COVID-19 appear to have a loose correlation with the increase of cyber-attack campaigns. Our research presents opportunity for further investigations. This research has shown what can best be described as a loose direct relationship between COVID-19 related events and cyber-attacks. Further research should investigate this phenomenon and outline whether a predictive model can be used to confirm this relationships and patterns.

**TABLE II**

**Top 5 indicators featured in APT29 and related attacks**

| Category | Top 5 |
|----------|-------|
| Malware  | Cobalt Strike (Penetration tool) | TrickBot (Stealing trojan) | XMRig (cryptominer - trojan-ransom) | Ryuk (ransomware) | Agent Tesla - S0331 (spyware) |
| Industry | Government | Finance | Manufacturing | Defense | Technology |
| Country ranking | United States of America | Germany | Republic of Korea | India | China and United Kingdom |
