ABSTRACT

Introduction: It is known that actual values of thickness of epidermis of the skin and its variations with body site, age and sex are important in fields of medical and biological research. The variations in skin reaction to certain stimuli could be due to biological factors such as epidermal thickness, dermal thickness, distribution of epidermal appendages etc.

Aims: Aim of the present study was to establish variations in the number of different components of skin in human cadavers.

Material and Methods: Skin was procured from the sole of six freshly formalin-fixed human cadavers. Out of these three were males and three were females. The age of male and female cadavers ranged between 60 to 70 years (mean age 67 years). Skin samples measuring 1cm (L) X 0.5cm (B) were taken from the centre of the sole. Tissue was preserved in 10% formaldehyde for 48 hours and further histological techniques were followed.

Results: In females thickness of the epidermis (Edp) of were observed (866.07±22.20µm), the thickness of stratum corneum (470.43±21.68µm), layers of stratum spinosum and stratum granulosum were 3, number of rete pegs (11.41±1.01), depth of rete pegs (62.89±5.96µm), the thickness of the papillary dermis and reticular dermis were (182.23±14.60µm) and (871.20±16.93µm) respectively. Whereas In males thickness of the epidermis (Edp) were observed (562.10±24.91µm), the thickness of stratum corneum was (484.36±49.21µm), layers of stratum spinosum and stratum granulosum were 3 and 1 respectively, the number of rete pegs 10.81±1.92, depth of rete pegs (103.04±18.95µm), thicknesses of the papillary dermis and reticular dermis was (100.10±21.68µm) and (829.76±186.50µm) respectively.

Conclusion: Females showed thicker epidermis as well as dermis in comparison to males. Females had more number rete pegs but these are shallower than males.

Key Words: Sole, Epidermis, Stratum corneum, Rete pegs, Thickness, Dermis

INTRODUCTION

Skin is one of the visible and largest organ of the body and unsheathes all other organ.¹ It protects against various external physical, chemical, and biological assailants, as well as prevents excess water loss from body.² Variations in skin reaction depend upon its epidermal and dermal thickness, and distribution of epidermal appendages.³ Accurate values of thickness of epidermis of the skin and its variation with body site, sex and age are important in the fields of medical and biological research.

A wide variety of agents encountered in the workplace may cause irritation, injury, sensitization, infection or discoloration in the skin of the exposed worker. Some agents even can induce cancerous changes in the skin.⁴ Variations in thickness of the skin can affect the absorption of ionizing radiations. This is particularly important in the nuclear power industry where the dose to the basal layer of skin (deepest epidermal layer) can set a limit on time, during which operators are allowed to perform work. Diffusion of a radioactively labelled compound occurs through the epidermis and dermis into the blood vascular system of living subjects. Hence, it is essential to have values of epidermal thickness so that measurements can be interpreted in terms of dose to the basal layer. Protective measures against exposure of radioactive components are dependent on the skin thickness of various exposed parts. In absence of quantitative data, some thick parts may be unnecessarily protected or vice versa.⁵
Several studies have been performed regarding various parameters of normal skin, both from cadaveric skin and from living healthy volunteers.\cite{3, 5, 6, 7} Data is also available stating the histological changes in the skin with advancing age\cite{8, 9, 10} but a clear lacuna is seen in the documentation of differences in the histological features of the skin of the sole of human male and female. Therefore, the present study was carried out to formulate a basic background of differences that can set a standard to compare pathological and chronological changes.

**MATERIAL AND METHODS**

The present observational study was done in the Department of Anatomy, King George Medical University, Lucknow from August 2017 to September 2018. Ethical clearance was obtained from the Institutional Ethics Committee with IEC approval no.763/Ethics/R.Cell-18. For the present study, the skin was procured from the sole of six freshly embalmed human cadavers. Out of these three were males and three were females. The age of the male and female cadavers ranged between 60 to 70 years (mean age 67 years). Skin samples measuring 1 cm (L) X 0.5 cm (B) were taken from the centre of the sole. The tissue was preserved in 10% formaldehyde for 48 hours.

Fixed tissue specimens were dehydrated through increasing concentrations (30%, 50%, 70%, 90% and absolute) of ethanol. After clearing the tissue in xylene, embedding was done in paraffin wax. 5 µm thick sections were cut using a rotary microtome. The whole thickness of the tissue was sectioned. Three regions, each containing 3 sections were chosen at the interval of 20 sections. Thus, for each site of each cadaver 3 slides were prepared. Hence, 3 slides were containing a total of 9 sections of each tissue from each cadaver. Slides were stained by Haematoxylin [Harris’s] and Eosin stain. Each stained section was observed for 3 different fields thus for each cadaver 27 observations were obtained.

Following 8 quantitative parameters were observed for each slide;

1. The thickness of epidermis at dermal papilla (Edp)
2. The thickness of the stratum corneum (Tsc)
3. Number of layers of stratum spinosum at dermal papilla (ss)
4. Number of layers of stratum granulosum at dermal papilla (sg)
5. Depth of rete pegs (Drp)
6. Number of rete pegs (rp)
7. The thickness of the papillary dermis (Tpd)
8. The thickness of the reticular dermis (Trd)

The thickness of the above-mentioned parameters was measured with the help of ERMA’s micrometre. The value of each parameter in the micrometre was entered into a word excel sheet. For each parameter, 9 values were taken and the mean value was calculated. The values were represented in Number and Mean±SD. The mean value of each parameter was compared for gender-wise changes by using the student t-test and the Mann-Whitney test. p-value less than 0.01 was considered highly significant. The statistical analysis was done using SPSS (Statistical Package for Social Sciences) Version 21.0 statistical Analysis Software. The microphotography was done with the help of a device incorporated with software easy capture U S B 2.0 high-quality video and audio.

**RESULTS**

**Epidermis:**
The thickness of the epidermis at the dermal papilla of females was significantly higher as compared to males. The stratum corneum of the male sole was thicker as compared to females. The ratio of the thickness of epidermis at dermal papilla and stratum corneum was found to be higher among males as compared to females. Female skin showed more cell layers in stratum spinosum and stratum granulosum. These values were statistically significant also. In none of the specimens, stratum lucidum was observed. (Table 1, Fig 1.1,1,2)

**Dermoepidermal Junction:**
The number of rete pegs was significantly higher in the female sole as compared to males. As far as depth of rete pegs was concerned, in the female sole, these were significantly much shallower than males. (Table1)

**Dermis:**
The thickness of the Papillary dermis, as well as the reticular dermis of female planter skin, is higher as compared to males. Statistically significant values were observed for the higher thickness of the papillary dermis of the female sole. (Table 1; Fig 1.1,1,2)

**DISCUSSION**

The skin of the sole has the highest coefficient of friction as compared to the dorsum of the hand, anterior and posterior side of the forearm, middle anterior and posterior leg.\cite{11} It has been also shown that frictional properties can reflect the chemical and physical properties of the skin surface and thus depends on the physiological variations and pathological conditions of the skin.\cite{12}

In the present study thickness of epidermis at dermal papilla, layers of stratum spinosum and stratum granulosum of the non-friction site of the sole was significantly higher in females. Thickness of stratum corneum, SC/Edp ratio (propor-
tion of stratum corneum to whole thickness) was less than male. It can be appreciated that a higher number of layers or number of keratinocytes in stratum spinosum and granulosum resulted in greater thickness of epidermis in females. Also, in females greater number of rete pegs could have been responsible for contributing more basal keratinocytes and hence greater thickness of the epidermis. Relatively, the contribution of stratum corneum in total epidermal thickness was greater in males. In males, there was a greater depth of rete peg suggesting better interlocking to avoid greater frictional forces. In contrast, the thickness of both papillary, as well as reticular dermis, was more in females than males. So, the disparity in thickness of epidermis and dermis between genders suggest some regulation which is affected more than by mere its function (Table 1).

It is observed that collagen density and packing of fibrils in the dermis is influenced by age as well as sex. With increasing age, skin collagen decreases more rapidly than skin thickness so collagen density decreases. Thickness of the dermis is proportional to the collagen content and collagen density is less in females of all ages. Probably this could explain the reason for the greater thickness of female dermis than males in the present study.

Very little information on the microscopic topography of normal skin is available. Lee and Hwang reported the thickness of epidermis of palm and sole in the Korean population in the range of 601-637 µm. Egawa M et al., found the thickness of stratum corneum of palm 173 µm which is lesser than the thickness of stratum corneum of the palm of females but greater than males in the present study. These reports highlight the racial variations of skin thickness and suggest the need to create a reference model for quantitative characteristics of healthy skin from various sites in different populations.

Gender differences in the various parameters of skin could be attributed to estrogen. Recently estrogen receptors are demonstrated in the skin of mice. Shuster S et al., (1975) observed that the thickness of skin decreases linearly in males as early as, at the age of 20 in contrast it remains constant in females till 50 years and then it decreases. Waller JM et al., (2005) stated that the thickness of the epidermis decreases about 6.4% per decade on average whereas in postmenopausal women thickness decreases at a much higher rate than men. McCallion Ret al., (1993) observed that the thickness of the dermis decreases up to 20% in both males and females. Whereas de Rigal J (1989) mentioned in his study that thickness of dermis of sun unexposed sites decreases after 80 years.

During weight-bearing activities, the feet are exposed to large forces, particularly in dynamic activity such as walking to normal rollover during the stance phase of gait. Suprapapillary thickness of the epidermis, layers of stratum spinosum and stratum granulosum of the non-friction area of sole were statistically. The pressure under the plantar surface during walking varies per foot area because of various factors related higher in females than in males (table1). Whereas the thickness of the stratum corneum was higher in males. The number of rete peg was more in females in contrast to the depth of rete pegs which was more in males and was statistically significant too (table 1). The thickness of papillary and reticular dermis was higher in females than males. Igarashi T et al., (2005) reported in their article the thickness of epidermis of sole 1.6mm which was greater than the thickness of the epidermis (0.714±0.155mm) at the dermal papilla of the present study.

Even though subjects from both sexes belonged to the same age group, clear and statistically significant histological differences were observed in the skin of the sole. Females showed thicker epidermis and dermis in comparison to males. Females had more number rete pegs but these are shallower than males.

**CONCLUSION**

Females showed thicker epidermis as well as dermis in comparison to males. The higher number of layers or number

**Table 1: Gender wise comparison of various skin parameters from sole Region**

| Parameter                        | Female (n=27)          | Male (n=27)          | Statistical significance |
|----------------------------------|------------------------|----------------------|-------------------------|
|                                 | Mean      | SD       | Mean      | SD       | ‘t’/Z  | 'p'    |
| Thickness of epidermis (Epi)     | 866.07    | 22.20    | 562.10    | 24.91    | 47.331 | <0.001 |
| Thickness of stratum corneum(sc)| 470.43    | 21.68    | 484.36    | 49.27    | -1.345 | 0.185  |
| Edp:sc                           | 0.543     | 0.012    | 0.861     | 0.074    | -22.080| <0.001 |
| Layers of stratum spinoum(ss)    | 3.48 (3.00)| 0.51    | 2.44 (3.00)| 0.64    | -5.035 | <0.001 |
| Layers of stratum granulosum(sg)*| 3.00 (3.00)| 0.88    | 1.67      | 0.48     | -5.134 | <0.001 |
| Number of rete pegs              | 11.41     | 1.01     | 10.81     | 1.92     | 1.48   | 0.162  |
| Depth of rete pegs               | 62.89     | 5.96     | 103.04    | 18.95    | -10.499| <0.001 |
| Thickness of papillary dermis    | 182.23    | 14.60    | 100.10    | 21.68    | 16.330 | <0.001 |
| Thickness of reticular dermis    | 871.20    | 16.93    | 829.76    | 186.50   | 1.150  | 0.255  |
of keratinocytes in stratum spinosum as well as in stratum granulosum resulted in greater thickness of epidermis in females. In females, the greater number of rete pegs as compared to males could have been responsible for contributing more basal keratinocytes and hence greater thickness of the epidermis.

ACKNOWLEDGEMENT

The authors acknowledge the head of the Department of Anatomy, King George Medical University, Lucknow and the immense help received from the scholars whose articles are cited and included in references of this manuscript. The authors are also grateful to authors/editors/publishers of all those articles, journals and books from where the literature for this article has been reviewed and discussed.

Conflict of interest: There is no conflict of interest.

Source of funding: Nil.

Author’s contribution: All authors contribute to dissection, slide preparations and compiling this observational study.
