Abstract
Alopecia areata (AA) is the most common immune-mediated hair loss disorder with a life-time prevalence of 2%. The pathogenesis of AA is not completely understood, but interferon gamma (INF-\(\gamma\)) and Janus kinases (JAK) may play a key role. Here, we present a case involving a male patient with psoriasis and psoriatic arthritis, who exhibited a rapid hair loss, diagnosed as AA, during ciclosporin treatment. As ciclosporin was unable to control his psoriasis, the treatment was changed to methotrexate injections, but the hair loss progressed into alopecia universalis. During treatment with the oral JAK inhibitor tofacitinib, the patient presented an almost complete hair remission on the scalp and partly on the eyebrows, eyelashes, beard, and chest. Furthermore, the patient experienced no joint complaints and his psoriasis was improved. Based on these findings, JAK inhibitors may be an optional treatment in complicated cases involving both rheumatological and dermatological diseases.
Introduction

Alopecia areata (AA) is an immune-mediated hair loss disorder with a lifetime prevalence of 2% [1]. AA is a predominantly type 1-driven inflammation with interferon-gamma stimulating Janus kinase (JAK) leading to activation of the JAK STAT pathway [2]. Likewise, type 1 inflammation is important in the initiation of psoriasis and psoriatic arthritis, but Th17 cytokines have been shown to play a dominant role in the chronic phase of psoriasis [3].

Tofacitinib, a selective JAK inhibitor suppressing preferentially JAK1 and JAK3, is approved for psoriatic arthritis, rheumatoid arthritis, and ulcerative colitis, but has also been shown effective in several other dermatological diseases [2].

Here, we present a case including a patient with psoriasis, psoriatic arthritis, and AA who achieved improvement in all diseases after treatment with tofacitinib.

Case Report

A 49-year-old man with a history of psoriatic arthritis had been seen at our department for several years for treatment of severe psoriasis. Due to gastrointestinal side effects of orally administered methotrexate 15 mg per week, his psoriasis was treated with ciclosporin 100 mg twice daily from January 2014 until January 2018 with efficient results. Since 2003 he had been treated with salazopyrine 1 g twice daily for psoriatic arthritis and had no joint complaints.

At the end of 2015, the patient exhibited a rapid hair loss located on the scalp and AA was diagnosed. This progressed into alopecia totalis over 3 years. From October 2017 to February 2018, his AA was treated with diphencyprone (DCP), initially 2% down-titrated to 0.001% twice monthly; however, the effect was discrete with only minor hair regrowth in the occipital area.

In January 2018, his psoriasis could no longer be controlled with ciclosporin, and subcutaneous methotrexate 15 mg per week was initiated. After 3 months, the hair loss progressed and involved the scalp, eyebrows, eyelashes, beard, and chest and he was diagnosed with alopecia universalis (AU) (Fig. 1a, b, Fig. 2a, b). Additionally, he had no improvement in psoriasis, and in May 2018 tofacitinib 5 mg twice daily was initiated as a potential treatment for psoriasis, psoriatic arthritis, and AU. After 3 months of treatment, a moderate remission in hair regrowth was observed, the psoriasis had almost cleared and the patient had no joint complaints, thus treatment with salazopyrine was paused.

In January 2019, an impressive hair regrowth was seen on the scalp, beard, eyebrows, and a partly remission of the eyelashes (Fig. 1c, d). Furthermore, the patient had no relapse in psoriatic arthritis and only minor psoriatic plaques were seen (Fig. 2c, d).

Discussion

This is a rather unusual case, as AA development occurred while the patient was treated with ciclosporin, which has shown to be effective in up to 57% of patients with AA [4].

Treatment of AA is challenging, with first-line treatment including DCP and topical steroids. In a systematic review and meta-analysis, methotrexate was found to be effective for the treatment of AA, especially when given in combination with topical steroids [5]. However, methotrexate is not well tolerated in all patients, and as seen in the current case, not always
with acceptable effect on AA/AU. Among other systemic treatments for AA, JAK inhibitors have been described as a new promising therapy. In a recent clinical trial, almost 40% of patients with AA experienced complete regrowth after treatment with tofacitinib [6].

To the best of our knowledge, this is the first case report describing a patient with multiple diseases including psoriasis, psoriatic arthritis, and AU who is successfully treated with tofacitinib.

Oral JAK inhibitors have similar safety profiles as other immunosuppressive drugs, and could be considered in cases with refractory concomitant diseases where JAK inhibitors can be effective for both dermatological and rheumatological conditions.

**Statement of Ethics**

The research was conducted ethically in accordance with the World Medical Association Declaration of Helsinki. The subject has given his written informed consent to publish his case (including the images).

**Conflict of Interest Statement**

Dr. Todberg has served as investigator for Novartis and LEO Pharma. Dr. Loft has been an honorary speaker for Eli Lilly. Dr. Zachariae has consulting relationships and/or is an investigator and/or received grants or honoraria from Eli Lilly and Company, Janssen Cilag, Novartis Pharmaceutical Corp., AbbVie, Takeda, Amgen, MSD, LEO Pharmaceuticals, Boehringer-Ingelheim, Almirall, and Regeneron.

**Funding Sources**

No funding was received.

**Author Contributions**

C.Z. was the physician who had several consultations with the patient. C.Z., N.D.L., and T.T contributed to the preparation of the manuscript.
