We study the $B \to \phi K_S$ and $B \to \eta' K_S$ decays in MSSM by calculating hadronic matrix elements of operators with QCD factorization approach and including neutral Higgs boson (NHB) contributions. We calculate the Wilson coefficients of operators including the new operators which are induced by NHB penguins at LO using the MIA with double insertions. We calculate the hadronic matrix elements of the new operators for $B \to \phi K_S$ and $B \to \eta' K_S$. It is shown that the recent experimental results on the time-dependent CP asymmetries in $B \to \phi K_S$ and $B \to \eta' K_S$, $S_{\phi K}$ is negative and $S_{\eta' K}$ is positive, which can not be explained in SM, can be explained in MSSM if there are flavor non-diagonal squark mass matrix elements of 2nd and 3rd generations whose size satisfies all relevant constraints from known experiments ($B \to X_S \gamma, B_s \to \mu^+ \mu^-$, $B \to X_s \mu^+ \mu^-$, $B \to X_s g, \Delta M_s$, etc.). In particular, we find that one can explain the experimental results with a flavor non-diagonal mass insertion of chirality LL or LR or RR when $\alpha_s$ corrections of hadronic matrix elements of operators are included, in contrast with the claim in the literature. At the same time, the branching ratios for the two decays can also be in agreement with experimental measurements.

I. INTRODUCTION

The measurements of the time dependent CP asymmetry $S_{J/\psi K}$ in $B \to J/\psi K_S$ have established the presence of CP violation in neutral B meson decays and the measured value

$$S_{J/\psi K} = \sin(2\beta(J/\psi K_S))_{\text{world-ave}} = 0.734 \pm 0.054,$$

is in agreement with the prediction in the standard model (SM). Recently, various measurements of CP violation in B factory experiments have attracted much interest. Among them,$^{2,3}$

$$S_{\phi K_S} = -0.39 \pm 0.41, \text{ 2002 World -- average}$$
$$S_{\phi K_S} = -0.15 \pm 0.33, \text{ 2003 World -- average}$$

(2)

is especially interesting since it deviates greatly from the SM expectation

$$S_{\phi K_S} = \sin(2\beta(\phi K_S)) = \sin(2\beta(J/\psi K_S)) + O(\lambda^2)$$

(3)

where $\lambda \approx 0.2$ appears in Wolfenstein’s parameterization of the CKM matrix. Obviously, the impact of these experimental results on the validity of CKM and SM is currently statistically limited. However, they have attracted much interest in searching for new physics,$^{4,5,6,7,8}$ and it has been shown that the deviation can be understood without contradicting the smallness of the SUSY effect on $B \to J/\psi K_S$ in the minimal supersymmetric standard model (MSSM)$^{7,8}$.

Another experimental result, which is worth to notice, is of the time dependent CP asymmetry $S_{\eta' K_S}$ in $B \to \eta' K_S$,$^{9,10}$

$$S_{\eta' K_S} = 0.02 \pm 0.34 \pm 0.03 \text{  BaBar}$$
$$= 0.43 \pm 0.27 \pm 0.05 \text{  Belle}$$

(4)

which deviates sizably from the SM expectation. Although both the asymmetries $S_{\phi K}$ and $S_{\eta' K}$ are smaller than the SM value, $S_{\phi K}$ is negative and $S_{\eta' K}$ is positive. Because the quark subprocess $b \to ss \bar{s}$ contributes to both $B \to \phi K_S$ and $B \to \eta' K_S$ decays one should simultaneously explain the experimental data in a model with the same parameters. It has been done in Ref.$^{10}$ in a model- independent way in the supersymmetric (SUSY) framework. In Ref.$^{10}$ the analysis is carried out using the naive factorization to calculate hadronic matrix elements of operators and the neutral Higgs boson (NHB) contributions are not included. As we have shown in a letter$^8$ that both the branching ratio (Br) and CP asymmetry are significantly dependent of the $\alpha_s$ corrections of hadronic matrix elements and NHB contributions are important in MSSM with middle and large $\tan \beta$ (say, $>8$). In the paper we shall perform
a detailed analysis of $S_{\phi K_S}$ and $S_{\eta' K}$ as well as $\text{Br}$ in MSSM including NHB contributions and the $\alpha_s$ corrections of hadronic matrix elements.

We need to have new CP violation sources in addition to that of CKM matrix in order to explain the deviations of $S_{\phi K_S}$ and $S_{\eta' K}$ from SM. There are new sources of flavor and CP violation in MSSM. Besides the CKM matrix, the $6 \times 6$ squark mass matrices are generally not diagonal in flavor (generation) indices in the super-CKM basis in which superfields are rotated in such a way that the mass matrices of the quark field components of the superfields are diagonal. This rotation non-alignment in the quark and squark sectors can induce large flavor off-diagonal couplings such as the coupling of gluino to the quark and squark which belong to different generations. These couplings can be complex and consequently can induce CP violation in flavor changing neutral currents (FCNC). It is well-known that the effects of the primed counterparts of usual operators are suppressed by $m_s/m_b$ and consequently negligible in SM because they have the opposite chirality. However, in MSSM their effects can be significant, since the flavor non-diagonal squark mass matrix elements are free parameters which are only subjective to constraints from experiments.

For the $b \to s$ transition, besides the SM contribution, there are mainly two new contributions arising from the QCD and chromomagnetic penguins and neutral Higgs boson (NHB) penguins with the gluino and squark propagator in the loop in MSSM. The relevant Wilson coefficients at the $m_W$ scale have been calculated by using vertex mixing method in Ref.\cite{12}. There is the another method, "mass insertion approximation" (MIA) \cite{13}, which works in flavor diagonal gaugino couplings $q\bar{q}g$ and diagonal quark mass matrices with all the flavor changes rested on the off-diagonal sfermion propagators. The MIA can be obtained in VM through Taylor expansion of nearly degenerate squark masses $m_{\tilde{q}}$, around the common squark mass $m_{\tilde{q}}, m_{\tilde{q}}^2 \approx m_{\tilde{g}}^2 (1 + \Delta_i)$. Thus MIA can work well for nearly degenerate squark masses and, in general, its reliability can be checked only a posteriori. However, for its simplicity, it has been widely used as a model independent analysis to find the constraints on different off-diagonal parts of squark mass matrices from experiments\cite{14}. Therefore, we use MIA to calculate Wilson coefficients in the paper.

As it is shown that both $\text{Br}$ and CP asymmetries depend significantly on how to calculate hadronic matrix elements of local operators\cite{8}. Recently, two groups, Li et al.\cite{15, 16} and BBNS\cite{17, 18}, have made significant progress in calculating hadronic matrix elements of local operators relevant to charmless two-body nonleptonic decays of $B$ mesons in the PQCD framework. The key point to apply PQCD is to prove that the factorization, the separation of the short-distance dynamics and long-distance dynamics, can be performed for those hadronic matrix elements. It has been shown that in the heavy quark limit (i.e., $m_b \to \infty$) such a separation is indeed valid and hadronic matrix elements can be expanded in $\alpha_s$ such that the tree level (i.e., the $\alpha_s^0$ order) is the same as that in the naive factorization and the $\alpha_s$ corrections can be systematically calculated\cite{17}. Comparing with the naive factorization, to include the $\alpha_s$ correction decreases significantly the hadronic uncertainties. In particular, the matrix elements of the chromomagnetic-dipole operators $Q_{8_g}^{(1)}$ have large uncertainties in the naive factorization calculation which lead to the significant uncertainty of the time dependent CP asymmetry in SUSY models\cite{10}. The uncertainties are greatly decreased in BBNS approach\cite{18}. In the paper we shall use BBNS’s approach (QCD factorization) to calculate the hadronic matrix element of operators relevant to the decays $B \to \phi K_S, \eta' K_S$ up to the $\alpha_s$ order.

The experimental results, $S_{\phi K}$ is negative and $S_{\eta' K}$ is positive but smaller than 0.7, which implies that new CP violating physics affects $B \to \phi K_S$ in a dramatic way but gives $B \to \eta' K_S$ a relatively small effect, which has been thought to be problematic\cite{20}. To solve the problem, Khalil and Kou invoke to have operators with opposite chirality because the decay constant of $\eta'$ is sensitive to the chirality of the quarks and that of $\phi$ is independent of the chirality of the quarks, operators with opposite chirality give contributions with opposite signs to $B \to \eta' K_S$ but contributions with the same sign to $B \to \phi K_S$. In MSSM the $LL$ (LR) and $RR$ (RL) mass insertions give contributions to operators with opposite chirality respectively. It is shown in Ref.\cite{10} that (1) it is possible to explain the experimental results if having both the $LL$ and $RR$ (or $LR$ and $RL$) mass insertions simultaneously, and (2) it is impossible to explain the experimental results if having only the LL and/or LR (or RR and/or RL) insertions. The first claim is certainly valid in general. However, the second claim is of the consequence of using the naive factorization to calculate hadronic matrix elements of operators: Current-current operators contribute to $B \to \eta' K_S$ but not to $B \to \phi K_S$. Their effects are not significant in both the naive factorization approach and the QCD factorization approach. However, the $\alpha_s$ corrections of hadronic matrix elements of QCD penguin operators and chromomagnetic-dipole operators have significant effects and consequently make the claim (2) in Ref.\cite{10} not valid. We show in the paper that one can explain the experimental results, $S_{\phi K}$ is negative and $S_{\eta' K}$ is positive but smaller than 0.7, with a flavor non-diagonal mass insertion of any chirality when $\alpha_s$ corrections of hadronic matrix elements of operators are included. We show that in the case of $LL$ and $RR$ mass insertions the Higgs mediated contributions to $S_{\phi K}$ alone can provide a significant deviation from the SM in some region of parameters and a possible explanation of $S_{\eta' K}$ in $1\sigma$ experimental bounds in a very small region of parameters, satisfying all the relevant experimental constraints. When including all the SUSY contributions, there are regions of parameters larger than those in the case of including only the Higgs mediated contributions in which the theoretical predictions for $S_{\phi K}$ and $S_{\eta' K}$ are in agreement with the data in $1\sigma$ experimental bounds. In the case of $LR$ and $RL$ insertions a satisfied explanation can also be obtained. We

* The chargino contributions have been studied in Ref.\cite{11}.
show that the branching ratio of $B \to \eta' K_S$, which in SM with the naive factorization is smaller than the measured value, can be in agreement with data due to SUSY contributions in quite a large regions of parameters.

The paper is organised as follows. In section II we give the effective Hamiltonian responsible for the $b \to s$ transition in MSSM. We give the Wilson coefficients of operators including those induced by NHBs at LO in MIA with double insertions. In Section III we present the decay amplitudes and the CP asymmetries $S_{bK}$ and $S_{\eta'K}$. In particular, the hadronic matrix elements of NHB induced operators to the $\alpha$ insertions. In Section IV, we present the decay amplitudes and the CP asymmetries (gluon) fields strength.

In Ref. [22], which are non-negligible if the mixing between left-handed and right-handed sbottoms is large and results in quite a large regions of parameters.

Here $Q_i$ are quark and gluon operators and are given by

$$Q_1^p = \frac{\lambda^p_2}{\lambda^p_2} \sum_{q} \left( C_1 Q_1^p + C_2 Q_2^p + \sum_{i=3,..,16} \left[ C_i Q_i + C_i' Q_i' \right] \right),$$

$$Q_2^p = \frac{\lambda^p_2}{\lambda^p_2} \sum_{q} \left( C_1 Q_1^p + C_2 Q_2^p + \sum_{i=3,..,16} \left[ C_i Q_i + C_i' Q_i' \right] \right),$$

$$Q_3(5) = \frac{\lambda^p_2}{\lambda^p_2} \sum_{q} \left( C_1 Q_1^p + C_2 Q_2^p + \sum_{i=3,..,16} \left[ C_i Q_i + C_i' Q_i' \right] \right),$$

$$Q_4(6) = \frac{\lambda^p_2}{\lambda^p_2} \sum_{q} \left( C_1 Q_1^p + C_2 Q_2^p + \sum_{i=3,..,16} \left[ C_i Q_i + C_i' Q_i' \right] \right),$$

$$Q_7(9) = \frac{\lambda^p_2}{\lambda^p_2} \sum_{q} \left( C_1 Q_1^p + C_2 Q_2^p + \sum_{i=3,..,16} \left[ C_i Q_i + C_i' Q_i' \right] \right),$$

$$Q_{11}(13) = \frac{\lambda^p_2}{\lambda^p_2} \sum_{q} \left( C_1 Q_1^p + C_2 Q_2^p + \sum_{i=3,..,16} \left[ C_i Q_i + C_i' Q_i' \right] \right),$$

$$Q_{12}(14) = \frac{\lambda^p_2}{\lambda^p_2} \sum_{q} \left( C_1 Q_1^p + C_2 Q_2^p + \sum_{i=3,..,16} \left[ C_i Q_i + C_i' Q_i' \right] \right),$$

$$Q_{15} = \frac{\lambda^p_2}{\lambda^p_2} \sum_{q} \left( C_1 Q_1^p + C_2 Q_2^p + \sum_{i=3,..,16} \left[ C_i Q_i + C_i' Q_i' \right] \right),$$

$$Q_{16} = \frac{\lambda^p_2}{\lambda^p_2} \sum_{q} \left( C_1 Q_1^p + C_2 Q_2^p + \sum_{i=3,..,16} \left[ C_i Q_i + C_i' Q_i' \right] \right),$$

$$Q_{17} = \frac{\lambda^p_2}{\lambda^p_2} \sum_{q} \left( C_1 Q_1^p + C_2 Q_2^p + \sum_{i=3,..,16} \left[ C_i Q_i + C_i' Q_i' \right] \right),$$

$$Q_{18} = \frac{\lambda^p_2}{\lambda^p_2} \sum_{q} \left( C_1 Q_1^p + C_2 Q_2^p + \sum_{i=3,..,16} \left[ C_i Q_i + C_i' Q_i' \right] \right),$$

where $(\bar{q}_1 q_2)_{\gamma-(-)A} = \bar{q}_1 \gamma^\mu (1 \pm \gamma_5) q_2$, $(\bar{q}_1 q_2)_{\gamma-(-)A} = \bar{q}_1 (1 \pm \gamma_5) q_2$. $p = u, c, q = u, d, s, c, b$, $e_q$ is the electric charge number of q quark, $\lambda_\alpha$ is the color SU(3) Gell-Mann matrix, $\alpha$ and $\beta$ are color indices, and $F_{\mu\nu}$ ($G_{\mu\nu}$) are the photon (gluon) fields strength.

The primed operators, the counterpart of the unprimed operators, are obtained by replacing the chirality in the corresponding unprimed operators with opposite ones. We calculate the SUSY contributions due to gluino box and penguin diagrams to the relevant Wilson coefficients at the $m_W$ scale in MIA with double insertions, as investigated in Ref. [22], which are non-negligible if the mixing between left-handed and right-handed sbottoms is large and results are

$$C_3^{(t)} = -\frac{\alpha_s^2}{2\sqrt{2}} \frac{2}{G_F \lambda_1 m_\beta^2} \sum_{i=1}^{10} \left( \frac{1}{18} p_i(x) - \frac{1}{18} p_2(x) \right) \delta_{23}^{\text{LL}(RR)} + \delta_{23}^{\text{LR}(RR)} + \delta_{23}^{\text{LR}(RR)}.$$
where $\alpha_s$ and $\alpha_w$ are expansions to C results, the LR or RL insertion also generates the QCD penguin operators when one includes the double insertions.

For the $\gamma_i$, $\alpha_s$ results should be sufficient. The details of the running of these Wilson coefficients can be found in Ref. [23]. Differed from the single insertion, $\alpha_s$ results, the NLO renormalization group equations (RGEs) should be used. However for the $\gamma_i$, $\alpha_s$ results also generate the QCD penguin operators when one includes the double insertions.

For the processes we are interested in this paper, the Wilson coefficients should run to the scale of $O(m_b)$. $C_1 - C_{10}$ are expanded to $O(\alpha_s)$ and NLO renormalization group equations (RGEs) should be used. However for the $C_{8g}$ and $C_{7g}$, LO results should be sufficient. The details of the running of these Wilson coefficients can be found in Ref. [21]. The one loop anomalous dimension matrices of the NHB induced operators can be divided into two distangled groups [24].

$$\gamma^{(RL)} = \begin{pmatrix} Q_{11} & Q_{12} \\ Q_{12} & -6 & 2 \end{pmatrix}$$

with $C_{Q_{1,2}}$ as

$$C_{Q_1} = \frac{4}{3\lambda} \frac{g_s^2 m_w^2 m_t^2}{m_t^2} \frac{m_b m_t^2}{c_\beta^2} \delta_{23}^{dLL(RR)} \delta_{33}^{dLR(LR^*)}$$

$$C_{Q_2} = \frac{4}{3\lambda} \frac{g_s^2 m_w^2 m_t^2}{m_t^2} (r_p + \tan^2 \beta) \frac{m_b}{m_t^2} \delta_{23}^{dLL(RR)} \delta_{33}^{dLR(LR^*)}$$

where $r_s = \frac{m_t^2}{m_b^2}$, $r_p = \frac{m_t^2}{m_b^2}$, and $x = m_t^2/m_b^2$ with $m_t$ and $m_b$ being the common quark mass and gluino mass respectively. The one-loop functions in Eq. 4 are given in Appendix A. The parts of Wilson coefficients $C_{i}^{(q)}$ (i= 3,...,7,8, 8g) which are obtained by single insertion are the same as those in Ref. [23]. Differed from the single insertion results, the LR or RL insertion also generates the QCD penguin operators when one includes the double insertions.

The one loop anomalous dimension matrices of the NHB induced operators can be divided into two distangled groups [24].

$$\gamma^{(RL)} = \begin{pmatrix} Q_{11} & Q_{12} \\ Q_{12} & -6 & 2 \end{pmatrix}$$

The operator of $Q_{1,2}^{(q)}$ is defined as $Q_1 = \frac{2}{\pi x}[s(1+\gamma_6)b][\bar{b}][\bar{t}]$, $Q_2 = \frac{2}{\pi x}[s(1-\gamma_6)b][\bar{b}][\bar{t}]$, $Q_2 = \frac{2}{\pi x}[s(1-\gamma_6)b][\bar{b}][\bar{t}]$.
and

\[
\gamma^{(RR)} = \begin{bmatrix}
Q_{13} & Q_{14} & Q_{15} & Q_{16} \\
Q_{13} & -16 & 0 & 1/3 & -1 \\
Q_{14} & -6 & 2 & -1/2 & -7/6 \\
Q_{15} & 16 & -48 & 16/3 & 0 \\
Q_{16} & -24 & -56 & 6 & -38/3 \\
\end{bmatrix}
\]

Here and hereafter the factor, \( \frac{\alpha_s}{4\pi} \), is suppressed \( \text{i.e., the anomalous dimension matrix for } Q_{11,12} \) is \( \frac{\alpha_s}{4\pi} \gamma^{(RL)} \), etc. For \( Q'_i \) operators we have

\[
\gamma^{(LR)} = \gamma^{(RL)} \quad \text{and} \quad \gamma^{(LL)} = \gamma^{(RR)}.
\]

Because at present no NLO Wilson coefficients \( C_i^{(RL)} \), \( i=11,...,16 \), are available we use the LO running of them in the paper.

There is the mixing of the new operators induced by NHBs with the operators in SM. The leading order anomalous dimensions have been given in Refs. \[23, 24\]. We list those relevant to our calculations in the following. Defining

\[
O_i = \frac{g^2}{16\pi^2} Q_{12+i}, \quad i = 1, 2, 3, 4,
\]

one has

\[
\gamma^{(RD)} = \begin{bmatrix}
Q_{77} & Q_{88} \\
O_1 & -1/3 & 1 \\
O_2 & -1 & 0 \\
O_3 & 28/3 & -4 \\
O_4 & 20/3 & -8 \\
\end{bmatrix}
\]

The mixing of \( Q_{11,12} \) onto the QCD penguin operators is

\[
\gamma^{(MQ)} = \begin{bmatrix}
Q_3 & Q_4 & Q_5 & Q_6 \\
O_{11} & 1/9 & -1/3 & 1/9 & -1/3 \\
O_{12} & 0 & 0 & 0 & 0 \\
\end{bmatrix}
\]

For the mixing among the primed operators, we have

\[
\gamma^{(LD')} = \gamma^{(RD)} \quad \text{and} \quad \gamma^{(MQ')} = \gamma^{(MQ)}.
\]

The mixing of the new operators induced by NHBs with the operators in SM has non-negligible effects on the Wilson coefficients of the SM operators at the \( O(m_b) \) scale. In particular, the Wilson coefficient of the chromo-magnetic dipole operator \( C_{8g} \) at the \( O(m_b) \) scale, which has a large effect to \( S_{MK} (M = \phi, \eta' ) \), can significantly enhance due to the mixing. To see it explicitly we concentrate on the mixing of \( O_i \) (for its definition, see Eq. (12)) onto \( Q_{8g} \). Solving RGEs, we have

\[
C_{8g}(\mu) = \sum_{c=1,...,4} A(\mu_0)(\eta(\mu)\gamma_{cc}\gamma_{0\beta_0} - \eta(\mu)\gamma_{g8g}/2\beta_0) + C_{8g}(\mu_0)\eta(\gamma_{g8g}/2\beta_0),
\]

\[
A(\mu_0) = \sum_{a,b=1,...,4} \gamma_{ab}V^{a-1}V^b C_b(\mu_0)/(\gamma_{cc} - \gamma_{g8g})
\]

\[
\eta = \alpha_s(\mu_0)/\alpha_s(\mu),
\]

where \( V \) and \( \gamma_{aa} \) are given by

\[
V(\gamma^{(RR)} + 2\beta_0 I) V^{-1} = \text{diag}(\gamma_{11}, \gamma_{22}, \gamma_{33}, \gamma_{44}).
\]

with \( I \) being the 4 x 4 unit matrix. Using

\[
C_a(\mu_0) = C_1(\mu_0)\delta_a
\]

and Eq. (13), Eq. (16) reduces to

\[
C_{8g}(\mu) = 0.68C_{8g}(\mu_0) - 3.2C_{13}(\mu_0),
\]

where \( C_1(\mu_0) = \frac{\alpha_s}{4\pi} C_{13}(\mu_0) \) has been used.

In our numerical calculations we neglect the contributions of EW penguin operators \( Q_{7,..10} \) since they are small compared with those of other operators.
III. THE DECAY AMPLITUDE AND CP ASYMMETRY

We use the BBNS approach [17, 18] to calculate the hadronic matrix elements of operators. In the approach the hadronic matrix element of a operator in the heavy quark limit can be written as

\[ \langle MK_S|Q|B\rangle_f = \langle MK_S|Q|B\rangle_f [1 + \sum r_n \alpha^n_s], \]  

where \( \langle MK_S|Q|B\rangle_f \) indicates the naive factorization result and \( M = \phi, \eta' \). The second term in the square bracket indicates higher order \( \alpha_s \) corrections to the matrix elements [13]. We calculate the hadronic matrix elements to the \( \alpha_s \) order in the paper. In order to see explicitly the effects of new operators in the MSSM we divide the decay amplitude into three parts. One has the same form as that in SM, the second is for primed counterparts of the SM operators, and the third is new which comes from the contributions of Higgs penguin induced operators. That is, we can write the decay amplitude for \( B \to MK_S \) as

\[ A(B \to MK_S) = \frac{G_F}{\sqrt{2}} A \]

\[ A = A^o + A^{o'} + A^n, \]  

\[ A^{o'} = \begin{cases} 
A^o(C_i \to C'_i) & \text{for } B \to \phi K_S \\
A^n(C_i \to -C'_i) & \text{for } B \to \eta' K_S 
\end{cases} \]

(23)

(24)

(25)

(26)

(27)

(28)

Here \( \lambda_{MK} \) is defined as

\[ \lambda_{MK} = \left( \frac{q}{p} \right)_B \frac{A(B \to MK_S)}{A(\overline{B} \to MK_S)}. \]

(29)

(30)

\[ A^n \] for \( B_d^0 \to \phi K_S \), to the \( \alpha_s \) order, in the heavy quark limit is given as \[ 10 \]

\[ A^n = A^n(C_i) + A^n(C_i \to C'_i), \]

\[ A^n(C_i) = \langle \phi | \bar{s} \gamma_{\mu} s | 0 \rangle \langle K | \bar{q} \gamma_{\mu} q | B \rangle (-V_{tb} V^*_{ts}) \left[ a^2_{14} e_u^1 + \frac{m_s}{m_b} \left(-\frac{1}{2} a_{12} + \frac{4m_s}{m_b} a_{15} \right) \right]. \]

(30)
Here we have used the BBNS approach \[17, 18\] to calculate the hadronic matrix elements of operators. Expressions of $A$'s in Eq. (30) are

\[
a_{n\text{eu}} = \frac{C_F a_s}{4\pi} \frac{P_{n\text{eu}}}{N_c},
\]

\[
a_{12} = C_{12} + \frac{C_{11}}{N_c} \left[ 1 + \frac{C_F a_s}{4\pi} \left( -V_\phi - \frac{4\pi^2}{N_c} H_{K_{\phi}} \right) \right],
\]

\[
a_{15} = C_{15} + \frac{C_{16}}{N_c},
\]

(31)

with $P_{\phi,2}$ being

\[
P_{\phi,2} = -\frac{1}{2} C_{11} \left[ \frac{m_s}{m_b} \left( \frac{4}{3} \ln \frac{m_b}{\mu} - G_\phi(0) \right) + \left( \frac{4}{3} \ln \frac{m_b}{\mu} - G_\phi(1) \right) \right]
\]

\[
+ C_{13} \left[ -2 \ln \frac{m_b}{\mu} C_\phi^0 - G_\phi(1) \right] - 4 C_{15} \left[ \left( \frac{1}{2} - 2 \ln \frac{m_b}{\mu} \right) G_\phi^0 - G_\phi(1) \right]
\]

\[
- 8 C_{16} \left[ \left( \frac{m_s}{m_b} \right)^2 - 2 \ln \frac{m_b}{\mu} G_\phi(1) \right] - 8 C_{16} \left[ -2 \ln \frac{m_b}{\mu} G_\phi^0 - G_\phi(1) \right]
\]

(32)

where $s_c = m_c^2/m_b^2$ and

\[
G_\phi^0 = \int_0^1 \frac{dx}{x} \Phi_\phi(x), \quad GF(s, x) = \int_0^1 dt \ln [s - x t t],
\]

\[
GF_\phi(s) = \int_0^1 dx \frac{\Phi_\phi(x)}{x} \GF(s - i \epsilon x)
\]

(33)

with $\bar{x} = 1 - x$ and $\Phi_\phi(x) = 6x(1-x)$ in the asymptotic limit of the leading-twist distribution amplitude. In Eq. (33), the expressions of $V'$ and $H_{K_{\phi}}$ can be found in the Appendix B. In calculations we have set $m_{u,d} = 0$ and neglected the terms which are proportional to $m_c^2/m_b^2$ in Eq. (32). We have included only the leading twist contributions in Eq. (31). Here we have used the BBNS approach \[17, 18\] to calculate the hadronic matrix elements of operators.

### B. $B_d^0 \to \eta' K_S$

$A_0$ for $B \to \eta' K_S$, to the $a_0$ order, in the heavy quark limit has been given in Ref. [28] as

\[
A_0 = \sum_{p=u,c} V_{pb} \bar{V}_{ps} m_B^2 A_0^p
\]

\[
A_0^p = F^{B \to K} \left\{ f_{\eta'}^0 \left[ \delta_{a_0^p K}^2 (K_{\eta'}) + 2 (a_2 (K_{\eta'}) - a_5 (K_{\eta'})) - \mu_{\eta'}^s (a_6^0 (K_{\eta'}) - a_5^0 (K_{\eta'})) + \frac{1}{2} (-a_7 (K_{\eta'}) + a_9 (K_{\eta'})) \right] \right.
\]

\[
+ f_{\eta'}^0 \left[ a_3 (K_{\eta'}) + a_4^0 (K_{\eta'}) + a_5^0 (K_{\eta'}) + a_6^0 (K_{\eta'}) + \frac{1}{2} (-a_7 (K_{\eta'}) + a_9 (K_{\eta'})) \right] \right.
\]

\[
+ \frac{1}{2} \mu_{a_{10}^0 (K_{\eta'})} \left[ a_3 (K_{\eta'}) + a_4^0 (K_{\eta'}) + a_5^0 (K_{\eta'}) + a_6^0 (K_{\eta'}) + a_7^0 (K_{\eta'}) + a_8^0 (K_{\eta'}) - \frac{1}{2} \mu_{a_{10}^0 (K_{\eta'})} \right] \right\}
\]

(34)

where $F^{B \to M}$ ($M=\eta', K$) is a $B \to M$ form factor calculated at $q^2 = m_K^2$ or $m_{\eta'}^2 \approx 0$. The $a_0$'s in Eq. (34) have been given in Ref. [28] and are listed in Appendix B.

We calculate $A_0$ for $B \to \eta' K_S$, to the $a_0$ order, in the heavy quark limit and the result is

\[
A_0 = -V_{tb} \bar{V}_{ts} m_B^2 \left[ A_0^p (C_i) + A_0^p (C_i \to -C_i) \right],
\]

$A_0 (C_i) = F^{B \to K} \left\{ f_{\eta'}^0 \left[ -\mu_{a_{0}^p (K_{\eta'})} (a_6^0 (K_{\eta'}) - a_5^0 (K_{\eta'})) \right] + f_{\eta'}^0 \left[ a_3^0 (K_{\eta'}) - \mu_{a_{10}^0 (K_{\eta'})} (a_7^0 (K_{\eta'}) - a_8^0 (K_{\eta'})) - \frac{1}{2} a_{10}^0 (K_{\eta'}) \right] \right\}
\]

\[
+ F^{B \to \eta'} f_K \left[ a_3^0 (K_{\eta'}) + a_4^0 (K_{\eta'}) + a_5^0 (K_{\eta'}) + a_6^0 (K_{\eta'}) + a_7^0 (K_{\eta'}) + a_8^0 (K_{\eta'}) - \mu_{a_{10}^0 (K_{\eta'})} \right]
\]

\[
+ F^{B \to K} \left\{ \frac{m_d}{m_b} f_{\eta'} \left[ \frac{1}{2} \mu_{a_{11}^0 (K_{\eta'})} - \frac{1}{2} a_{11}^0 + \frac{1}{2} a_{13}^0 \right] + \frac{m_b}{m_b} f_{\eta'} \left[ \frac{1}{2} a_{12}^0 + \frac{1}{2} a_{14}^0 + \frac{1}{2} a_{13}^0 \right] \right\}
\]

(35)
and V_m calculations we set as

where decay constants \( f_{q'}^q, f_{q''}^q \) are defined in Appendix C, \( \mu_K = m_b R_K/2, \mu_{q'}^q = m_b R_{q'}^q \), and \( a_i^q \)'s and \( a_i \)'s are defined as

\[
a_1^q(M_1 M_2) = \frac{\alpha_s C_F}{4\pi N_c} P_{M_2,2}^n, \quad a_2^q(M_1 M_2) = \frac{\alpha_s C_F}{4\pi N_c} P_{M_2,3}^n,
\]

\[
a_8^q(M_1 M_2) = \frac{\alpha_{\text{em}} C_F}{9\pi N_c} P_{M_2,2}^{n, \text{EW}}, \quad a_9^q(M_1 M_2) = \frac{\alpha_{\text{em}} C_F}{9\pi N_c} P_{M_2,3}^{n, \text{EW}},
\]

\[
a_{11}(M_1 M_2) = C_{11} + \frac{C_{12}}{N_c},
\]

\[
a_{12}(M_1 M_2) = C_{12} + \frac{C_{11}}{N_c} \left[ 1 + \frac{C_F \alpha_s}{4\pi} \left( -V_{M_2}' - \frac{4\pi^2}{N_c} H_{M_1 M_2} \right) \right],
\]

\[
a_{13}(M_1 M_2) = C_{13} + \frac{C_{14}}{N_c} + \frac{C_{16}}{4\pi N_c} \left( -8V_{13} \right),
\]

\[
a_{14}(M_1 M_2) = C_{14} + \frac{C_{13}}{N_c} + \frac{2\alpha_s C_F}{4\pi N_c} (C_{13} V_{13} + C_{15} V_{15})
\]

where

\[
V_{13} = \int_0^1 du \phi_{M_2}(u) V_{S,2} + \int_0^1 du dv d\xi H_{S,3}
\]

\[
V_{15} = \int_0^1 du \phi_{M_2}(u) V_{T,2} - 4 \int_0^1 du dv d\xi H_{S,3}
\]

and \( V', H_{M_1 M_2} \) could be found in Appendix B. In Eqs. (36,37) \( V_{S,2} \) and \( V_{T,2} \) come from vertex contributions, \( P \)'s from penguin diagrams, and \( H_{S,3} \) from hard-scattering contributions, which will be shown in the following. In numerical calculations we set \( m_{u,d} = 0 \) so that the terms which are proportional \( m_q \) (q=u, d) in Eq. (36) are neglected.

- Vertex Contributions

The vertex contributions come from Fig. 1. In the calculations of vertex corrections we need to distinguish two diagrams with different topologies showed in Fig. 1 when we insert different operators. In the calculation of twist-3 contributions we find the infrared divergence cancels only if we include all four diagrams for each topology and use the asymptotic form of twist-3 distribution amplitude, i.e., \( \phi_p(x) = 1, \phi_s(x) = 6x(1-x) \), which can be combined into 

\[
\int f_P(x) \gamma_\mu^k_1 \gamma_\nu^k_2 \gamma_5 \Gamma^{k_2 k_1} \left[ 1 - 2 \right] .
\]

By a straightforward calculation, we obtain

\[
V_{S,2} = \int_0^1 du \left\{ 2 + 2 \ln u - 2 \bar{u} \left( \text{Li}_2 \left( 1 - \frac{1}{u} \right) - \text{Li}_2 \left( 1 - \frac{1}{\bar{u}} \right) \right) - 2 \bar{u} \left( \ln u - \ln \bar{u} \right) i \pi \right\} + \left[ -11 + 6 \ln \frac{\mu^2}{m_b^2} + 3\pi i \right]
\]

\[
V_{T,2} = \int_0^1 du \left\{ -4 \left( 2 + 2 \ln u - 2 \bar{u} \left( \text{Li}_2 \left( 1 - \frac{1}{u} \right) - \text{Li}_2 \left( 1 - \frac{1}{\bar{u}} \right) \right) - i \pi 2 \bar{u} \left( \ln u - \ln \bar{u} \right) \right) + \left[ 32 + 24 \ln \frac{\mu^2}{m_b^2} - 12\pi i \right] \right\}
\]

(38)
• Penguin Contributions

In the calculations of penguin contributions we also need to consider the difference between two diagrams with different topologies showed in Fig. 2. We obtain that the twist-2 parts of penguin contributions $P^{n}_{M_{2}, 2}, P^{n, EW}_{M_{2}, 2}$ are

$$
P^{n}_{M_{2}, 2} = - \frac{1}{2} C_{11} \times \left[ \frac{m_{s}}{m_{b}} \left( \frac{4}{3} \ln \frac{m_{b}}{\mu} - G(0) \right) + \left( \frac{4}{3} \ln \frac{m_{b}}{\mu} - G(1) \right) \right] 
+ C_{13} \left[ -2 \ln \frac{m_{b}}{\mu} G_{M_{2}}^{0} - GF_{M_{2}}(1) \right] - 4 C_{15} \left[ \left( \frac{1}{2} - 2 \ln \frac{m_{b}}{\mu} \right) G_{M_{2}}^{0} - GF(1) \right] 
- 8 C_{16} \left[ -2 \ln \frac{m_{b}}{\mu} G_{M_{2}}^{0} - GF_{M_{2}}(1) \right] - 8 C_{16}^{c} \left[ \left( \frac{m_{c}}{m_{b}} \right)^{2} \left( -2 \ln \frac{m_{b}}{\mu} G_{M_{2}}^{0} - GF_{M_{2}}(s_{c}) \right) \right]
$$

$$
P^{n, EW}_{M_{2}, 2} = - \frac{1}{2} \left\{ C_{12} \times \left[ \frac{m_{s}}{m_{b}} \left( \frac{4}{3} \ln \frac{m_{b}}{\mu} - G(0) \right) + \left( \frac{4}{3} \ln \frac{m_{b}}{\mu} - G(1) \right) \right] 
+ [C_{13} + N_{c} C_{14}] \left[ -2 \ln \frac{m_{b}}{\mu} G_{M_{2}}^{0} - GF_{M_{2}}(1) \right] 
- 8 [N_{c} C_{15} + C_{16}] \left[ \left( \frac{1}{2} - 2 \ln \frac{m_{b}}{\mu} \right) G_{M_{2}}^{0} - GF_{M_{2}}(1) \right] 
- 4 [C_{15} + N_{c} C_{16}] \left[ -2 \ln \frac{m_{b}}{\mu} G_{M_{2}}^{0} - GF_{M_{2}}(1) \right] 
- 4 [C_{15} + N_{c} C_{16}]^{c} \left[ \left( \frac{m_{c}}{m_{b}} \right)^{2} \left( -2 \ln \frac{m_{b}}{\mu} G_{M_{2}}^{0} - GF_{M_{2}}(s_{c}) \right) \right] \right\}
$$

where $s_{c} = (m_{c}/m_{b})^{2}, G_{M_{2}}^{0} = \int_{0}^{1} dx \phi_{M_{2}}(x)/x$ and the function $GF_{M_{2}}(s)$ is given by

$$
GF_{M_{2}}(s_{c}) = \int_{0}^{1} dx \frac{GF_{M_{2}}(s_{c}, x)}{x}
$$

Compared with twist-2 contributions, the twist-3 projection yields an additional factor of $\hat{x}$ which has appeared in penguin contributions proportional to $C_{7g}^{\text{eff}}$ and $C_{9g}^{\text{eff}}$. We therefore find

$$
P^{n}_{M_{2}, 3} = - \frac{1}{2} C_{11} \times \left[ \frac{m_{s}}{m_{b}} \left( \frac{4}{3} \ln \frac{m_{b}}{\mu} - \hat{G}(0) \right) + \left( \frac{4}{3} \ln \frac{m_{b}}{\mu} - \hat{G}(1) \right) \right] 
+ C_{13} \left[ -2 \ln \frac{m_{b}}{\mu} - \hat{G}(1) \right] - 4 C_{15} \left[ \left( \frac{1}{2} - 2 \ln \frac{m_{b}}{\mu} \right) - \hat{G}(1) \right] 
- 8 C_{16} \left[ -2 \ln \frac{m_{b}}{\mu} - \hat{G}(1) \right] - 8 C_{16}^{c} \left[ \left( \frac{m_{c}}{m_{b}} \right)^{2} \left( -2 \ln \frac{m_{b}}{\mu} - \hat{G}(s_{c}) \right) \right]
$$

$$
P^{n, EW}_{M_{2}, 3} = - \frac{1}{2} \left\{ C_{12} \times \left[ \frac{m_{s}}{m_{b}} \left( \frac{4}{3} \ln \frac{m_{b}}{\mu} - \hat{G}(0) \right) + \left( \frac{4}{3} \ln \frac{m_{b}}{\mu} - \hat{G}(1) \right) \right] 
+ [C_{13} + N_{c} C_{14}] \left[ -2 \ln \frac{m_{b}}{\mu} - \hat{G}(1) \right] 
- 8 [N_{c} C_{15} + C_{16}] \left[ \left( \frac{1}{2} - 2 \ln \frac{m_{b}}{\mu} \right) - \hat{G}(1) \right] 
- 4 [C_{15} + N_{c} C_{16}] \left[ -2 \ln \frac{m_{b}}{\mu} - \hat{G}(1) \right] 
- 4 [C_{15} + N_{c} C_{16}]^{c} \left[ \left( \frac{m_{c}}{m_{b}} \right)^{2} \left( -2 \ln \frac{m_{b}}{\mu} - \hat{G}(s_{c}) \right) \right] \right\}
$$

with

$$
\hat{G}(s_{c}) = \int_{0}^{1} dx \frac{GF(s_{c}, x)}{x}.
$$
**Hard-scattering Contributions**

Hard-scattering contributions come from Fig. 3 which read

\[
H_{S,3} = \frac{1}{m_B^2 F_1^B \to M_1} \frac{1}{8u^2 v} \left[ -u \mu_{M_i} \phi_B(\xi) \frac{\phi'_{M_1,\sigma}(u) \phi'_{M_2,\sigma}(v)}{6} + 3v m_B \phi_B(\xi) \phi_{M_1}(u) \phi_{M_2}(v) \\
-3(u + v) \mu_{M_i} \phi_B(\xi) \phi_{M_1}(u) \phi_{M_2}(v) - (u - v) \mu_{M_i} \phi_B(\xi) \frac{\phi'_{M_1,\sigma}(u) \phi'_{M_2,\sigma}(v)}{6} \\
+ u \mu_{M_i} \phi_B(\xi) \phi_{M_1}(u) \phi_{M_2}(v) \right],
\]

where \( \phi' \) means the derivative of \( \phi \). There is end-point singularity in Eq. (45) which can be treated in the way given in Appendix B.

Because \( \eta' \) is a flavor singlet there are three extra contributions related to the gluon content of \( \eta' \). They come from: the \( b \to sgg \) amplitude, spectator scattering involving two gluons, and singlet weak annihilation. As analysed in Ref. [28], the singlet weak annihilation is suppressed by at least one power of \( \Lambda_{QCD}/m_b \) in the heavy quark limit. So we need to calculate the contributions from the \( b \to sgg \) decay and spectator scattering which have not included in the results given above. In SM the relevant calculations have been carried out and results have been given in Ref. [28]. We calculate them with insertions of new operators. In order to make the paper self-contained we also list the SM results given in Ref. [28].

**Two gluon mechanism**

- **The \( b \to sgg \) amplitude**

The amplitude for \( b \to sgg \) comes from Fig. 4. We use the formula (16) in Ref. [28] directly. For an operator \( \mathcal{O}_i \) denoted arbitrary spinor and color matrices, one has (assuming the two gluons to be in a color-singlet configuration)

\[
\mathcal{A}(b \to sgg)|_{\text{Fig. } 4} = -(\bar{u}_i \Gamma_1 u_b) \langle g(q_1)g(q_2)|\text{tr} (\Gamma_2 \mathcal{A})|0\rangle,
\]

where

\[
A = \frac{\alpha_s}{4\pi N_c} \left\{ \frac{1}{12m_q} G_{\mu \nu}^A G^{A,\mu \nu} - \frac{(g - 6m_q) i\gamma_5}{48m_q^2} G_{\mu \nu}^A \tilde{G}^{A,\mu \nu} + O(1/m_q^3) \right\}.
\]
• Spectator Mechanism

The Fig. gives the spectator scattering contributions. By a straightforward calculation, we obtain the hard spectator-scattering contributions to the $B \to K\eta'$ decay amplitude using two-gluon mechanism:

$$A^{\text{spec}} = \frac{3CF\alpha_s^2}{N_c^2} C_p f_B f_K \int_0^1 \frac{d\xi}{\xi} \int_0^1 \frac{dy}{y} \left[ P_2^p(\phi_K(y) + r^K \phi_p(y)) + P_2^{\text{neu}} \phi_K(y) + r^K P_3^{\text{neu}} \phi_p(y) \right]$$

(50)

with

$$P_2^p(y) = C_1 \left[ \frac{4}{3} \ln \frac{m_b}{\mu} + \frac{2}{3} - G(s_p, y) \right] + C_3 \left[ \frac{8}{3} \ln \frac{m_b}{\mu} + \frac{4}{3} - G(0, \bar{y}) - G(1, \bar{y}) \right]$$

$$+ \left( C_4 + C_6 \right) \left[ \frac{4n_f}{3} \ln \frac{m_b}{\mu} - (n_f - 2) G(0, \bar{y}) - G(s_c, \bar{y}) - G(1, \bar{y}) \right]$$

$$- \frac{1}{2} C_{11} \left[ \frac{m_s}{m_b} \left( \frac{4}{3} \ln m_b \mu - G(0, \bar{y}) \right) + \left( \frac{4}{3} \ln \frac{m_b}{\mu} - G(1, \bar{y}) \right) \right]$$

(51)

$$P_2^{\text{neu}}(y) = -2C_{11}^{\text{eff}} + C_{13} \left[ -2 \ln \frac{m_b}{\mu} - GF(1, \bar{y}) \right]$$

$$- 4C_{15} \left[ - \frac{1}{2} - 2 \ln \frac{m_b}{\mu} - GF(1, \bar{y}) \right] - 8C_{16} \left[ - 2 \ln \frac{m_b}{\mu} - GF(1, \bar{y}) \right]$$

(52)

$$P_3^{\text{neu}}(y) = -2C_{11}^{\text{eff}} + C_{13} \left[ +1 - 2 \ln \frac{m_b}{\mu} - GF(1, \bar{y}) \right]$$

$$- 4C_{15} \left[ - \frac{3}{2} - 2 \ln \frac{m_b}{\mu} - GF(1, \bar{y}) \right] - 8C_{16} \left[ -1 - 2 \ln \frac{m_b}{\mu} - GF(1, \bar{y}) \right]$$

(53)

with $s_q = (m_q/m_b)^2$, $n_f = 5$. Obviously there is singularity arising from the end-point region in the Eq.(50) which makes us to consider the effect of $k_\perp$ in the end-point region. After involved the $k_\perp$ effect of spectator quark and turned to $b$-space, the conjugate space of $k_\perp$, Eq.(51) now reads

$$A_p^{\text{spec}} = \frac{3CF\alpha_s^2}{4N_c^2} C_p f_B f_K m_B^2 \int_0^\infty \frac{db}{b} \int_0^1 d\xi d\eta \mathcal{P}_B(\xi, b)$$

$$\times \left\{ - \left[ K_0(b\sqrt{-c}) - K_0(b\sqrt{\alpha}) \right] \left[ P_2^p(y) (\mathcal{P}_K(y, b) + r^0 \mathcal{P}_p(y, b)) + r_y^0 P_3^{\text{neu}} \mathcal{P}_p(y, b) \right] ight.$$

$$+ m_B \left[ \frac{bK_1(b\sqrt{-c}) - K_0(b\sqrt{\alpha})}{2\sqrt{-y}} \right] P_2^{\text{neu}}(y) \mathcal{P}_K(y, b) \right\}$$

(54)
where $\mathcal{P}_B(\xi, b), \mathcal{P}_K(y, b), \mathcal{P}_\pi(y, b)$ are corrected distribution amplitude including Sudakov factor \[15, 16\] and $K_{0(1)}$ are modified Bessel function of order 0(1). Numerically we find that the contributions from the two gluon mechanism are negligible.

IV. NUMERICAL RESULTS

A. Parameters input

In our numerical calculations the following values are needed:

- **Parameters related mixing of $\eta - \eta'$**
  
  We use the following input \[31\]:
  
  \[
  f_q = f_\pi, \quad f_s = \sqrt{2} f^2_\pi - f^2_\pi = 1.41 f_\pi, \\
  h_q = f_q m_\pi^2 = 0.0025\text{ GeV}^3, \quad h_s = f_s (2 m^2_\pi - m^2_s) = 0.086\text{ GeV}^3, \\
  \phi = 39.3^\circ \pm 1.0^\circ.
  \] (55)

- **Lifetime, mass and decay constants**
  
  \[
  \tau(B^0) = 1.56 \times 10^{-12}\text{ s}, \quad M_B = 5.28\text{ GeV}, \quad m_b = 4.2\text{ GeV}, \\
  m_c = 1.3\text{ GeV}, \quad m_s = 100\text{ MeV}, \quad f_B = 0.190\text{ GeV}, \quad f_K = 0.158\text{ GeV}.
  \] (56)

- **Chiral enhancement factors**
  
  For the chiral enhancement factors for the pseudoscalar mesons, $\mu_P = \frac{m_{B^0}}{m_b}$, we take
  
  \[
  R_{K^{\pm, 0}} = R_{\pi^\pm} \simeq 1.2,
  \]
  which are consistent with the values used in \[18, 31\], and
  
  \[
  R_{\eta^{(0)}}^s = \frac{m_{\eta^{(0)}}^2}{m_s m_b}.
  \]

- **Wolfenstein parameters**
  
  We use the Wolfenstein parameters fitted by Ciuchini et al \[32\]:
  
  \[
  A = 0.819 \pm 0.040, \quad \lambda = 0.2237 \pm 0.0033, \\
  \bar{\rho} = \rho(1 - \lambda^2/2) = 0.224 \pm 0.038, \quad \rho = 0.230 \pm 0.039, \\
  \bar{\eta} = \eta(1 - \lambda^2/2) = 0.317 \pm 0.040, \quad \eta = 0.325 \pm 0.039, \\
  \gamma = (54.8 \pm 6.2)^\circ, \quad \sqrt{\rho^2 + \eta^2} = 0.398 \pm 0.040.
  \] (57)

- **Form factors**

  In the paper we need two form factors: $F_{B \to K}(0) = 0.34$ and $F_{B \to \eta'}$. Compared with these rather well studied form factors, the form factors for $B \to \eta^{(0)}$ are poorly known, which has hindered theoretical predictions for $B$ decays involving $\eta^{(0)}$ very much for a long time. We adopt the following parameterization for the form factors ($P = \eta$ or $\eta'$) \[28\]:
  
  \[
  F_{0}^{B \to P}(0) = F_1 \frac{f_P^2}{f_\pi} + F_2 \frac{\sqrt{2} f_P^2 + f_\pi^2}{\sqrt{3} f_\pi},
  \] (58)

  where $F_1$ and $F_2$ both scale like $(A/m_b)^{3/2}$ in the heavy-quark limit. In our numerical analysis we set $F_1 = F_{0}^{B \to \pi}(0) = 0.28$ and take $F_2 = 0$.

B. Constraints from experiments

We impose two important constraints from $B \to X_s\gamma$ and $B_s \to \mu^+\mu^-$. Considering the theoretical uncertainties, we take $2.0 \times 10^{-4} < \text{Br}(B \to X_s\gamma) < 4.5 \times 10^{-4}$, as generally analysed in literatures. Phenomenologically, $\text{Br}(B \to X_s\gamma)$ directly constrains $|C_{7 resultList}$ and $|C_{7}\gamma(m_b)|$ at the leading order. Due to the strong enhancement factor $m_{\bar{b}}/m_b$ associated with single $\delta^{L(RL)}_{23}$ insertion term in $C_{7}\gamma(m_b), \delta^{L(RL)}_{23} (\sim 10^{-2})$ are more severely constrained than
\( \delta^{LL(RR)}_{23} \). However, if the left-right mixing of scalar bottom quark \( \delta^{LR}_{33} \) is large (~ 0.5), \( \delta^{LL(RR)}_{23} \) is constrained to be of order of \( 10^{-2} \) since the double insertion term \( \delta^{LL(RR)}_{23} \delta^{LR(RR)}_{33} \) is also enhanced by \( m_\beta/m_b \). The branching ratio \( B_s \to \mu^+\mu^- \) in MSSM is given as

\[
Br(B_s \to \mu^+\mu^-) = \frac{C_F^2\alpha\sin^2\theta}{64\pi^3}m_B^3\tau_Bf_B^2|\lambda_t|^2\sqrt{1 - 4\hat{m}^2(1 - 4\hat{m})} |C_{Q_1}(m_b) - C'_{Q_1}(m_b)|^2 + |C_{Q_2}(m_b) - C'_{Q_2}(m_b)|^2 + 2\hat{m}(C_{10}(m_b) - C'_{10}(m_b))|^2 \tag{59}
\]

where \( \hat{m} = m_\beta/m_B \). In the middle and large tan \( \beta \) case the term proportional to \( (C_1^\prime - C_{10}) \) in Eq. 59 can be neglected. The current experimental upper bound of \( Br(B_s \to \mu^+\mu^-) \) is 2.6 \times 10^{-9} \cite{33}. To translate into the constraint on \( C_{Q_{11,13}} \), we have

\[
\sqrt{|C_{Q_{11}}(m_W) - C'_{Q_{11}}(m_W)|^2 + |C_{Q_{13}}(m_W) - C'_{Q_{13}}(m_W)|^2} \lesssim 0.1 \tag{60}
\]

Because the bound constrains \( |C_{Q_i} - C'_{Q_i}| \) (\( i = 1, 2 \)), we can have values of \( |C_{Q_i}| \) and \( |C'_{Q_i}| \) larger than those in constrained MSSM (CMSSM) with universal boundary conditions at the high scale and scenarios of the extended minimal flavor violation in MSSM \cite{7} in which \( |C_{Q_i}| \) is much smaller than \( |C_{Q_i}| \). At the same time we require that predicted \( Br(B \to X_{s}\mu^+\mu^-) \) falls within 1 \( \sigma \) experimental bounds.

We also impose the current experimental lower bound \( \Delta M_s > 14.4ps^{-1} \) \cite{36} and experimental upper bound \( Br(B \to X_s g) < 9\% \) \cite{37}. Because \( \delta^{LR(RR)}_{23} \) is constrained to be of order of \( 10^{-2} \) by \( Br(B \to X_s \gamma) \), their contribution to \( \Delta M_s \) is small. The dominant contribution to \( \Delta M_s \) comes from \( \delta^{LL(RR)}_{23} \) insertion with both constructive and destructive effects compared with the SM contribution, where the too large destructive effect is ruled out, because SM prediction is only slightly above the present experiment lower bound.

As pointed out in section II, due to the gluino-bottom loop diagram contribution and the mixing of NHB induced operators onto the chromomagnetic dipole operator, the Wilson coefficients \( C_{8g}^{(l)} \) can be large, which might lead to a too large \( Br(B \to X_s g) \). So we need to impose the constraint from experimental upper bound \( Br(B \to X_s g) < 9\% \). A numerical analysis for \( C_{8g}=0 \) has been performed in Ref. \cite{24}. We carry out a similar analysis by setting both \( C_{8g} \) and \( C'_{8g} \) non-zero.

### C. Numerical results for \( B \to \phi K_S \)

In numerical analysis we fix \( m_\beta = m_\beta = 400GeV \) and \( \tan \beta = 30 \). We vary the NHB masses in the ranges of 91GeV \( \leq m_\phi \leq 135GeV \), 91GeV \( \leq m_H \leq 200GeV \) with \( m_\phi < m_H \) and 200GeV \( \leq m_A \leq 250GeV \) for the fixed mixing angle \( \alpha = 0.6, \pi/2 \) of the CP even NHBs and scan \( \delta^{AB}_{23} \) in the range \( |\delta^{AB}_{23}| \leq 0.05 \) for \( A = B \) and 0.01 for \( A \neq B \) (\( A = L, R \)).

Numerical results for \( B \to \phi K_S \) are shown in Figs. 6(b) where the correlation between \( S_{\phi K_S} \) and \( Br(B \to \phi K_S) \) is plotted. Fig. 6 is for the insertion of only one kind of chirality. Fig. 6(a), Fig. 6(b) and Fig. 6(c) correspond to the LR insertion, the LL insertion with only NHB and SM contributions included, and the LL insertion with all contributions included, respectively. We find that for the LR insertion (Fig. 6(a)) and the LL insertion (Fig. 6(c)) there are regions of parameters where \( S_{\phi K_S} \) falls in 1\( \sigma \) experimental bounds and \( Br \) is smaller than \( 1.6 \times 10^{-5} \). In the case of the LL insertion with only NHB and SM contributions included (Fig. 6(b)) \( S_{\phi K_S} \geq 0.3 \) because \( C_{12}^{(l)} = 0 \).

\footnote{\( C_{Q_{1,2}}^{(l)} \) are the Wilson coefficients of the operators \( Q_{1,2}^{(l)} \) which are Higgs penguin induced in leptonic and semileptonic B decays and their definition can be found in Ref. \cite{24}. By substituting the quark-Higgs vertex for the lepton-Higgs vertex it is straightforward to obtain Wilson coefficients relevant to hadronic B decays.}
FIG. 7: The correlation between $S_{\phi K_S}$ and Br($B \to \phi K_S$). (a) is for the LR and RL insertions, (b) is for the LL and RR insertions with only SM and NHB contributions included, and (c) is for the LL and RR insertions with the all contributions included. Current 1σ bounds are shown by the dashed lines.

FIG. 8: The correlation between $S_{\eta' K_S}$ and Br($B \to \eta' K_S$) for the insertion of only one kind of chirality. (a) is for the LR insertion, (b) is for the LL insertion with only SM and NHB contributions included, and (c) is for the LL insertion with the all contributions included. Current 1σ bounds are shown by the dashed lines.

and consequently $C_i$, i=11,...,16 can not be as large as in the case with both the LL and RR insertions due to the constraint from $B_s \to \mu^+\mu^-$. The similar result is obtained for only a RL insertion or a RR insertion. In Fig. 7 (a), (b), and (c) correspond to the LR and RL insertions, the LL and RR insertions with only NHB and SM contributions included, and the LL and RR insertions with the all contributions included, respectively. We find that there are regions of parameters where $S_{\phi K_S}$ falls in 1σ experimental bounds and Br is smaller than $1.6 \times 10^{-5}$ in all three cases. The difference among the three cases is that the size of the regions is different: the smallest ones are for the LL and RR insertions with only NHB and SM contributions included, and the biggest ones for the LL and RR insertions with the all contributions included, as expected. In the cases of the LL and RR insertions and the LR and RL insertions $S_{\phi K_S}$ can reach −0.9 or so. Comparing (a) (c) with (a) (c), one can see that the case with both the LR and RL insertions (both the LL and RR insertions) has parameter regions with negative $S_{\phi K_S}$ larger than those in the case with the LR (LL) insertion.

D. Numerical results for $B \to \eta' K_S$

Input parameters used in this subsection are the same as those in last subsection. Numerical results for $B \to \eta' K_S$ are shown in Figs. 8 where the correlation between $S_{\eta' K_S}$ and Br($B \to \eta' K_S$) is plotted. The Fig. 8 is for the insertion of only one kind of chirality. (a), (b), and (c) correspond to the LR insertion, the LL inserted with only NHB and SM contributions included, and the LL inserted with the all contributions included, respectively. In all three cases $S_{\eta' K_S} \geq 0$ and in the case of the LL inserted with only NHB and SM contributions included the minimal value of $S_{\eta' K_S}$ is 0.5. The similar result is obtained for only a RL insertion or a RR insertion. In Fig. (a) (b), and (c) correspond to the LR and RL insertions, the LL and RR insertions with only NHB and SM contributions included, and the LL and RR insertions with the all contributions included, respectively. We find that there are regions of parameters where $S_{\eta' K_S}$ falls in 1σ experimental bounds and Br is larger than $2.7 \times 10^{-5}$ and smaller than $11 \times 10^{-5}$ in the first and third cases. For the first case, i.e., the case of the LR and RL insertions, there is most of

FIG. 9: The correlation between $S_{\eta' K_S}$ and Br($B \to \eta' K_S$). (a) is for the LR and RL insertions, (b) is for the LL and RR insertions with only SM and NHB contributions included, and (c) is for the LL and RR insertions with the all contributions included. Current 1σ bounds are shown by the dashed lines.
region of parameters where $S_{9'K_S}$ is positive. In the third case, i.e., the case of the LL and RR insertions with all contributions included, the region which corresponds to positive $S_{9'K_S}$ increases. For the second case, i.e., the case of the LL and RR insertions with only NHB and SM contributions included, $S_{9'K} \geq 0.5$ in all regions of parameters, in contrast to the cases of the LR and RL insertions and the LL and RR insertions with the all contributions included. The reason is that the new contributions come mainly from the combination $C_{13}({m_W}) - C_{13}'({m_W})$ which is constrained by $B_s \to \mu^+\mu^-$. It is the same reason that make Fig. 9(b) similar to Fig. 8(b). We would like to note that our results on $Br(B \to \eta'K_S)$ can agree with the experimental measurement \[Br(B \to \eta'K) = (5.8^{+1.4}_{-1.3}) \times 10^{-5}\]

(61)

Indeed, it has been shown that the data can be explained within theoretical uncertainties in SM without introducing any new mechanism\[28\].

In order to show explicitly there is the region of parameters in which $S_{9'K_S}$ is positive and $S_{\phi K_S}$ is negative for a set of values of parameters we plot the correlation between $S_{\phi K_S}$ and $S_{9'K_S}$ in Figs. 10(a) and 11. The Fig. 10 is devoted to the case with an insertion of only one kind of chirality. Fig. 10(a) is for the LR insertion, Fig. 10(b) and Fig. 10(c) are for only NHB and SM contributions included and the all contributions included, respectively, with the LL insertion. One can see from Fig. 10(a) that there is the region in which $S_{9'K_S}$ is positive and $S_{\phi K_S}$ is negative and their minimal values are 0 and $-0.6$, respectively. Fig. 10(b) shows that with only the LL insertion there is no region in which $S_{9'K_S}$ is positive and $S_{\phi K_S}$ is negative if one includes only NHB and SM contributions. The reason is that $C_{11,13}({m_W}) = 0$ without a RR insertion (see, eg. (7)) so that the $Br(B_s \to \mu^+\mu^-)$ upper bound limits the size of $C_{11,13}$, which leads to $S_{\phi K_S} \geq 0.3$, as shown in Fig. 8(b). When switching on all SUSY contributions among which the contribution coming from the chromo-magnetic dipole operator is dominant because its Wilson coefficient can be large due to including the double insertions (see, Eq. (4)), there is the region in which $S_{9'K_S}$ is positive and $S_{\phi K_S}$ is negative and their minimal values are 0 and $-0.7$, respectively, as shown in Fig. 10(c). We would like to point out that our result in the case with only an LL insertion is different from that in Ref. [17] because we include the $\alpha_s$ corrections of hadronic matrix elements and the effects of NHB induced operators. We have also calculated the correlation between $S_{\phi K_S}$ and $S_{9'K_S}$ in the case with only an RL insertion and an RR insertion respectively. In the case with only an RR insertion, although there is the region in which $S_{9'K_S}$ is positive and $S_{\phi K_S}$ is negative but there is no region in which both $S_{9'K_S}$ and $S_{\phi K_S}$ are in agreement with data in the $1\sigma$ bound. In the case with only an RR insertion, there are some points in the parameter space for which both $S_{9'K_S}$ and $S_{\phi K_S}$ are in agreement with data in the $1\sigma$ bound.

Fig. 11 is for (a) the LR and RL insertions, (b) only NHB and SM contributions included and (c) the all contributions included with the LL and RR insertions. We can see from the figure that the region exists for all three cases. For the case of the LR and RL insertions, there is a small region in which both $S_{9'K_S}$ and $S_{\phi K_S}$ are negative. For the case of the LL and RR insertions with only NHB and SM contributions included, the region of parameters in which $S_{9'K}$ is positive and $S_{\phi K_S}$ is negative is smaller than that in the case of the LR and RL insertions and there is no region in which both $S_{9'K_S}$ and $S_{\phi K_S}$ are negative. There is almost no region in which $S_{9'K_S}$ is smaller than $-0.5$ for the case of the LL and RR insertions with the all contributions included and also for the case of LR and RL insertions.

FIG. 10: The correlation between $S_{9'K_S}$ and $S_{\phi K_S}$ for the insertion of only one kind of chirality. (a) is for the LR insertion, (b) is for the LL insertion with only SM and NHB contributions included, and (c) is for the LL insertion with the all contributions included. Current $1\sigma$ bounds are shown by the dashed lines.

FIG. 11: The correlation between $S_{9'K_S}$ and $S_{\phi K_S}$. (a) is for the LR and RL insertions, (b) is for the LL and RR insertions with only SM and NHB contributions included, and (c) is for the LL and RR insertions with the all contributions included. Current $1\sigma$ bounds are shown by the dashed lines.
The numerical results are obtained for $m_{\tilde{g}} = m_{\tilde{q}} = 400$ GeV. For smaller gluino and squark masses, the Wilson coefficient $C_{8g}^{(t)}$ becomes larger, which could make the effect on $S_{MK}$ and Br larger. However, indeed the effect is limited due to the constraint from $B \to X_s g$. For fixed $m_{\tilde{g}}$, the Wilson coefficient $C_{8g}^{(t)}$ is not sensitive to the variation of the mass of squark in the range about from 100 GeV to 1.5 TeV. Therefore, the numerical results are not sensitive to the squark mass and would have a sizable change when the gluino mass decreases. For the very big gluino and squark masses (say, several TeV), SUSY effects drop, i.e., one reaches the decoupling limit.

V. CONCLUSIONS AND DISCUSSIONS

In summary we have calculated the Wilson coefficients at LO for the new operators which are induced by NHB penguins using the MIA with double insertions in the MSSM. We have calculated the $\alpha_s$ order hadronic matrix elements of the new operators for $B \to \phi K_S$ and $B \to \eta' K_S$ in the QCD factorization approach. Using the Wilson coefficients and hadronic matrix elements obtained, we have calculated the time-dependent CP asymmetries $S_{\phi K}$ and $S_{\eta' K}$ and branching ratios for the decays $B \to \phi K_S$ and $B \to \eta' K_S$. It is shown that in the reasonable region of parameters where the constraints from $B_s \to \bar{b} s$ mixing, $\Gamma(b \to s \gamma)$, $\Gamma(b \to s q \bar{q})$, $\Gamma(b \to s \mu^+ \mu^-)$, $B \to \mu^+ \mu^-$ are satisfied, the branching ratio of the decay $B \to \phi K_S$ can be smaller than $1.6 \times 10^{-5}$, and $S_{\phi K}$ can be negative. In some regions of parameters $S_{\phi K}$ can be as low as $-0.9$. The branching ratio and the time dependent CP asymmetry of the decay for $B \to \eta' K_S$ can agree with experiments within 1σ deviation in quite a large region of parameters. In particular, our result in the case with only an LL insertion or an RR insertion is different from that in Ref. [10] because we include the $\alpha_s$ corrections of hadronic matrix elements of operators and the effects of NHB induced operators.

It is necessary to make a theoretical prediction in SM as precise as we can in order to give a firm ground for finding new physics. For the purpose, we calculate the twist-3 and weak annihilation contributions in SM using the method in Ref. [38] by which there is no any phenomenological parameter introduced. The numerical results show that the annihilation contributions to Br are negligible, the twist-3 contributions to Br are also very small, smaller than one in Ref. [38] by which there is no any phenomenological parameter introduced. The numerical results show that the new physics. For the purpose, we calculate the twist-3 and weak annihilation contributions in SM using the method

The branching ratio and the time dependent CP asymmetry

Note added

When completing the paper we received the reference [40]. In Ref. [40] the new bound of $Br(B_s \to \mu^+ \mu^-)$ is given as

$$Br(B_s \to \mu^+ \mu^-) < 5.8 \times 10^{-7} \quad \text{at 90\% confidence level.}$$

The new bound would give a more stringent constraint on the contributions of NHBs. We have carried out preliminary calculations. The preliminary results show that it is still possible that NHB contributions to $S_{MK} (M = \phi, \eta')$ alone can make a sizable even significant deviation from the SM. In other words, the qualitative conclusion in the paper is still valid if using the new bound.

f_{12}(x) = 9f_1(x) + f_2(x), \quad \frac{f_{34}(x)}{2} = 9f_3(x) + f_4(x)/2
\]

where \(B_{1,2}(x,y)\) and \(C_{1,2}(x,y)\) are defined in Ref. [39] and \(f_{1,2,3,4,50}\) in Ref. [12].

Appendix B  Coefficients \(a_i\)

We shall give the explicit expressions of coefficients \(a_i\) of the matrix element of the effective Hamiltonian in SM which are not given in the content. For the integral which contains end-point singularity, we give a corrected one by including transverse momentum effects of partons and the Sudakov factor. The coefficients \(a_i\) can generally be divided into two parts \(a_i(M_1M_2) = a_{i,1}(M_1M_2) + a_{i,II}(M_1M_2)\):

\[
\begin{align*}
  a_{1,1} &= C_1 + \frac{C_2}{N_c} \left[ 1 + \frac{C_F \alpha_s}{4\pi} V_{M_2} \right], \\
  a_{1,II} &= \frac{C_2}{N_c} \frac{C_F \alpha_s}{N_c} H, \\
  a_{2,1} &= C_2 + \frac{C_1}{N_c} \left[ 1 + \frac{C_F \alpha_s}{4\pi} V_{M_2} \right], \\
  a_{2,II} &= \frac{C_1}{N_c} \frac{C_F \alpha_s}{N_c} H, \\
  a_{3,1} &= C_3 + \frac{C_4}{N_c} \left[ 1 + \frac{C_F \alpha_s}{4\pi} V_{M_2} \right], \\
  a_{3,II} &= \frac{C_4}{N_c} \frac{C_F \alpha_s}{N_c} H, \\
  a_{4,1} &= C_4 + \frac{C_3}{N_c} \left[ 1 + \frac{C_F \alpha_s}{4\pi} V_{M_2} \right] + \frac{C_F \alpha_s}{4\pi} \frac{P_{M_2}^p}{N_c}, \\
  a_{4,II} &= \frac{C_3}{N_c} \frac{C_F \alpha_s}{N_c} H, \\
  a_{5,1} &= C_5 + \frac{C_6}{N_c} \left[ 1 + \frac{C_F \alpha_s}{4\pi} \left(-V'_{M_2}\right) \right], \\
  a_{5,II} &= \frac{C_6}{N_c} \frac{C_F \alpha_s}{N_c} \left(-H\right), \\
  a_{6,1} &= C_6 + \frac{C_5}{N_c} \left( 1 - 6 \frac{C_F \alpha_s}{4\pi} \right) + \frac{C_F \alpha_s}{4\pi} \frac{P_{M_2}^p}{N_c}, \\
  a_{6,II} &= 0, \\
  a_{7,1} &= C_7 + \frac{C_8}{N_c} \left[ 1 + \frac{C_F \alpha_s}{4\pi} \left(-V'_{M_2}\right) \right], \\
  a_{7,II} &= \frac{C_8}{N_c} \frac{C_F \alpha_s}{N_c} \left(-H\right), \\
  a_{8,1} &= C_8 + \frac{C_7}{N_c} \left( 1 - 6 \frac{C_F \alpha_s}{4\pi} \right) + \frac{\alpha}{9\pi} \frac{P_{M_2}^{p,EW}}{N_c}, \\
  a_{8,II} &= 0, \\
  a_{9,1} &= C_9 + \frac{C_{10}}{N_c} \left[ 1 + \frac{C_F \alpha_s}{4\pi} V_{M_2} \right], \\
  a_{9,II} &= \frac{C_{10}}{N_c} \frac{C_F \alpha_s}{N_c} H, \\
  a_{10,1} &= C_{10} + \frac{C_9}{N_c} \left[ 1 + \frac{C_F \alpha_s}{4\pi} V_{M_2} \right] + \frac{\alpha}{9\pi} \frac{P_{M_2}^{p,EW}}{N_c}, \\
  a_{10,II} &= \frac{C_9}{N_c} \frac{C_F \alpha_s}{N_c} H
\end{align*}
\]
where $M_2$ means the "emission" meson, which is $\phi$ in the process $B \to K\phi$ and is $\eta'$ or $K$ in the process $B \to \eta'K$. The vertex contributions in Eq. (63) are given as following:

\begin{align}
V_{M_2} &= 12 \ln \frac{m_b}{\mu} - 18 + \int_0^1 dx \, g(x) \, \Phi_{M_2}(x), \\
V'_{M_2} &= 12 \ln \frac{m_b}{\mu} - 6 + \int_0^1 dx \, g(1-x) \, \Phi_{M_2}(x), \\
g(x) &= 3 \left( \frac{1-2x}{1-x} \ln x - i\pi \right) \\
&+ \left[ 2 \text{Li}_2(x) - \ln^2 x + \frac{2\ln x}{1-x} - (3+2i\pi) \ln x - (x \leftrightarrow 1-x) \right], \quad (63)
\end{align}

The constants 18 and 6 are specific to the NDR scheme. Next, the penguin contributions are

\begin{align}
P_{M_2,2}^p &= C_1 \left[ \frac{4}{3} \ln \frac{m_b}{\mu} + \frac{2}{3} - G_{M_2}(s_p) \right] + C_3 \left[ \frac{8}{3} \ln \frac{m_b}{\mu} + \frac{4}{3} - \hat{G}_{M_2}(0) - \hat{G}_{M_2}(1) \right] \\
&+ (C_4 + C_6) \left[ \frac{4n_f}{3} \ln \frac{m_b}{\mu} - (n_f - 2)G_{M_2}(0) - G_{M_2}(s_c) - G_{M_2}(1) \right] \\
&- 2C_{8g}^{\text{eff}} \int_0^1 \frac{dx}{1-x} \Phi_{M_2}(x), \\
P_{M_2,2}^{\text{EW}} &= (C_1 + N_c C_2) \left[ \frac{4}{3} \ln \frac{m_b}{\mu} + \frac{2}{3} - G_{M_2}(s_p) \right] - 3C_{7G}^{\text{eff}} \int_0^1 \frac{dx}{1-x} \Phi_{M_2}(x), \quad (64)
\end{align}

where $n_f = 5$ is the number of light quark flavours, and $s_u = 0$, $s_c = (m_c/m_b)^2$ are mass ratios involved in the evaluation of the penguin diagrams. The small contributions from electroweak penguin operators are neglected in $P_{M_2,2}^p$ within our approximations. Similar comments apply to (65) below. The function $G_{M_2}(s)$ is given by

\begin{align}
G_{M_2}(s) &= \int_0^1 dx \, G(s - i\epsilon, 1-x) \, \Phi_{M_2}(x), \\
G(s, x) &= -4 \int_0^1 du \, u(1-u) \ln[s - u(1-u)x]. \quad (65)
\end{align}

Compared with the twist-2 terms, the twist-3 terms do not have factor $1-x$, which is cancelled in the calculation. We therefore find

\begin{align}
P_{M_2,3}^p &= C_1 \left[ \frac{4}{3} \ln \frac{m_b}{\mu} + \frac{2}{3} - \hat{G}_{M_2}(s_p) \right] + C_3 \left[ \frac{8}{3} \ln \frac{m_b}{\mu} + \frac{4}{3} - \hat{G}_{M_2}(0) - \hat{G}_{M_2}(1) \right] \\
&+ (C_4 + C_6) \left[ \frac{4n_f}{3} \ln \frac{m_b}{\mu} - (n_f - 2)\hat{G}_{M_2}(0) - \hat{G}_{M_2}(s_c) - \hat{G}_{M_2}(1) \right] - 2C_{8g}^{\text{eff}}, \\
P_{M_2,3}^{\text{EW}} &= (C_1 + N_c C_2) \left[ \frac{4}{3} \ln \frac{m_b}{\mu} + \frac{2}{3} - \hat{G}_{M_2}(s_p) \right] - 3C_{7G}^{\text{eff}}, \quad (67)
\end{align}

with

\begin{align}
\hat{G}_{M_2}(s) &= \int_0^1 dx \, G(s - i\epsilon, 1-x) \, \Phi_{M_2}^p(x). \quad (68)
\end{align}

The hard-scattering contributions $H_{M_1, M_2}$ are defined as following:

\begin{align}
H_{M_1, \phi} \propto \int d\xi du v \left[ \frac{\phi_B(\xi)}{\xi} \frac{\phi_{M_1}(u)}{u} \frac{\phi_{M_2}(v)}{v} + \frac{2\mu_{M_1}}{m_B} \frac{\phi_B(\xi)}{\xi} \frac{\phi_{M_2}(v)}{v} \frac{\phi_{\phi}(u)}{u} \right]. \quad (69)
\end{align}

We assume

\begin{align}
\phi_B(x) = N_B x^2(1-x)^2 \exp \left[ -\frac{m_B^2 x^2}{2\omega_B^2} \right], \quad (70)
\end{align}

with normalization factor $N_B$ satisfying $\int_0^1 dx \phi_B(x) = 1$, which is the popular used form in literature. Fitting various B decay data, $\omega_B$ is determined to be 0.4 GeV \cite{16}. With the Sudakov effects to cancel end-point singularity, Eq. (67)
turns into

\[
H_{M,\phi} \propto \int d\xi du dv d^2k_1 d^2k_2 \frac{-um_1^2 f_B(\xi) f_{M_1}(u) f_{M_2}(v)}{[\xi u m_1^2 + (k_1 - k_1)^2][\xi u m_1^2 + (k_1 - k_1 + k_2)^2]} + \frac{2m_1 m_2^2 f_{M_1} f_{M_2}(\xi) f_{M_2}(v)}{[\xi u m_1^2 + (k_1 - k_1)^2][\xi u m_1^2 + (k_1 - k_1 + k_2)^2]} \right].
\]

Calculating the upper integral in \( b \) space, we obtain the hard spectator scattering contribution

\[
H_{M,\phi} = \frac{4\pi^2}{N_c} \frac{f_{M_1} f_B}{F_0^B - M_1(m_q)^2 m_B^2} \int dxdydz \int bdvdb_2 db_2 \mathcal{P}_B(z, b) \mathcal{P}_{M_2}(x, b_2) \]

\[
\times \left\{ -um_1^2 f_{M_1}(y, b) K_0(vb_2) \times [\theta(b_2 - b) I_0(u b) K_0(u v) + \theta(b - b_2) I_0(u b) K_0(u v)]
\right.
\]

\[
\left. + 2uvm_1 m_2^2 \mathcal{P}_2(u b_2) \frac{b_2 K_1(vb_2)}{2v} [\theta(b - b_2) I_0(u b) K_0(u v) + \theta(b - b_2) I_0(u b) K_0(u v)] \right\}
\]

where \( K_i, I_i \) are modified Bessel functions of order \( i \) and \( \mathcal{P}_B, \mathcal{P}_{M_1}, \mathcal{P}_{M_2} \) are \( B, M_1, M_2 \) corrected meson amplitudes with the exponentials \( S_B, S_{M_2} \) and \( S_{M_1} \) respectively \[14, 10\].

**Appendix C. Implementation of \( \eta-\eta' \) mixing**

Though in the calculation of weak decay amplitudes we only consider the case with an \( \eta' \) meson in the final state, we have to include the effect from \( \eta-\eta' \) mixing. In the following discussions we use the FKS scheme to describe the mixing between \( \eta-\eta' \). The matrix elements of local operators evaluated between the vacuum and \( \eta' \), of the flavor-diagonal vector and pseudoscalar current densities, read

\[
\langle P(q)\bar{q}\gamma^\mu\gamma_5 q|0\rangle = -\frac{i}{\sqrt{2}} f^q_P q^\mu, \quad 2m_q \langle P(q)\bar{q}\gamma_5 q|0\rangle = -\frac{i}{\sqrt{2}} h^q_P,
\]

\[
\langle P(q)\bar{s}\gamma^\mu\gamma_5 s|0\rangle = -if^s_P q^\mu, \quad 2m_s \langle P(q)\bar{s}\gamma_5 s|0\rangle = -ih^s_P,
\]

where \( q = u \) or \( d \). We assume exact isospin symmetry and identify \( m_q \equiv \frac{1}{2}(m_u + m_d) \). We also need the anomaly matrix elements

\[
\langle P(q)\rangle \frac{\alpha_s}{4\pi} G^A_{\mu\nu} \tilde{G}^{A,\mu\nu}|0\rangle = a_P,
\]

where we use the convention

\[
\tilde{G}^{A,\mu\nu} = -\frac{1}{2} \epsilon^{\mu\nu\alpha\beta} G^A_{\alpha\beta} \quad (\epsilon^{0123} = -1)
\]

for the dual field-strength tensor. In all cases \( P = \eta \) or \( \eta' \) denotes the physical pseudoscalar meson state.

The Eq. (73) and Eq. (74) including ten non-perturbative parameters \( f^q_P, h^q_P, \) and \( a_P \), which however are not all independent, connect by

\[
\partial_\mu(\bar{q}\gamma^\mu \gamma_5 q) = 2im_q \bar{q}\gamma_5 q - \frac{\alpha_s}{4\pi} G^A_{\mu\nu} \tilde{G}^{A,\mu\nu}
\]

which leaves us with six independent parameters now.

The physical states are related to the flavor states in the FKS scheme by The

\[
\begin{pmatrix}
|\eta\rangle \\
|\eta'\rangle
\end{pmatrix} = \begin{pmatrix}
\cos \phi & -\sin \phi \\
\sin \phi & \cos \phi
\end{pmatrix} \begin{pmatrix}
|\eta_u\rangle \\
|\eta_d\rangle
\end{pmatrix},
\]

\[\text{(78)}\]
where $|\eta_q\rangle = (|u\bar{u}| + |d\bar{d}|)/\sqrt{2}$ and $|\eta_s\rangle = |s\bar{s}\rangle$, then the same mixing angle applies to the decay constants $f^+_P$ and $h^+_P$ with the normalization given by (73). We can re-define the decay constants in terms of $f_{s,q}$ and a mixing angle $\phi$ as

$$f^q_\eta = f_q \cos \phi, \quad f^s_\eta = -f_s \sin \phi, \quad f^s_\eta' = f_s \cos \phi,$$

and an analogous set of equations for the $h^+_P$. Inserting these results into (77) allows us to express all ten non-perturbative parameters in terms of the decay constants $f_q$, $f_s$ and the mixing angle $\phi$. We obtain

$$h_q = f_q (m^2_\eta \cos^2 \phi + m^2_{\eta'} \sin^2 \phi) - \sqrt{2} f_s (m^2_{\eta'} - m^2_\eta) \sin \phi \cos \phi, \quad (80)$$

$$h_s = f_s (m^2_{\eta'} \cos^2 \phi + m^2_\eta \sin^2 \phi) - \frac{f_q}{\sqrt{2}} (m^2_{\eta'} - m^2_\eta) \sin \phi \cos \phi, \quad (81)$$

and

$$a_\eta = -\frac{1}{\sqrt{2}} (f_q m^2_\eta - h_q) \cos \phi = -\frac{m^2_{\eta'} - m^2_\eta}{\sqrt{2}} \sin \phi \cos \phi (-f_q \sin \phi + \sqrt{2} f_s \cos \phi), \quad (82)$$

$$a_{\eta'} = -\frac{1}{\sqrt{2}} (f_q m^2_{\eta'} - h_q) \sin \phi = -\frac{m^2_{\eta'} - m^2_\eta}{\sqrt{2}} \sin \phi \cos \phi (f_q \cos \phi + \sqrt{2} f_s \sin \phi). \quad (83)$$
