Abstract

We study Lagrangian subalgebras of a semisimple Lie algebra with respect to
the imaginary part of the Killing form. We show that the variety $L$ of Lagrangian
subalgebras carries a natural Poisson structure $\Pi$. We determine the irreducible
components of $L$, and we show that each irreducible component is a smooth fiber
bundle over a generalized flag variety, and that the fiber is the product of the
real points of a De Concini-Procesi compactification and a compact homogeneous
space. We study some properties of the Poisson structure $\Pi$ and show that it
contains many interesting Poisson submanifolds.

1 Introduction

Let $\mathfrak{g}$ be a complex semi-simple Lie algebra and let Im $\langle \cdot, \cdot \rangle$ be the imaginary part
of the Killing form $\langle \cdot, \cdot \rangle$ of $\mathfrak{g}$. We will say that a real subalgebra $\mathfrak{t}$ of $\mathfrak{g}$ is Lagrangian
if $\dim_{\mathbb{R}} \mathfrak{t} = \dim_{\mathbb{C}} \mathfrak{g}$ and if Im $\langle x, y \rangle = 0$ for all $x, y \in \mathfrak{t}$.

In this paper, we study the geometry of the variety $L$ of Lagrangian subalgebras of
$\mathfrak{g}$ and show that $L$ carries a natural Poisson structure $\Pi$. We show that each irreducible
component of $L$ is smooth and is a fiber bundle over a generalized flag variety, and
the fiber is the product of the real points of a De Concini-Procesi compactification and

†Research partially supported by NSF grant DMS 9803624.
a compact homogeneous space. We study some properties of the Poisson structure \( \Pi \) and show that it contains many interesting Poisson submanifolds.

The Poisson structure \( \Pi \) is defined using the fact that \( g \), regarded as a real Lie algebra, is the double of a Lie bialgebra structure on a compact real form \( k \) of \( g \). The construction of \( \Pi \) works for any Lie bialgebra, and we present it in the first part of the paper. In the second part, we study the specific example of \( \mathcal{L} \), which we regard as the most important example since it is closely related to interesting problems in Lie theory.

We now explain our motivation and give more details of our results.

Let \((u, u^*)\) be any Lie bialgebra, let \( d \) be its double, and let \( \langle \cdot, \cdot \rangle \) be the symmetric scalar product on \( d \) given by

\[
\langle x + \xi, y + \eta \rangle = (x, \eta) + (y, \xi), \quad x, y \in u, \xi, \eta \in u^*.
\]

A subalgebra \( l \) of \( \mathfrak{d} \) is said to be Lagrangian if \( \dim l = \dim u \) and if \( \langle a, b \rangle = 0 \) for all \( a, b \in l \). Denote by \( \mathcal{L}(\mathfrak{d}) \) the set of all Lagrangian subalgebras of \( \mathfrak{d} \). It is a subvariety of the Grassmannian of \( n \)-dimensional subspaces of \( \mathfrak{d} \), where \( n = \dim u \). The motivation for studying \( \mathcal{L}(\mathfrak{d}) \) comes from a theorem of Drinfeld [D] on Poisson homogeneous spaces which we now recall briefly. More details are given in Section 2.1.

Let \((U, \pi_U)\) be a Poisson Lie group with \((u, u^*)\) as its tangent Lie bialgebra. Recall that an action of \( U \) on a Poisson manifold \((M, \pi)\) is called Poisson if the action map \( U \times M \to M \) is a Poisson map. When the action is also transitive, \((M, \pi)\) is called a \((U, \pi_U)\)-homogeneous Poisson space. In this case, Drinfeld [D] associated to each \( m \in M \) a Lagrangian subalgebra \( l_m \) of \( \mathfrak{d} \) and showed that \( l_{u \cdot m} = \text{Ad}_u l_m \) for every \( u \in U \) and \( m \in M \). Thus we have a \( U \)-equivariant map

\[
P : M \to \mathcal{L}(\mathfrak{d}) : m \mapsto l_m,
\]

where \( U \) acts on \( \mathcal{L}(\mathfrak{d}) \) by the Adjoint action. Drinfeld’s theorem says that the assignment that assigns to each \((M, \pi)\) the image of the map \( P \) in \((1)\) gives a one-to-one correspondence between the set of \( U \)-equivariant isomorphism classes of \((U, \pi_U)\)-homogeneous Poisson spaces with connected stabilizer subgroups and the set of \( U \)-orbits in a certain subset \( \mathcal{L}(\mathfrak{d})_C \) of \( \mathcal{L}(\mathfrak{d}) \) (see Section 2.1 for more details).

We prove the following theorem.

**Theorem 1.1** 1) There is a Poisson structure \( \Pi \) on \( \mathcal{L}(\mathfrak{d}) \) with respect to which the Adjoint action of \( U \) on \( \mathcal{L}(\mathfrak{d}) \) is Poisson;
2) Each $U$-orbit $O$ in $\mathcal{L}(\mathfrak{g})$ is a Poisson submanifold and consequently a $(U, \pi_O)$-homogeneous Poisson space;

3) For any $(U, \pi_U)$-homogeneous Poisson space $(M, \pi)$, the map $P$ in (2) is a Poisson map onto the $U$-orbit of $m$ for any $m \in M$.

We introduce the notation of model points in $\mathcal{L}(\mathfrak{g})$. For a homogeneous Poisson space $(M, \pi)$, let $\mathfrak{t} = P(m)$ for some $m \in M$. We show $\mathfrak{t}$ is a model point if and only if the map $P : M \to O_\mathfrak{t} = U \cdot \mathfrak{t}$ is a local diffeomorphism (and thus a covering map). When this happens, we regard $(O_\mathfrak{t}, \Pi)$ as a model for the Poisson space $(M, \pi)$.

The second part of the paper is concerned with the variety $\mathcal{L}$ of Lagrangian subalgebras of a semi-simple Lie algebra $\mathfrak{g}$ with respect to the imaginary part of its Killing form. Let $G$ be the adjoint group of $\mathfrak{g}$. Based on the Karolinsky classification of Lagrangian subalgebras of $\mathfrak{g}$ in [Ka], we prove

**Theorem 1.2** The irreducible components of $\mathcal{L}$ are smooth. Each irreducible component fibers over a generalized flag variety, and its fiber is the product of a homogeneous space and the space of real points of a De Concini-Procesi compactification of the semisimple part of a Levi subgroup of $G$.

For example, when $\mathfrak{g} = \mathfrak{sl}(2, \mathbb{C})$, there are two irreducible components: the first component is the $SL(2, \mathbb{C})$-orbit through $a + \mathfrak{n}$ and is isomorphic to $\mathbb{C}P^1$ (here $a$ consists of diagonal real trace zero matrices and $\mathfrak{n}$ strictly upper triangular matrices), and the second component contains the $SL(2, \mathbb{C})$-orbits through $\mathfrak{su}(2)$ and $\mathfrak{sl}(2, \mathbb{R})$ as open orbits, and the $SL(2, \mathbb{C})$-orbit through $i a + \mathfrak{n}$ as the unique closed orbit. The second component may be identified as $\mathbb{R}P^3$.

Let $\mathfrak{t}$ be a compact real form of $\mathfrak{g}$ and $K \subset G$ the connected subgroup with Lie algebra $\mathfrak{t}$. Then there is a natural Poisson structure $\pi_K$ on $K$ making $(K, \pi_K)$ into a Poisson Lie group such that the double of its tangent Lie bialgebra is $\mathfrak{g}$. By Theorem 1.1, each $K$-orbit in $\mathcal{L}$ is a $(K, \pi_K)$-homogeneous Poisson space, and every $(K, \pi_K)$-homogeneous Poisson space maps onto a $K$-orbit in $\mathcal{L}$ by a Poisson map. In particular, we show that every point in the (unique) irreducible component $\mathcal{L}_0$ of $\mathcal{L}$ that contains $\mathfrak{t}$ is a model point. Consequently, a number of interesting $(K, \pi_K)$-homogeneous Poisson spaces are contained in $\mathcal{L}_0$ (possibly up to covering maps) as Poisson submanifolds. Among these are all $(K, \pi_K)$-homogeneous Poisson structures on any $K/K_1$, where $K_1$ is a closed subgroup of $K$ containing a maximal torus of $K$. For example, $K/K_1$ could be any flag variety $G/Q \cong K/K_1 \cap Q$, where $Q$ is a parabolic subgroup of $G$. We
remark that it is shown in [Lu4] that all \((K, \pi_K)\)-homogeneous Poisson structures on \(K/T\), where \(T\) is a maximal torus in \(K\), can be obtained from solutions to the Classical Dynamical Yang-Baxter Equation [E-V]. Some Poisson geometrical properties of such Poisson structures are also studied in [Lu4].

We are motivated to study \((K, \pi_K)\)-homogeneous Poisson structures because of their connections to Lie theory. One remarkable example is the so-called Bruhat Poisson structure \(\pi_\infty\) [L-W] on \(K/T\). It corresponds to the Lagrangian subalgebra \(t + n\) of \(g\), where \(g = t + a + n\) is an Iwasawa decomposition of \(g\), and \(t = ia\) is the Lie algebra of \(T\). The name Bruhat Poisson structure comes from the fact that its symplectic leaves are exactly the Bruhat cells for a Bruhat decomposition of \(K/T\) [L-W]; its Poisson cohomology is isomorphic to a direct sum of \(n\)-cohomology groups with coefficients in certain principal representations of \(G\) [Lu2]; its \(K\)-invariant Poisson harmonic forms are exactly the harmonic forms introduced and studied by Kostant in [Ko]. This last fact is proved in [E-L], where we also use \(\pi_\infty\) to construct \(S^1\)-equivariantly closed forms on \(K/T\) and use them to reinterpret the Kostant-Kumar approach to the Schubert calculus on \(K/T\) [K-K]. One key fact used in [E-L] is that the Poisson structure \(\pi_\infty\) is the limit of a family \(\pi_t, t \in (0, +\infty)\), of \((K, \pi_K)\)-homogeneous symplectic structures on \(K/T\). The family \(\pi_t\) corresponds to a continuous curve in \(L\). Thus, we regard \(L\) as a natural setting for deformation problems for Poisson homogeneous spaces, and for this reason it is desirable to study its geometry.

The paper is organized as follows.

We start our discussion in Section 2 with an arbitrary Poisson Lie group \((U, \pi_U)\), its tangent Lie bialgebra \((u, u^*)\), and the variety \(L(\mathfrak{g})\) of Lagrangian subalgebras of its double \(\mathfrak{d} = u \bowtie u^*\). We first review Drinfeld’s theorem on \((U, \pi_U)\)-homogeneous spaces. We then give the construction of the Poisson structure \(\Pi\) on \(L(\mathfrak{d})\) and establish the properties listed in Theorem 1.1.

The rest of the paper is devoted to the Poisson Lie group \((K, \pi_K)\). In 3.1, we review Karolinsky’s classification of Lagrangian subalgebras, and use it to decompose \(L\) into a finite disjoint union of submanifolds \(L(S, \epsilon, d)\). The study of the closure \(\overline{L(S, \epsilon, d)}\) is reduced to studying the closure of the variety of real forms of a semisimple Lie algebra. After some preliminary results in Section 4, we identify the closure with the real points of a De Concini-Procesi compactification in Section 5. In Section 6, we apply our results to determine the irreducible components of \(L\) and show they are smooth. We also study the set of model points in \(L\) and show that every Lie algebra in
the irreducible component \( \mathcal{L}_0 \) containing \( \mathfrak{k} \) is a model point. Finally, in Section 4, we study some properties of the Poisson structure \( \Pi \). In particular, we study the \( K \)-orbits in the irreducible component \( \mathcal{L}_0 \) and the \((K, \pi_K)\)-homogeneous Poisson spaces arising from them.

We would like to thank Eugene Karolinsky and Hermann Flaschka for useful conversations, and the Banach Center for its hospitality when some of these results were found. In addition, the first author would like to thank Northwestern University and the University of Chicago and the second author the Hong Kong University of Science and Technology for their hospitality during the preparation of the paper.

2 Generalities on Lie bialgebras

2.1 Drinfeld’s theorem

In this section, we review Drinfeld’s theorem on homogeneous spaces of Poisson Lie groups in [D]. Details on Poisson Lie groups can be found in [L-W] and [K-S] and the references cited in [K-S].

Let \((U, \pi_U)\) be a Poisson Lie group with tangent Lie bialgebra \((\mathfrak{u}, \mathfrak{u}^*)\), where \(\mathfrak{u}\) is the Lie algebra of \(U\) and \(\mathfrak{u}^*\) its dual space equipped with a Lie algebra structure coming from the linearization of \(\pi_U\) at the identity element of \(U\). We will use letters \(x, y, x_1, y_1, \cdots\) to denote elements in \(\mathfrak{u}\) and \(\xi, \eta, \xi_1, \eta_1, \cdots\) for elements in \(\mathfrak{u}^*\). The pairing between elements in \(\mathfrak{u}\) and in \(\mathfrak{u}^*\) will be denoted by \(\langle \, , \rangle\).

Let \(\langle \, , \rangle\) be the symmetric non-degenerate scalar product on the direct sum vector space \(\mathfrak{u} \oplus \mathfrak{u}^*\) defined by
\[
\langle x_1 + \xi_1, x_2 + \xi_2 \rangle = (x_1, \xi_2) + (x_2, \xi_1). \tag{2}
\]
Then there is a unique Lie bracket on the \(\mathfrak{u} \oplus \mathfrak{u}^*\) such that \(\langle \, , \rangle\) is ad-invariant and that both \(\mathfrak{u}\) and \(\mathfrak{u}^*\) are its Lie subalgebras with respect to the natural inclusions. The vector space \(\mathfrak{u} \oplus \mathfrak{u}^*\) together with this Lie bracket is called the double Lie algebra of \((\mathfrak{u}, \mathfrak{u}^*)\) and we will denote it by \(\mathfrak{d} = \mathfrak{u} \bowtie \mathfrak{u}^*\). Note that \(U\) acts on \(\mathfrak{d}\) by the Adjoint action (by first mapping \(U\) to the adjoint group of \(\mathfrak{d}\)).

**Example 2.1** Let \(\mathfrak{u} = \mathfrak{k}\) be a compact semi-simple Lie algebra. Let \(\mathfrak{g} = \mathfrak{k}_\mathbb{C}\) be the complexification of \(\mathfrak{k}\) with an Iwasawa decomposition \(\mathfrak{g} = \mathfrak{k} + \mathfrak{a} + \mathfrak{n}\). Let \(\langle \, , \rangle\) be twice the imaginary part of the Killing form of \(\mathfrak{g}\). Then the pairing between \(\mathfrak{k}\) and \(\mathfrak{a} + \mathfrak{n}\) via
gives an identification of \( \mathfrak{t}^* \) and \( \mathfrak{a} + \mathfrak{n} \), and \( (\mathfrak{t}, \mathfrak{a} + \mathfrak{n}) \) becomes a Lie bialgebra whose double is \( \mathfrak{g} \). If \( K \) is any group with Lie algebra \( \mathfrak{t} \), then there is a Poisson structure \( \pi_K \) on \( K \) making \( (K, \pi_K) \) into a Poisson Lie group whose tangent Lie bialgebra is \( (\mathfrak{t}, \mathfrak{a} + \mathfrak{n}) \). This will be our most important example.

**Definition 2.2** Let \( n = \dim \mathfrak{u} \). A Lie subalgebra \( \mathfrak{l} \) of \( \mathfrak{d} \) is called **Lagrangian** if \( \langle a, b \rangle = 0 \) for all \( a, b \in \mathfrak{l} \) and if \( \dim \mathfrak{l} = n \). The set of all Lagrangian subalgebras of \( \mathfrak{d} \) will be denoted by \( \mathcal{L}(\mathfrak{d}) \).

Both \( \mathfrak{u} \) and \( \mathfrak{u}^* \) are Lagrangian. If \( D \) is the adjoint group of \( \mathfrak{d} \), then \( D \) acts on the set of Lagrangian subalgebras. In Example 2.1, any real form of \( \mathfrak{g} \) is a Lagrangian subalgebra, as is \( \mathfrak{t} + \mathfrak{n} \), where \( \mathfrak{t} = i\mathfrak{a} \) is the centralizer of \( \mathfrak{a} \) in \( \mathfrak{t} \).

Let \( (\mathcal{M}, \pi) \) be a \((\mathcal{U}, \pi_\mathcal{U})\)-homogeneous Poisson space. Recall [D] that this means that \( \mathcal{U} \) acts on \( \mathcal{M} \) transitively and that the action map \( \mathcal{U} \times \mathcal{M} \to \mathcal{M} \) is a Poisson map, where \( \mathcal{U} \times \mathcal{M} \) is equipped with the direct product Poisson structure \( \pi_\mathcal{U} \oplus \pi \). Let \( m \in \mathcal{M} \). Then being \((\mathcal{U}, \pi_\mathcal{U})\)-homogeneous, the Poisson structure \( \pi \) on \( \mathcal{M} \) must satisfy

\[
\pi(um) = u_*\pi(m) + m_*\pi_\mathcal{U}(u), \quad \forall u \in \mathcal{U}, m \in \mathcal{M}.
\]

Here \( u_* \) and \( m_* \) are respectively the differentials of the maps \( \mathcal{M} \to \mathcal{M} : m_1 \mapsto um_1 \) and \( \mathcal{U} \to \mathcal{M} : u_1 \mapsto u_1m \). Thus, \( \pi \) is totally determined by its value \( \pi(m) \in \wedge^2(T_m\mathcal{M}) \) at \( m \). Let \( U_m \subset \mathcal{U} \) be the stabilizer subgroup of \( U \) at \( m \) with Lie algebra \( \mathfrak{u}_m \). Identify \( T_m\mathcal{M} \cong \mathfrak{u}/\mathfrak{u}_m \) so that \( \pi(m) \in \wedge^2(\mathfrak{u}/\mathfrak{u}_m) \). Let \( \mathfrak{t}_m \) be the subspace of \( \mathfrak{d} \) defined by

\[
\mathfrak{t}_m = \{ x + \xi : x \in \mathfrak{u}, \xi \in \mathfrak{u}^*, \xi|_{\mathfrak{u}_m} = 0, \xi \wedge \pi(m) = x + \mathfrak{u}_m \}.
\]

**Theorem 2.3** (Drinfeld [D])

1) \( \mathfrak{t}_m \) is a Lagrangian subalgebra of \( \mathfrak{d} \) for all \( m \in \mathcal{M} \);

2) For all \( m \in \mathcal{M} \) and \( u \in \mathcal{U} \),

\[
\mathfrak{t}_m \cap \mathfrak{u} = \mathfrak{u}_m, \quad \mathfrak{Ad}_u \mathfrak{t}_m = \mathfrak{t}_{um}, \quad \forall u \in \mathcal{U}.
\]

3) Let \( \mathcal{M} \) be a \( \mathcal{U} \)-homogeneous space. A \((\mathcal{U}, \pi_\mathcal{U})\)-homogeneous Poisson structure \( \pi \) on \( \mathcal{M} \) is equivalent to a \( \mathcal{U} \)-equivariant map \( P : \mathcal{M} \to \mathcal{L}(\mathfrak{d}) : m \mapsto \mathfrak{t}_m \) such that (3) holds for all \( m \in \mathcal{M} \).
Definition 2.4 We will call $l_m$ the Lagrangian subalgebra of $\mathfrak{d}$ associated to $(M, \pi)$ at the point $m$. The map $P : M \to \mathcal{L}(\mathfrak{d})$ will be called the Drinfeld map.

Definition 2.5 Given a $U$-homogeneous space $M$, we say that a $U$-equivariant map $M \to \mathcal{L}(d) : m \mapsto l_m$ has Property I (I for intersection) if (5) is satisfied for all $m \in M$.

Thus 3) of Theorem 2.3 can be rephrased as follows: given a $U$-homogeneous space $M$, a $(U, \pi_U)$-homogeneous Poisson structure on $M$ is equivalent to a $U$-equivariant map $M \to \mathcal{L}(\mathfrak{d})$ with Property I.

Remark 2.6 We explain how a $U$-equivariant map $M \to \mathcal{L}(\mathfrak{d})$ having Property I gives a $(U, \pi_U)$-homogeneous Poisson structure on $M$: pick any $m \in M$. Because $t_m \subset \mathfrak{d}$ is maximal isotropic (this means that $\dim t_m = n$ and that $\langle a, b \rangle = 0$ for all $a, b \in t_m$) and because of (3), an easy linear algebra argument (see also Lemma 2.23) shows that there is a unique element $\pi(m) \in \wedge^2(u/u_m)$ such that (4) holds. Define a bivector field $\pi$ on $M$ by (3). This is well defined because of (6). This $\pi$ is Poisson because $l_m$ is Lagrangian. It is $(U, \pi_U)$-homogeneous because (3) holds by definition.

We now state some consequences of Theorem 2.3.

Definition 2.7 A Lagrangian subalgebra of $\mathfrak{d}$ is said to have Property C (C for closed) if the connected subgroup $U'_1$ of $U$ with Lie algebra $t \cap u$ is closed in $U$.

Note that any $t_m$ in the image of the Drinfeld map for any $(M, \pi)$ has Property C, because the connected subgroup of $U$ with Lie algebra $t_m \cap u$ is the identity connected component of the stabiser subgroup of $U$ at $m$, so it is closed in $U$. Conversely, if $t \in \mathcal{L}(\mathfrak{d})$ has Property C, we have the $U$-homogeneous space $U/U'_1$ and the $U$-equivariant map

$$U/U'_1 \longrightarrow \mathcal{L}(\mathfrak{d}) : uU'_1 \longmapsto \text{Ad}_u t.$$ 

It has Property I. More generally, suppose that $U_1$ is any closed subgroup of $U$ having the properties

A) the Lie algebra of $U_1$ is $t \cap u$;

B) $U_1$ normalizes $t$,

Then we have the $U$-equivariant map

$$U/U_1 \longrightarrow \mathcal{L}(\mathfrak{d}) : uU_1 \longmapsto \text{Ad}_u t.$$ 

It has Property I. Thus, by Theorem 2.3, we have
Corollary 2.8 Suppose that \( l \in \mathcal{L}(\mathfrak{d}) \) has Property C. Then for any closed subgroup \( U_1 \) of \( U \) having Properties A) and B), there is a \((U, \pi_u)\)-homogeneous Poisson structure on \( U/U_1 \) whose Drinfeld map is given by

\[
P : U/U_1 \rightarrow \mathcal{L}(\mathfrak{d}) : uU_1 \mapsto \text{Ad}_u l.
\]

Definition 2.9 For a Lagrangian subalgebra \( \mathfrak{t} \) of \( \mathfrak{d} \) with Property C and any subgroup \( U_1 \) of \( U \) with the above Properties A) and B), we say that the Poisson manifold \((U/U_1, \pi)\) described in Corollary 2.8 is determined by \( \mathfrak{t} \).

Denote by \( \mathcal{L}(\mathfrak{d})_C \) the set of all points in \( \mathcal{L}(\mathfrak{d}) \) with Property C. It is clearly invariant under the Adjoint action of \( U \). For every \((U, \pi_u)\)-homogeneous Poisson space \((M, \pi)\), the image of the Drinfeld map \( M \rightarrow \mathcal{L}(\mathfrak{d}) \) is a \( U \)-orbit in \( \mathcal{L}(\mathfrak{d})_C \).

Corollary 2.10 (Drinfeld [D]) The map that assigns to each \((M, \pi)\) the image of its Drinfeld map gives a one-to-one correspondence between \( U \)-equivariant isomorphism classes of \((U, \pi_u)\)-homogeneous Poisson spaces with connected stabilizer subgroups and the set of \( U \)-orbits in \( \mathcal{L}(\mathfrak{d})_C \).

We close this section by an example of a Lagrangian subalgebra \( \mathfrak{t} \) that does not have Property C.

Example 2.11 [Ka] Consider the Lie bialgebra \((\mathfrak{k}, \mathfrak{a} + \mathfrak{n})\) in Example 2.1. Let \( U = K \) be a compact connected Lie group with Lie algebra \( \mathfrak{k} \) and let \( T \) be the maximal torus of \( K \) with Lie algebra \( \mathfrak{a} \). Choose a topological generator \( t \) of \( T \) and let \( t = \exp(X), X \in \mathfrak{t} \). Let \( \mathfrak{t} = \mathbb{R} \cdot X + (\mathfrak{a} \cap (\mathbb{R} \cdot X)^\perp) + \mathfrak{n} \), where the perpendicular is computed relative to the Killing form. Then \( \mathfrak{t} \) is Lagrangian, but if \( \text{rank}(T) > 1 \) then \( \mathfrak{t} \cap \mathfrak{k} \) is not the Lie algebra of a closed subgroup of \( K \), so \( \mathfrak{t} \) does not have Property C.

2.2 A “Poisson structure” on \( \mathcal{L}(\mathfrak{d}) \)

Let \((U, \pi_u)\) be a Poisson Lie group and let \((\mathfrak{u}, \mathfrak{u}^*)\) be its tangent Lie bialgebra. Let \( \mathfrak{d} = \mathfrak{u} \bowtie \mathfrak{u}^* \) be its double Lie algebra equipped with the symmetric scalar product \( \langle \cdot, \cdot \rangle \) given by (2). Recall that \( \mathcal{L}(\mathfrak{d}) \) is the set of Lagrangian subalgebras of \( \mathfrak{d} \) with respect to \( \langle \cdot, \cdot \rangle \).
Notation 2.12 We will use $\text{Gr}(n, \mathfrak{d})$ to denote the Grassmannian of $n$-dimensional subspaces of $\mathfrak{d}$. Since the condition of being closed under Lie bracket and the condition of being Lagrangian are polynomial conditions, $\mathcal{L}(\mathfrak{d}) \subset \text{Gr}(n, \mathfrak{d})$ is an algebraic subset.

The group $U$ acts on $\text{Gr}(n, \mathfrak{d})$ by the Adjoint action and it leaves $\mathcal{L}(\mathfrak{d})$ invariant. Although $\mathcal{L}(\mathfrak{d})$ may be singular, all the $U$-orbits in $\mathcal{L}(\mathfrak{d})$ are smooth.

In this section, we will show that there is a smooth bi-vector field $\Pi$ on $\text{Gr}(n, \mathfrak{d})$ with the property $[\Pi, \Pi](l) = 0$ for every $l \in \mathcal{L}(\mathfrak{d})$, where $[\Pi, \Pi]$ is the Schouten bracket of $\Pi$ with itself. Moreover, we show that $\Pi$ is tangent to every $U$-orbit $O$ in $\mathcal{L}(\mathfrak{d})$, so $(O, \Pi)$ is a Poisson manifold. In fact, each $(O, \Pi)$ is a $(U, \pi_U)$-homogeneous Poisson space. If $(M, \pi)$ is a $(U, \pi_U)$-homogeneous Poisson space, we show that the Drinfeld map $P : M \rightarrow O$ is a Poisson map, where $O$ is the $U$-orbit of $t_m$ for any $m \in M$.

Notation 2.13 We identify $\mathfrak{d}^* \cong u^* \oplus u$ in the obvious way. Denote by $\#: \mathfrak{d}^* \rightarrow \mathfrak{d}$ the isomorphism induced by the nondegenerate pairing $\langle \cdot, \cdot \rangle$ on $\mathfrak{d}$. It is given by

$$\# : \mathfrak{d}^* \rightarrow \mathfrak{d} : \#(\xi + x) = x + \xi.$$

For $V \subset \mathfrak{d}$, we let

$$V^o = \{f \in \mathfrak{d}^* : f|_V = 0\}.$$

To define the bi-vector field $\Pi$ on $\text{Gr}(n, \mathfrak{d})$, we consider the element $R \in \wedge^2 \mathfrak{d}$ defined by

$$R(\xi_1 + x_1, \xi_2 + x_2) = (\xi_2, x_1) - (\xi_1, x_2), \quad \forall x_1, x_2 \in u, \xi_1, \xi_2 \in u^*.$$

The element $R$ is an example of a classical $r$-matrix on $\mathfrak{d}$ [K-S]. In particular, the Schouten bracket $[R, R] \in \wedge^3 \mathfrak{d}$ of $R$ with itself is ad-invariant and is given by

$$[R, R](f_1, f_2, f_3) = 2 <\#f_1, [\#f_2, \#f_3]>$$

for $f_i \in \mathfrak{d}^*$. Denote by $\chi^k(\text{Gr}(n, \mathfrak{d}))$ the space of $k$-vector fields on $\text{Gr}(n, \mathfrak{d})$ (i.e., the space of smooth sections of the $k$-th exterior power of the tangent bundle of $\text{Gr}(n, \mathfrak{d})$). The action by the adjoint group $D$ of $\mathfrak{d}$ on $\text{Gr}(n, \mathfrak{d})$ gives a Lie algebra anti-homomorphism

$$\kappa : \mathfrak{d} \rightarrow \chi^1(\text{Gr}(n, \mathfrak{d}))$$

9
whose multi-linear extension from $\wedge^k\mathfrak{g}$ to $\chi^k(\text{Gr}(n, \mathfrak{g}))$, for any integer $k \geq 1$, will also be denoted by $\kappa$.

Define the bi-vector field $\Pi$ on $\text{Gr}(n, \mathfrak{g})$ by

$$\Pi = \frac{1}{2}\kappa(R).$$

**Theorem 2.14** For every Lagrangian subalgebra $\mathfrak{t}$ of $\mathfrak{g}$ regarded as a point in $\text{Gr}(n, \mathfrak{g})$, we have

$$[\Pi, \Pi](\mathfrak{t}) = 0,$$

where $[\Pi, \Pi]$ is the Schouten bracket of $\Pi$ with itself.

**Proof.** Since $\Pi = \frac{1}{2}\kappa(R)$ and since $\kappa$ is a Lie algebra anti-homomorphism, we have

$$[\Pi, \Pi] = -\frac{1}{4}\kappa([R, R]).$$

Let $D_\mathfrak{t}$ be the stabilizer subgroup of $D$ at $\mathfrak{t}$ for the Adjoint action, and let $\mathfrak{d}_\mathfrak{t}$ be its Lie algebra. Since $\Pi$ is tangent to the $D$-orbit $D \cdot \mathfrak{t}$ in $\text{Gr}(n, \mathfrak{g})$, we only need to show that $[\Pi, \Pi] = 0$ when evaluated on a triple $(\alpha_1, \alpha_2, \alpha_3)$ of covectors in $T^*_\mathfrak{t}(D \cdot \mathfrak{t})$. The map

$$\kappa : \mathfrak{d} \longrightarrow T^*_\mathfrak{t}(D \cdot \mathfrak{t})$$

gives an identification

$$\kappa^* : T^*_\mathfrak{t}(D \cdot \mathfrak{t}) \longrightarrow \mathfrak{d}_\mathfrak{t}^\circ.$$

Thus, it suffices to show

$$[R, R](f_1, f_2, f_3) = 0$$

for $f_i \in \mathfrak{d}_\mathfrak{t}^\circ, i = 1, 2, 3$. Since $\mathfrak{t} \subset \mathfrak{d}_\mathfrak{t}$, we have $\#(\mathfrak{d}_\mathfrak{t}^\circ) \subset \#(\mathfrak{t}^\circ) = \mathfrak{t}$. It follows that

$$[R, R](f_1, f_2, f_3) = 2 < \#f_1, [\#f_2, \#f_3] \geq 0$$

because $\mathfrak{t}$ is a Lagrangian subalgebra.

Q.E.D.

**Corollary 2.15** For every $\mathfrak{t} \in \mathcal{L}(\mathfrak{g}) \subset \text{Gr}(n, \mathfrak{g})$, the bivector field $\Pi$ defines a Poisson structure on the $D$-orbit $D \cdot \mathfrak{t}$ in $\text{Gr}(n, \mathfrak{g})$. 

10
Since $[R,R] \in \wedge^3 \mathfrak{g}$ is ad-invariant, the following bivector field $\pi_-$ on $D$ is Poisson:

$$\pi_-(d) = \frac{1}{2}(r_d R - l_d R), \quad d \in D,$$

where $r_d$ and $l_d$ are respectively the differentials of the right and left translations on $D$ defined by $d$. Moreover, $(D, \pi_-)$ is a Poisson Lie group and $(U, \pi_U)$ is a Poisson subgroup of $(D, \pi_-)$ (see [Lu1]).

**Proposition 2.16** For every $t \in \mathcal{L}(\mathfrak{g})$, the Poisson manifold $(D \cdot t, \Pi)$ is $(D, \pi_-)$-homogeneous.

**Proof.** Let again $D_t$ be the stabilizer subgroup of $t$ in $D$. Then $D \cdot t \cong D/D_t$. Consider the bivector field $\Pi_1$ on $D$ defined by

$$\Pi_1(d) = \frac{1}{2} r_d R, \quad d \in D.$$

Then $\Pi = p_* \Pi_1$, where $p : D \to D/D_t$ is the natural projection and $p_*$ its differential. It is easy to check that for any $d_1, d_2 \in D$, we have

$$\Pi_1(d_1 d_2) = l_{d_1} \Pi_1(d_2) + r_{d_2} \pi_-(d_1).$$

It follows that $(D \cdot t, \Pi)$ is a $(D, \pi_-)$-homogeneous Poisson space.

Q.E.D.

Consider now the $U$-orbits in $\mathcal{L}(\mathfrak{g})$ through a point $t \in \mathcal{L}(\mathfrak{g})$. We have

**Theorem 2.17** At any $t \in \mathcal{L}(\mathfrak{g})$, the bi-vector field $\Pi$ on $\text{Gr}(n, \mathfrak{g})$ is tangent to the $U$-orbit through $t$, so that $(U \cdot t, \Pi)$ is a Poisson submanifold of $(D \cdot t, \Pi)$.

**Proof.** Regard $\Pi$ as a bivector field on the $D$-orbit $D \cdot t$, so $\Pi(t) \in \wedge^2 T_t(D \cdot t)$. Let $\Pi(t)^\#$ be the linear map

$$\Pi(t)^\# : T^*_t(D \cdot t) \to T_t(D \cdot t) :$$

$$\Pi(t)^\#(\alpha)(\beta) = \Pi(t)(\alpha, \beta), \quad \alpha, \beta \in T^*_t(D \cdot t).$$

It is enough to show that the image of $\Pi(t)^\#$ is tangent to the $U$-orbit through $t$.

By the identification, $T^*_t(D \cdot t) \to \mathfrak{g}_t^*$, it is enough to show that

$$\kappa((\xi + x) \neg R) \in T_t(U \cdot t), \quad \forall \xi + x \in \mathfrak{g}_t^*,$$
where \((\xi + x) \R R \in \mathfrak{d}\) is defined by
\[
((\xi + x) \R R)(\eta + y) = R(\xi + x, \eta + y), \quad \forall \eta + y \in \mathfrak{d}^*.
\]

We compute explicitly. It follows from the definition of \(R\) that
\[
R = \sum_{i=1}^{n} \eta_i \wedge e_i \in \wedge^2 \mathfrak{d},
\]
where \(\{e_1, \ldots, e_n\}\) is a basis for \(u\) and \(\{\eta_1, \ldots, \eta_n\}\) is its dual basis for \(u^*\). It follows that
\[
(\xi + x) \R R = \sum_{i=1}^{n} ((x, \eta_i)e_i - (\xi, e_i)\eta_i) = x - \xi.
\]

Hence
\[
\kappa((\xi + x) \R R) = \kappa(x) - \kappa(\xi).
\]

But since \(\xi + x \in \mathfrak{d}_0^*\), we have \(x + \xi \in \mathfrak{t}\), so \(\kappa(x + \xi) = 0\). Thus
\[
\kappa((\xi + x) \R R) = 2\kappa(x) \in T_1(U \cdot \mathfrak{t}).
\]

Q.E.D.

**Corollary 2.18** For every \(t \in \mathcal{L}(\mathfrak{d})\), the Poisson manifold \((U \cdot t, \Pi)\) is a \((U, \pi_U)\)-homogeneous Poisson space.

**Proof.** This follows from Proposition 2.16 because \((U, \pi_U)\) is a Poisson subgroup of \((D, \pi_-)\) and \((U \cdot t, \Pi)\) is a Poisson submanifold of \((D \cdot t, \Pi)\).

Q.E.D.

**Remark 2.19** Let \(U^*\) be the connected and simply connected group with Lie algebra \(u^*\). Then for any Lagrangian subalgebra \(t \in \mathcal{L}(\mathfrak{d})\), the orbit \(U^* \cdot t\) is also a Poisson submanifold of \((D \cdot t, \Pi)\). Indeed, the roles of \(u\) and \(u^*\) are symmetric in the definition of \(D\) and of \(\mathcal{L}(\mathfrak{d})\), but the \(R\)-matrix for the Lie bialgebra \((u^*, u)\) differs from that for \((u, u^*)\) by a minus sign. Consequently, if we denote by \(\pi_{U^*}\) the Poisson structure on \(U^*\) such that \((U^*, \pi_{U^*})\) is the dual Poisson Lie group of \((U, \pi_U)\), then every \(U^*\)-orbit in \(\mathcal{L}(\mathfrak{d})\) is a \((U^*, -\pi_{U^*})\)-homogeneous Poisson space.
We now look at the Drinfeld map $P: U \cdot t \to \mathcal{L}(\mathfrak{g})$ for the $(U, \pi_U)$-homogeneous Poisson space $(U \cdot t, \pi)$ (see Definition 2.4).

Theorem 2.20 For any $l \in \mathcal{L}(d)$, the Lagrangian subalgebra of $d$ associated to $(U \cdot l, \Pi)$ at $l$ is

$$T(l) = u_l + (u + u_l^\perp) \cap l,$$

where $u_l$ is the normalizer subalgebra of $l$ in $u$, and $u_l^\perp = \{\xi \in u^*: \xi|_{u_l} = 0\}$.

Proof. Denote by $l'$ the Lagrangian subalgebra associated to $(U \cdot l, \Pi)$ at $l$. We need to show that $l' = T(l)$. By definition,

$$l' = \{x + \xi: x \in u, \xi \in u_l^\perp, \xi \Pi(l) = x + u_l\}.$$

Let $\xi \in u_l^\perp$. Since the inclusion $(U \cdot t, \Pi) \rightarrow (D \cdot t, \Pi)$ is a Poisson map, it suffices to compute $((\kappa^*)^{-1}(\xi + x)) \Pi(l)$ for any $x \in u$ such that $\xi + x \in \mathfrak{g}_l^0$, where $\Pi(l)$ is regarded as a bi-vector at $t \in D \cdot t$, and $(\kappa^*)^{-1}: T^*_l(D \cdot t) \to \mathfrak{g}_l^0$ is the isomorphism induced by $\kappa: \mathfrak{g} \to T_l(D \cdot t)$. In the proof of Theorem 2.17, we showed that $(\kappa^*)^{-1}(\xi + x) \Pi(l) = \kappa(x)$. As a result, we see that

$$l' = \{x + \xi: \xi + x_1 \in \mathfrak{g}_l^0 \text{ for some } x_1 = x \text{ mod}(u_l)\}$$

$$= u_l + \#(\mathfrak{g}_l^0).$$

Now the inclusions $u_l \subset \mathfrak{g}_l$ and $t \subset \mathfrak{g}_l$ induce inclusions $\#(\mathfrak{g}_l^0) \subset u + u_l^\perp$ and $\#(\mathfrak{g}_l^0) \subset t$, so $\#(\mathfrak{g}_l^0) \subset (u + u_l^\perp) \cap t$. Hence,

$$u_l + \#(\mathfrak{g}_l^0) \subset u_l + (u + u_l^\perp) \cap t = T(l).$$

On the other hand, it is obvious that $T(l)$ is isotropic, so its dimension is at most $n$. Since $l'$ has dimension $n$, we must have $l' = T(l)$.

Q.E.D.

Remark 2.21 The map $T: \mathcal{L}(\mathfrak{g}) \to \mathcal{L}(\mathfrak{g})$ is not continuous in general. For example, consider the Lie bialgebra in Example 2.1 for $\mathfrak{g} = sl(3, \mathbb{C})$. Choose $H \in \mathfrak{a}$ with the property that both simple roots are positive on $H$ and consider the curve
\( \gamma_t = \exp(\text{ad}_{t H})(\mathfrak{sl}(3, \mathbb{R})) \) in \( L = L(\mathfrak{g}) \). Let \( \gamma_{\infty} \) be the limit of \( \gamma_t \) as \( t \to \infty \) in \( L \). Clearly, \( \gamma_t \) is isomorphic to \( \mathfrak{sl}(3, \mathbb{R}) \) for \( t \neq \infty \), and one can show \( \gamma_{\infty} = \mathfrak{h}^\tau + \mathfrak{n} \), where \( \mathfrak{h} = \mathfrak{a} + \mathfrak{t} \) is a Cartan subalgebra of \( \mathfrak{sl}(3, \mathbb{C}) \), and \( \tau \) is an anti-linear automorphism such that \( \dim(\mathfrak{h}^\tau \cap \mathfrak{t}) = 1 \). We will show later that when \( \mathfrak{t} \) is a real form of a complex semi-simple Lie algebra, then \( \mathfrak{t} \) is its own normalizer. It follows that \( T(\gamma_t) = \gamma_t \) for all \( t < \infty \). On the other hand, it is easy to check that \( T(\gamma_{\infty}) = \mathfrak{t} + \mathfrak{n} \). It follows that \( T \) is not continuous. This example can be generalized to any real form corresponding to a nontrivial diagram automorphism (see Remark 5.6 for a generalization of this example).

Assume now that \( (M, \pi) \) is an arbitrary \((U, \pi_U)\)-homogeneous Poisson space. Consider the Drinfeld map

\[ P : M \rightarrow \mathcal{L}(\mathfrak{g}) : m \mapsto t_m. \]

By Theorem 2.3, \( P \) is a submersion of \( M \) onto the \( U \)-orbit \( \mathcal{O} = U \cdot t_m \) in \( \mathcal{L}(\mathfrak{g}) \) for any \( m \in M \).

**Theorem 2.22** The Drinfeld map

\[ P : (M, \pi) \rightarrow (\mathcal{O}, \Pi) \]

is a Poisson map.

**Proof.** Fix \( m \in M \). Let \( \mathfrak{t} = t_m \). Then \( \mathcal{O} = U \cdot \mathfrak{t} \). Since both \((M, \pi)\) and \((\mathcal{O}, \Pi)\) are \((U, \pi_U)\)-homogeneous, it is enough to show that

\[ P_\ast \pi(m) = \Pi(\mathfrak{t}). \]

Let \( U_m \) and \( U_{\mathfrak{t}} \) be respectively the stabilizer subgroup of \( U \) at \( m \) and the normalizer subgroup of \( \mathfrak{t} \) in \( U \). Their Lie algebras are respectively \( \mathfrak{t} \cap \mathfrak{u} \) and \( \mathfrak{u}_{\mathfrak{t}} \). Since \( P \) is \( U \)-equivariant, we have \( U_m \subset U_{\mathfrak{t}} \). Identify

\[ M \cong U/U_m, \quad \mathcal{O} \cong U/U_{\mathfrak{t}}. \]

Then the map \( P \) becomes

\[ P : U/U_m \rightarrow U/U_{\mathfrak{t}} : uU_m \mapsto uU_{\mathfrak{t}}, \]

and we have

\[ \pi(m) \in \wedge^2(u/(t \cap u)), \quad \Pi(\mathfrak{t}) \in \wedge^2(u/\mathfrak{u}_{\mathfrak{t}}). \]
Thus we only need to show that $\pi(m)$ goes to $\Pi(l)$ under the map

$$j : u/(l \cap u) \rightarrow u/l : x + l \cap u \mapsto x + u_i.$$ 

But this follows from a general linear algebra fact which we state as a lemma below.

Q.E.D.

**Lemma 2.23** Let $V$ be an $n$-dimensional vector space and let $V^*$ be its dual space. On the direct sum vector space $V \oplus V^*$, consider the symmetric product $\langle , \rangle$ defined by

$$\langle x + \xi, y + \eta \rangle = (x, \eta) + (y, \xi), \quad x, y \in V, \xi, \eta \in V^*.$$ 

1) Let $V_0$ be any subspace of $V$. For $\lambda \in \wedge^2(V/V_0)$, define

$$W_\lambda = \{ x + \xi : x \in V, \xi \in V^*, \xi|_{V_0} = 0, \xi \cdot \lambda = x + V_0 \}.$$ 

Then $\lambda \mapsto W_\lambda$ is a one-to-one correspondence between elements in $\wedge^2(V/V_0)$ and maximal isotropic subspaces $W$ of $V \oplus V^*$ such that $W \cap V = V_0$.

2) Let $V_1$ be another subspace of $V$ such that $V_0 \subset V_1$. Let

$$j : V/V_0 \rightarrow V/V_1 : v + V_0 \mapsto v + V_1$$

be the natural projection. Let $\lambda_0 \in \wedge^2(V/V_0)$ and $\lambda_1 \in \wedge^2(V/V_1)$. Then $j(\lambda_0) = \lambda_1$ if and only if

$$W_{\lambda_1} = V_1 + (V \oplus V_1^+) \cap W_{\lambda_0}, \quad (8)$$

where $V_1^+ = \{ \xi \in V^* : \xi|_{V_1} = 0 \}$.

**Proof.** 1) Given $\lambda \in \wedge^2(V/V_0)$, it is easy to see that $W_\lambda$ is maximal isotropic with respect to $\langle , \rangle$ and that $W_\lambda \cap V = V_0$. Conversely, if $W$ is a maximal isotropic subspace of $V \oplus V^*$ such that $W \cap V = V_0$, then

$$\{ \xi \in V^* : x + \xi \in W \text{ for some } x \in V \} = V_0^+ = \{ \xi \in V^* : \xi|_{V_0} = 0 \}.$$ 

Define

$$f : (V/V_0)^* \rightarrow V/V_0 : \xi \mapsto x + V_0$$

15
where $\xi \in (V/V_0)^* \cong V_0^\perp$ and $x \in V$ is such that $x + \xi \in W$. Then $f$ is well defined and is skew-symmetric. Thus there exists $\lambda \in \wedge^2(V/V_0)$ such that $f(\xi) = \xi \cdot \lambda$ for all $\xi \in (V/V_0)^*$. It is then easy to check that $W = W_\lambda$.

2) One way to prove this fact is to take a basis for $V_0$, extend it first to a basis for $V_1$ and then extend it further to a basis of $V$. One can then write down all the spaces in (8) using these basis vectors and compare them. We omit the details.

Q.E.D.

As a special case of Theorem 2.22, we have

**Corollary 2.24** For any $\mathfrak{t} \in \mathcal{L}(\mathfrak{g})$ with Property C and any $(U, \pi_u)$-homogeneous space $(U/U_1, \pi)$ determined by $\mathfrak{t}$ (see Definitions 2.7 and 2.9), the map

$$P : (U/U_1, \pi) \rightarrow (U \cdot \mathfrak{t}, \Pi) : uU_1 \mapsto \text{Ad}_u \mathfrak{t}$$

is Poisson.

### 2.3 Model points

**Definition 2.25** We say that a Lagrangian subalgebra $\mathfrak{l}$ is a **model point** (in $\mathcal{L}(\mathfrak{g})$) if $\mathfrak{l} \cap u = u\mathfrak{l}$, where $u\mathfrak{l}$ is the normalizer subalgebra of $\mathfrak{l}$ in $u$.

It is easy to see that the set of model points in $\mathcal{L}(\mathfrak{g})$ is invariant under the $U$-action.

Every model point has Property C, for if $\mathfrak{t} \in \mathcal{L}(\mathfrak{g})$ is a model point, the connected subgroup $U_1'$ of $U$ with Lie algebra $\mathfrak{t} \cap u$ is the identity component of the stabilizer subgroup $U_1$ of $\mathfrak{t}$ in $U$, so $U_1'$ is closed. Consequently, $\mathfrak{t}$ determines a $(U, \pi_u)$-homogeneous Poisson structure on any $U/U_1'$, where $U_1$ is a closed subgroup of $U$, the normalizer subgroup of $\mathfrak{t}$ in $U$, and has the same Lie algebra $\mathfrak{t} \cap u = u\mathfrak{t}$ (see Corollary 2.8 and Definition 2.9). In this case, the map $P$ in (9) is a local diffeomorphism (in addition to being a Poisson map), and is thus a covering map. Therefore, the orbit $U \cdot \mathfrak{t}$, together with the Poisson structure $\Pi$, is a model (up to local diffeomorphism) of any $(U, \pi_u)$-homogeneous Poisson space $(U/U_1, \pi)$ determined by $\mathfrak{t}$. This is the reason we call $\mathfrak{t}$ a model point in $\mathcal{L}(\mathfrak{g})$.

Observe also that $\mathfrak{t}$ is a model point if and only if $T(\mathfrak{t}) = \mathfrak{t}$. 

16
Example 2.26 Consider the Lie bialgebra $(\mathfrak{t}, \mathfrak{a} + \mathfrak{n})$ in Example 2.1. The Lagrangian subalgebra $\mathfrak{l} = \mathfrak{a} + \mathfrak{n}$ is not a model point because $\mathfrak{l} \cap \mathfrak{t} = 0$ while the normalizer subalgebra of $\mathfrak{l}$ in $\mathfrak{t}$ is $\mathfrak{t} = i\mathfrak{a}$. However, $T(t) = t + \mathfrak{n}$ is a model point, as is any real form of $\mathfrak{g}$. In this case, we will show that every point in a certain irreducible component $L_0$ of $L(\mathfrak{a})$ is a model point.

When $\mathfrak{t}$ is a model point and when its normalizer subgroup $U_1$ in $U$ is not connected, the $(U, \pi_U)$-homogeneous Poisson spaces $(U/U_1, \pi)$ determined by $\mathfrak{t}$ might have non-trivial symmetries, as is shown in the following proposition.

Proposition 2.27 Let $\mathfrak{t}$ be a model point and let $(U/U_1, \pi)$ be any $(U, \pi_U)$-homogeneous Poisson space determined by $\mathfrak{t}$. Then all covering transformations for the covering map

$$P : (U/U_1, \pi) \longrightarrow (U/U_1, \Pi) : uU_1 \longmapsto uU\mathfrak{t}$$

(10)

are Poisson isometries for $(U/U_1, \pi)$.

Proof. Let $f : U/U_1 \to U/U_1$ be a covering transformation, so $P \circ f = f$. We know that $f$ is smooth because it must be of the form

$$f(uU_1) = uu_0U_1$$

for some $u_0$ in the normalizer subgroup of $U_1$ in $U$. Let $x \in U/U_1$ be arbitrary. We need to show that $f_* \pi(x) = \pi(f(x))$. Since $P$ is a local diffeomorphism, it is enough to show that $f_* \pi(x)$ and $\pi(f(x))$ have the same image under $P$. Now since $P$ is a Poisson map and since $P \circ f = f$, we have

$$P_*f_* \pi(x) = (P \circ f)_* \pi(x) = P_* \pi(x) = \Pi(P(x))$$

$$P_* \pi(f(x)) = \Pi(P(f(x))) = \Pi(P(x)).$$

Thus $P_*f_* \pi(x) = P_* \pi(f(x))$, and $f$ is a Poisson map.

Q.E.D.

In particular, in the case when $U_1 = U_1'$ is the identity connected component of $U_1$, the group $U_1/U_1'$ acts on $U/U_1'$ as symmetries for $(U, \pi_U)$-homogeneous Poisson structure on $U/U_1'$ determined by $\mathfrak{t}$. 

17
3 Lagrangian subalgebras of $\mathfrak{g}$

In the remainder of the paper, we will concentrate on the Lie bialgebra $(\mathfrak{t}, \mathfrak{a} + \mathfrak{n})$ as described in Example 2.1. We first fix more notation.

Throughout the rest of the paper, $\mathfrak{t}$ will be a compact semi-simple Lie algebra and $\mathfrak{g} = \mathfrak{t}_C$ its complexification. The Killing form of $\mathfrak{g}$ will be denoted by $\langle \langle \cdot , \cdot \rangle \rangle$. Let $K$ be a connected Lie group with Lie algebra $\mathfrak{t}$ and let $T \subset K$ be a maximal subgroup with Lie algebra $\mathfrak{t}$. Let $\mathfrak{h} = \mathfrak{t}_C \subset \mathfrak{g}$ be the complexification of $\mathfrak{t}$. Let $\Sigma$ be the set of roots of $\mathfrak{g}$ with respect to $\mathfrak{h}$ with the root decomposition

$$\mathfrak{g} = \mathfrak{h} + \sum_{\alpha \in \Sigma} \mathfrak{g}_\alpha.$$ 

Let $\Sigma_+$ be a choice of positive roots, and let $S(\Sigma_+)$ be the set of simple roots in $\Sigma_+$. We will also say $\alpha > 0$ for $\alpha \in \Sigma_+$. Set $\mathfrak{a} = i\mathfrak{t}$ and let $\mathfrak{n}$ be the complex subspace spanned by all the positive root vectors. Then we can identify $\mathfrak{t}^*$ with $\mathfrak{a} + \mathfrak{n}$ (here $\mathfrak{n}$ is regarded as a real Lie subalgebra of $\mathfrak{g}$) through the pairing defined by twice the imaginary part of the Killing form $\langle \langle \cdot , \cdot \rangle \rangle$. This way, $(\mathfrak{t}, \mathfrak{a} + \mathfrak{n})$ becomes a Lie bialgebra whose double is $\mathfrak{g} = \mathfrak{t} + \mathfrak{a} + \mathfrak{n}$ (Iwasawa Decomposition of $\mathfrak{g}$). Let $\pi_K$ be the Poisson structure on $K$ such that $(K, \pi_K)$ is a Poisson Lie group with tangent Lie bialgebra $(\mathfrak{t}, \mathfrak{a} + \mathfrak{n})$. We can describe $\pi_K$ explicitly as follows: Let $\theta$ be the complex conjugation of $\mathfrak{g}$ defined by $k$. Let $\langle \langle \cdot , \cdot \rangle \rangle_\theta$ be the Hermitian positive definite inner product on $\mathfrak{g}$ given by

$$\langle \langle x, y \rangle \rangle_\theta = - \langle \langle x, \theta y \rangle \rangle, \quad x, y \in \mathfrak{g}.$$ 

For each $\alpha \in \Sigma_+$, choose $E_\alpha \in \mathfrak{g}_\alpha$ such that

$$\langle \langle E_\alpha, E_\alpha \rangle \rangle_\theta = 1.$$

Let $E_{-\alpha} = -\theta(E_\alpha) \in \mathfrak{g}_{-\alpha}$ so that $\langle \langle E_\alpha, E_{-\alpha} \rangle \rangle_\theta = 1$. Set

$$X_\alpha = E_\alpha - E_{-\alpha} = E_\alpha + \theta(E_\alpha), \quad Y_\alpha = i(E_\alpha + E_{-\alpha}) = iE_\alpha + \theta(iE_\alpha).$$

Then

$$\mathfrak{t} = \mathfrak{t} + \text{span}_R \{ X_\alpha, Y_\alpha : \alpha \in \Sigma_+ \}.$$ 

The Poisson bivector field on $K$ is given by

$$\pi_K(k) = r_k \Lambda - l_k \Lambda, \quad k \in K,$$
where
\[ \Lambda = \frac{1}{4} \sum_{\alpha \in \Sigma_+} X_\alpha \wedge Y_\alpha \in \mathfrak{t} \wedge \mathfrak{t}. \]

Recall that a real subalgebra \( \mathfrak{t} \) of \( \mathfrak{g} \) is Lagrangian if \( \text{Im} \langle x, y \rangle = 0 \) for all \( x, y \in \mathfrak{t} \) and if \( \dim \mathfrak{t} = \dim \mathbb{C} \mathfrak{g} \). These Lagrangian subalgebras correspond to \( (K, \pi_K) \) Poisson-homogeneous spaces by Drinfeld's theorem. The set of all Lagrangian subalgebras of \( \mathfrak{g} \) will be denoted by \( \mathcal{L} \). It is an algebraic subset of the Grassmannian \( \text{Gr}(n, \mathfrak{g}) \) of \( n \)-dimensional subspaces of \( \mathfrak{g} \) (regarded as a 2\( n \)-dimensional real vector space).

In this section, we will decompose \( \mathcal{L} \) into a finite union of manifolds.

### 3.1 Karolinsky’s classification

E. Karolinsky [Ka] has determined all Lagrangian subalgebras \( \mathfrak{t} \) of \( \mathfrak{g} \). To describe his result, we need some notation. Let \( S \subset S(\Sigma_+) \) be a subset of the set of simple roots, and let \( [S] \) be the set of roots in the linear span of \( S \). Consider

\[ m_S = \mathfrak{h} \oplus \left( \bigoplus_{\alpha \in [S]} \mathfrak{g}_\alpha \right), \quad n_S = \bigoplus_{\alpha \in \Sigma_+ - [S]} \mathfrak{g}_\alpha \]

and

\[ p_S = m_S + n_S, \]

so that \( p_S \) is a parabolic subalgebra of type \( S \), \( n_S \) is its nilradical, and \( m_S \) is a Levi factor. Let \( m_{S,1} = [m_S, m_S] \) be the (semi-simple) derived algebra of \( m_S \). The center of \( m_S \) is

\[ z_S = \{ H \in \mathfrak{h} : \alpha_i(H) = 0, \forall \alpha_i \in S \}, \quad (11) \]

which is also the orthogonal complement of \( m_{S,1} \) in \( m_S \) with respect to the Killing form of \( \mathfrak{g} \) restricted to \( m_S \). Thus the restriction of the Killing form to \( z_S \) is nondegenerate, and we may consider Lagrangian subspaces of \( z_S \) (regarded as a real vector space) with respect to the restriction to \( z_S \) of the imaginary part of the Killing form.

Now for any subset \( S \) of the set of simple roots, a Lagrangian subspace \( V \) of \( z_S \), and a real form \( m_{S,1}^\tau \) of \( m_{S,1} \), set

\[ \mathfrak{t}(S, V, \tau) = m_{S,1}^\tau \oplus V \oplus n_S. \]

It is easy to see that it is a Lagrangian subalgebra of \( \mathfrak{g} \).
Definition 3.1 We will call \( l(S, V, \tau) \) the standard Lagrangian subalgebra associated to \((S, V, \tau)\).

Theorem 3.2 \([Ka]\) Every Lagrangian subalgebra of \(g\) is of the form \(\text{Ad}_k(l(S, V, \tau))\) for some \(k \in K\).

Note that the nilradical of \(\text{Ad}_k(l(S, V, \tau))\) is \(\text{Ad}_k(n_S)\). Denote by \(P_S\) the connected subgroup of \(G\) with Lie algebra \(p_S\).

Proposition 3.3 Let 
\[ l = \text{Ad}_k(l(S, V, \tau)) = \text{Ad}_{k_1}(l(S_1, V_1, \tau_1)) \]
be a Lagrangian subalgebra. Then \(S = S_1, V = V_1, k^{-1}k_1 \in P_S\), and \(\tau\) is conjugate to \(\tau_1\) in \(K \cap P_S\).

Proof. We have \(\text{Ad}_{k^{-1}k_1}(l(S_1, V_1, \tau_1)) = l(S, V, \tau)\). Using the fact that conjugate algebras have conjugate nilradicals, it follows easily that \(\text{Ad}_{k^{-1}k_1}n_{S_1} = n_S\). From the definition of \(n_S\), it follows that \(S = S_1\). Moreover, since \(p_S\) is the perpendicular complement of \(n_S\), it follows that \(\text{Ad}_{k^{-1}k_1}\) normalizes \(p_S\). Since a parabolic subgroup is the normalizer of its nilradical, \(k^{-1}k_1 \in P_S\). The remaining claims follow from the facts that \(n_S\) is an ideal and \(z_S\) is central in \(m_S\).

Q.E.D.

In the following, we study separately the pieces that come into the Karolinsky classification.

### 3.2 Lagrangian subspaces of \(\mathfrak{z}_S\)

For a subset \(S\) of the set of simple roots, let \(\mathfrak{z}_S\) be given as in \((\mathfrak{z}_S)\). Since the Killing form is nondegenerate on \(\mathfrak{z}_S\), its imaginary part \(B\) is a nondegenerate symmetric bilinear form of index \((z, z)\) on \(\mathfrak{z}_S\), now regarded as a \(2z\)-dimensional real vector space. Denote by \(L_{\mathfrak{z}_S}\) the variety of Lagrangian subspaces of \(\mathfrak{z}_S\) with respect to \(B\).

Proposition 3.4 The variety
\[ L_{\mathfrak{z}_S} = \bigcup_{\epsilon = \pm 1} L_{\mathfrak{z}_S, \epsilon} \]
is a smooth manifold of dimension \(\frac{z(z-1)}{2}\) with two connected components \(L_{\mathfrak{z}_S, \epsilon}, \epsilon = \pm 1\).

We call \(L_{\mathfrak{z}_S, 1}\) the component containing \(\mathfrak{z}_S \cap t\) and call \(L_{\mathfrak{z}_S, -1}\) the other one. Each component is Zariski closed.
Proof. The first assertion follows from the identification of \( L_{sS} \) with \( O(n) \times O(n)/O(n) \) given in [Po], Theorem 14.10. The algebraicity of each of the components can be derived from the discussion of charts in [Po] following Theorem 14.10, or by noting the corresponding fact for the space \( L_{sS,c} \) of complex linear Lagrangian subspaces of the complexification \( L_{sc} \) with respect to the nondegenerate Killing form (see [A-C-G-H], Exercise B, pp. 102-103), and verifying the easy fact that \( L_{sS} \) is the set of real points of \( L_{sS,c} \).

Q.E.D.

We remark that two Lagrangian subspaces \( V \) and \( V' \) lie in the same component if and only if \( \dim(V \cap V') = \dim(V) \text{mod} 2 \). This is proved in the complex case in [A-C-G-H], and the real case can be deduced from the complex case. It follows that \( t \cap 3_s \) and \( a \cap 3_s \) lie in the same component if and only if \( \dim(3_s) \) is even.

3.3 Real forms of \( \mathfrak{g} \)

A real form of \( \mathfrak{g} \) is clearly a Lagrangian subalgebra of \( \mathfrak{g} \). Denote by \( \mathcal{R} \) the set of all real forms of \( \mathfrak{g} \). We will recall some facts about \( \mathcal{R} \) in this section (see [O-V] or [A-B-V] for more details.)

Let \( \text{Aut}_\mathfrak{g} \) be the group of complex linear automorphisms of \( \mathfrak{g} \). Its identity component is the adjoint group \( G = \text{Int}_\mathfrak{g} \) of interior automorphisms of \( \mathfrak{g} \). Let \( \text{Aut}_{D(\mathfrak{g})} \) be the automorphism group of the Dynkin diagram of \( \mathfrak{g} \). It is well-known that there is a split short exact sequence

\[
0 \rightarrow \text{Int}_\mathfrak{g} \rightarrow \text{Aut}_\mathfrak{g} \xrightarrow{\phi} \text{Aut}_{D(\mathfrak{g})} \rightarrow 0.
\]

Let \( \theta \) be the Cartan involution of \( \mathfrak{g} \) defined by the compact real form \( \mathfrak{k} \). We will identify a real form \( \mathfrak{g}_0 \) of \( \mathfrak{g} \) with the complex conjugation \( \tau \) on \( \mathfrak{g} \) such that \( \mathfrak{g}_0 = \mathfrak{g}^\tau \). Define a map

\[
\psi : \mathcal{R} \rightarrow \text{Aut}_{D(\mathfrak{g})}
\]

as follows:

\[
\psi(\tau) = \phi(\tau \theta) = \phi(\theta \tau).
\]

To see that \( \phi(\tau \theta) = \phi(\theta \tau) \), choose \( g \in \text{Int}_\mathfrak{g} \) be such that \( \tau_1 = g \tau g^{-1} \) commutes with \( \theta \) (see [He], Theorem III.7.1, and the following remark). Then we get

\[
\phi(\tau \theta) = \phi(g^{-1} \tau_1 g \theta) = \phi(\tau_1 g \theta) = \phi(\tau_1 \theta^{-1} g \theta) = \phi(\tau_1 \theta)
\]
and similarly, $\phi(\theta \tau) = \phi(\theta \tau_1)$. Since $\tau_1$ commutes with $\theta$, we have $\phi(\tau \theta) = \phi(\theta \tau)$. In particular, we see that $\psi(\tau)$ is an involution.

Conversely, let $d$ be an involutory automorphism of the Dynkin diagram $D(g)$. Then $d$ extends to a complex linear involution $\gamma_d$ of $g$ as follows: we can choose $\gamma_d \in \text{Aut}_g$ preserving $\mathfrak{h}$ and permuting the fixed simple root vectors $E_\alpha, \alpha \in S(\Sigma_+)$ (see for example the proof of Proposition 2.7 in [A-B-V]). Then $\gamma_d(E_\alpha) = E_{\alpha d}$ and $\gamma_d(E_{-\alpha}) = E_{-\alpha d}$. If $H_\alpha = [E_\alpha, E_{-\alpha}]$, it follows that $\gamma_d(H_\alpha) = H_{\alpha d}$, and also $\gamma_d$ commutes with the Cartan involution on generators, and therefore on all of $g$.

Set

$$\mathcal{L}(g, d) = \psi^{-1}(d).$$

Then

$$\mathcal{R} = \cup_d \mathcal{L}(g, d)$$

is a finite disjoint union, where $d$ runs over the set of all involutory diagram automorphisms of $g$.

Let $\tau_d = \gamma_d \theta = \theta \gamma_d$. Then $\tau_d \in \mathcal{L}(g, d)$. To describe all the elements in $\mathcal{L}(g, d)$, consider

$$G^{-\tau_d} = \{ g \in \text{Int}_g : (g \tau_d)^2 = 1 \} = \{ g \in \text{Int}_g : \tau_d(g) = g^{-1} \}.$$ 

If $g \in G^{-\tau_d}$, then $g \tau_d$ is a real form of $g$ and $\psi(g \tau_d) = d$, so $g \tau_d \in \mathcal{L}(g, d)$. Conversely, if $\tau \in \mathcal{L}(g, d)$, then $\phi(\tau \theta) = \phi(\gamma_d)$, so $\tau = g \tau_d$ for some $g \in \text{Int}_g = \ker(\phi)$. But $\tau^2 = 1$, so $g \in G^{-\tau_d}$. Hence every real form $\tau$ in $\mathcal{L}(g, d)$ is of the form $\tau = g \tau_d$ for some $g \in G^{-\tau_d}$.

**Lemma 3.5** Every real form of $g$ is its own normalizer in $g$.

**Proof.** The proof follows easily by considering the $\pm 1$ eigenspace decomposition $g = g^+ \oplus g^-$ of $\tau$.

Q.E.D.

**Lemma 3.6** $\mathcal{L}(g, d)$ is a smooth submanifold of $\text{Gr}(n, g)$ of dimension $\dim \mathbb{C} g$.

**Proof.** Note that $\text{Int}_g$ acts on $\mathcal{L}(g, d)$ by the action $g \cdot \tau = g \tau g^{-1}$. The orbits of the larger group $\text{Aut}_g$ on the set of all real forms are the equivalence classes of real forms, and there are only finitely many of them (see [O-V]). Since $\text{Int}_g$ is the identity connected component of $\text{Aut}_g$ and $\text{Aut}_g$ has only finitely many components, it follows
that \( \text{Int}_g \) has only finitely many orbits on the set of all real forms. Since \( \mathcal{L}(g,d) \) is a subset of the set of all real forms, it follows that \( \mathcal{L}(g,d) \) is a finite union of \( \text{Int}_g \) orbits. Now the action of \( \text{Int}_g \) on \( \text{Gr}(n,g) \) by \( (g, l) \mapsto g(l) \) is smooth and \( \mathcal{L}(g,d) \subset \text{Gr}(n,g) \) is a disjoint union of finitely many \( \text{Int}_g \)-orbits, it follows that each \( \text{Int}_g \)-orbit in \( \mathcal{L}(g,d) \) is a smooth submanifold of \( \text{Gr}(n,g) \). Moreover, by Lemma 3.5, all orbits have the same dimension. Thus, \( \mathcal{L}(g,d) \) is a smooth submanifold of \( \text{Gr}(n,g) \) of dimension \( \dim \mathcal{C} \).

Q.E.D.

We will show later that the closure of \( \mathcal{L}(g,d) \) in \( \mathcal{L} \) is a smooth, compact and connected submanifold of \( \text{Gr}(n,g) \).

### 3.4 Model points

**Lemma 3.7** The normalizer of the Lagrangian subalgebra \( \text{Ad}_k(\mathfrak{t}(S,V,\tau)) \) in \( g \) is

\[
\text{Ad}_k(\mathfrak{r}(S,\tau)) := \text{Ad}_k(\mathfrak{m}_{S,1}^\tau \oplus \mathfrak{z}_S \oplus \mathfrak{n}_S).
\]

**Proof.** It suffices to prove the statement when \( k = e \), the identity element of \( K \). It is clear that \( \mathfrak{r}(S,\tau) \) normalizes \( \mathfrak{t}(S,V,\tau) \). Conversely, if \( X \in g \) normalizes \( \mathfrak{t}(S,V,\tau) \), it normalizes its nilradical \( \mathfrak{n}_S \), so it normalizes the perpendicular \( \mathfrak{p}_S \) of \( \mathfrak{n}_S \). Since \( \mathfrak{p}_S \) is parabolic, it equals its own normalizer, so \( X \in \mathfrak{p}_S \). Write \( X = X_1 + X_2 \), with \( X_1 \in \mathfrak{m}_S \) and \( X_2 \in \mathfrak{n}_S \). Then \( X_1 \) normalizes \( \mathfrak{m}_{S,1}^\tau \). It follows from Lemma 3.5 that \( X_1 \in \mathfrak{m}_{S,1}^\tau + \mathfrak{z}_S \).

Q.E.D.

**Proposition 3.8** The Lagrangian subalgebra \( \text{Ad}_k(\mathfrak{t}(S,V,\tau)) \) is a model point if and only if \( V = \mathfrak{z}_S \cap \mathfrak{t} \).

**Proof.** Since the set of model points is \( K \)-invariant, it suffices to prove the proposition when \( k = e \). Let \( N_\mathfrak{t}(\mathfrak{t}(S,V,\tau)) \) be the normalizer of \( \mathfrak{t}(S,V,\tau) \) in \( \mathfrak{t} \). By the previous lemma, the quotient

\[
N_\mathfrak{t}(\mathfrak{t}(S,V,\tau)/\mathfrak{t} \cap \mathfrak{t}(S,V,\tau) = (\mathfrak{z}_S \cap \mathfrak{t})/(\mathfrak{t} \cap \mathfrak{t}),
\]

since \( \mathfrak{z}_S \cap \mathfrak{t} = \mathfrak{z}_S \cap \mathfrak{t} \). The proposition now follows from the definition of model points.
Remark 3.9 In fact, essentially the same argument shows that if $l = \text{Ad}_k(l(S,V,\tau))$, then $T(l) = \text{Ad}_k(l((S,3S \cap t, \tau))$ (see Theorem 2.20 for the definition of $T(l)$). It follows that $T(T(l)) = T(l)$ for $l \in \mathcal{L}$. For a general Lie bialgebra, $T \circ T \neq T$. Indeed, for a Lie algebra $u$, we can form a Lie bialgebra $(u, u^*)$, where $u^*$ has the abelian Lie algebra structure. Its double is the semi-direct product Lie algebra structure on $u + u^*$ defined by the co-adjoint action of $u$ on $u^*$. Consider the case when $u$ is the three dimensional Heisenberg algebra with basis $\{X,Y,Z\}$ with $Z$ central and $[X,Y] = Z$, and let $f_X, f_Y, f_Z$ be the dual basis. Let $l$ be the Lagrangian subalgebra spanned by $X, f_Y$ and $f_Z$. Then $T(l)$ is spanned by $X, Z$ and $f_Y$ while $T(T(l)) = u$.

Corollary 3.10 $G$ preserves the set of model points.

Proof. It suffices to consider model points $l((S,3S \cap t, \tau)$. Let $P_S, M_S$ and $N_S$ be the connected Lie groups with Lie algebra $p_S, m_S$ and $n_S$ respectively. Since $K$ acts transitively on $G/P_S$ and preserves the set of model points, it suffices to prove that $Ad_p(l((S,3S \cap t, \tau))$ is a model point for $p \in P_S$. Using the Levi decomposition $P_S = M_S N_S$ we write $p = mn$. Since $Ad_n(l((S,3S \cap t, \tau) = l((S,3S \cap t, \tau)$, it suffices to prove that $Ad_m$ preserves model points in $p_S$, which follows because $M$ acts trivially on $3S$.

Q.E.D.

Remark 3.11 In general, the adjoint group of the double Lie algebra does not preserve the set of model points. Indeed, let $\mathfrak{g}$ be a semisimple Lie algebra with triangular decomposition $\mathfrak{g} = \mathfrak{n} + \mathfrak{h} + \mathfrak{n}_-$, Borel subalgebra $\mathfrak{b}_+ = \mathfrak{h} + \mathfrak{n}$ and opposite Borel $\mathfrak{b}_- = \mathfrak{h} + \mathfrak{n}_-$. Then the Lie algebra $\mathfrak{d} = \mathfrak{g} \oplus \mathfrak{h}$ is the double of the pair $(\mathfrak{b}_+, \mathfrak{b}_-)$ with embeddings $i_\pm : \mathfrak{b}_\pm \to \mathfrak{d}$ given by $i_\pm(H + x) = (H + x, \pm H)$ with $H \in \mathfrak{h}$, $x \in \mathfrak{n}$ or $\mathfrak{n}_-$. Let $n \in N_G(t)$ be a representative for the long element of the Weyl group. Then although $\mathfrak{b}_+$ is clearly a model point, $Ad_n(\mathfrak{b}_+)$ is not a model point.
3.5 Lagrangian data

**Definition 3.12** A triple \((S, \epsilon, d)\) is called Lagrangian datum if \(S \subseteq S(\Sigma_+)\) is a subset of the set of simple roots, \(\epsilon = \pm 1\), and \(d\) is a diagram automorphism for the Dynkin diagram \(D(m_{S,1})\) of \(m_{S,1}\). If \(t = \text{Ad}_k(t(S,V,\tau)), k \in K\), is a Lagrangian subalgebra, then \(t\) has associated Lagrangian data \(\Phi(t) = (S, \epsilon, d)\), where \(\epsilon = 1\) if \(V\) lies in the same connected component of \(L_{\mathfrak{z}_s}\) as \(\mathfrak{z}_s \cap t\) and is \(-1\) otherwise, and \(d\) is the diagram automorphism of \(m_{S,1}\) defined by \(\tau\). It follows from Proposition 3.3 that the triple \((S, \epsilon, d)\) is determined by \(t\).

Given Lagrangian datum \((S, \epsilon, d)\), we let

\[ \mathcal{L}(S, \epsilon, d) = \{ t : \Phi(t) = (S, \epsilon, d) \}. \]

Then

\[ \mathcal{L} = \bigcup_{(S, \epsilon, d)} \mathcal{L}(S, \epsilon, d). \]

Note that this is a finite disjoint union.

**Proposition 3.13** For each Lagrangian datum \((S, \epsilon, d)\), \(\mathcal{L}(S, \epsilon, d)\) is a smooth submanifold of the Grassmannian \(\text{Gr}(n, \mathfrak{g})\) of dimension \(\dim(t) + \frac{z(z-3)}{2}\), and it fibers over \(G/P_S\) with the fiber being the product of \(L_{\mathfrak{z}_s} \times L(m_{S,1}, d)\).

**Proof.** Consider the subset

\[ \mathcal{L}_{p_S}(S, \epsilon, d) = \{ t(S, V, \tau) \} \]

of all standard Lagrangian subalgebras (see Definition 3.1) attached to the Lagrangian datum \((S, \epsilon, d)\). It can be identified with \(\mathcal{L}(m_{S,1}, d) \times \mathcal{L}(z, z_S)\) as a submanifold of the Grassmannian \(\text{Gr}(m, \mathfrak{n})\). Indeed, \(\mathcal{L}(m_{S,1}, d)\) is a submanifold of the Grassmannian of \(\text{Gr}(m, m_{S,1})\) where \(m = \dim(m_{S,1})\), \(\mathcal{L}(z, z_S)\) is a submanifold of \(\text{Gr}(z, z_S)\), and the direct sum map \(\text{Gr}(m, m_{S,1}) \times \text{Gr}(z, z_S) \to \text{Gr}(n, \mathfrak{g})\), \((U, V) \mapsto U \oplus V \oplus n_S\) is a closed embedding.

We consider the multiplication map

\[ m : K \times_{K \cap P_S} \mathcal{L}_{p_S}(S, \epsilon, d) \to \mathcal{L}(S, \epsilon, d), \quad m(k, t) = \text{Ad}_k(t) \]

The fiber product is a smooth manifold since it is a fiber bundle over \(K/K \cap P_S \cong G/P_S\) with smooth fiber \(\mathcal{L}_{p_S}(S, \epsilon, d)\). The map \(m\) is onto by the Karolinsky classification.
Theorem 3.2, and it is clearly smooth and proper. We will show that it is an immersion, and it will follow that \( L(S, \epsilon, d) \) is a smooth submanifold of \( \text{Gr}(n, g) \).

The fact that \( m \) is injective follows from Proposition 3.3. In order to show that the tangent map \( m_* \) is injective, it suffices to show \( m_* \) is injective at points of the form \((e, t(S, V, \tau))\) by \( K \)-equivariance. Recall that the tangent space at a plane \( U \) to the Grassmannian \( \text{Gr}(n, V) \) of \( n \)-planes in a space \( V \) can be identified with \( \text{Hom}(U, V/U) \). Using this identification, the tangent space to the fiber product \( K \times_{K \cap \mathfrak{p}_S} \text{Gr}(n, \mathfrak{p}_S) \) at \( l(S, V, \tau) \) is the quotient of \( k \oplus \text{Hom}(l(S, V, \tau), \mathfrak{p}_S/\mathfrak{t}(S, V, \tau)) \) by the relation \((X - Y, \xi(Y) + Z) \sim (X, Z)\), where \( X \in \mathfrak{t}, Y \in \mathfrak{t} \cap \mathfrak{p}_S, \xi(Y) \) is the induced vector field at \( \mathfrak{t}(S, V, \tau) \), and \( Z \in \text{Hom}(\mathfrak{t}(S, V, \tau), \mathfrak{p}_S/\mathfrak{t}(S, V, \tau)) \). Observe that for \( Z \) to be tangent to the fiber \( L_{\mathfrak{p}_S}(S, \epsilon, d) \), we must have \( Z : \mathfrak{n}_S \to 0 \). When we identify the tangent space to \( \text{Gr}(n, \mathfrak{g}) \) at \( l(S, V, \tau) \) with \( \text{Hom}(l(S, V, \tau), \mathfrak{g}/\mathfrak{t}(S, V, \tau)) \), the tangent map is \( m_*(X, Z) = \xi(X) + Z \), where \( \xi(X) \) is the induced vector field. Now the claim that \( m_* \) is injective follows since for any \( X \notin \mathfrak{t} \cap \mathfrak{p}_S, \xi(X) \cdot \mathfrak{n}_S \not\subset \mathfrak{t}(S, V, \tau) \). To verify this last assertion, let \( X \in \mathfrak{t} \setminus \mathfrak{t} \cap \mathfrak{p}_S \), and choose a maximal root \( \alpha \notin [S] \) such that the projection \( p_{-\alpha}(X) \) of \( X \) to the \( \mathfrak{g}_{-\alpha} \) root space is nonzero. Then \([X, \mathfrak{g}_\alpha] = [p_{-\alpha}(X), \mathfrak{g}_\alpha] + Y\) where \( \ll Y, Y \gg = \ll Y, [p_{-\alpha}(X), \mathfrak{g}_\alpha] \gg = 0 \). Since \([p_{-\alpha}(X), \mathfrak{g}_\alpha] = [\mathfrak{g}_\alpha, \mathfrak{g}_{-\alpha}]\), which is a 2-dimensional real vector space on which the imaginary part of the Killing form is not isotropic, it follows that \([X, \mathfrak{g}_\alpha]\) is not isotropic. Thus, \([X, \mathfrak{g}_\alpha]\) is not contained in any Lagrangian subalgebra.

The dimension statement follows from Proposition 3.4 and Lemma 3.6.

Q.E.D.

Remark 3.14 Note that \( G \) preserves \( L(S, \epsilon, d) \). The proof is similar to that of Corollary 3.10.

Example 3.15 When \( S \) is the set of all simple roots, we have \( \mathfrak{m}_S = \mathfrak{g} \) and \( \epsilon \) can only be 1, so \( L(S, \epsilon, d) = L(\mathfrak{g}, d) \).

Q.E.D.

Example 3.16 For \( \mathfrak{g} = \mathfrak{sl}(2, \mathbb{C}) \), there are three \( L(S, \epsilon, d) \)'s. First, \( L(S(\Sigma_+), 1, \text{id}) \) is a disjoint union of the two symmetric spaces \( SO(3, \mathbb{C})/SO(3, \mathbb{R}) \) and \( SO(3, \mathbb{C})/SO(2, 1) \),
where the first piece consists of compact real forms and the second piece consists of real forms isomorphic to \(so(2,1)\). \(L(\emptyset, 1, \text{id})\) is the \(SL(2, \mathbb{C})\) orbit of \(t + n\) and is isomorphic to \(\mathbb{C}P^1\). \(L(\emptyset, -1, \text{id})\) is also isomorphic to \(\mathbb{C}P^1\), and is the \(SL(2, \mathbb{C})\) orbit through \(a + n\). As we will show in Section 6, \(L(\emptyset, 1, \text{id}) \subset L(S(\Sigma_+), 1, \text{id})\). This last closure can be identified with \(\mathbb{R}P^3\), the projectivization of \(2 \times 2\) Hermitian matrices.

In case \(g = sl(3)\), there are eight \(L(S, \epsilon, d)\)'s. \(L(S(\Sigma_+), 1, \text{id})\) is a union of components consisting of the real forms isomorphic to \(su(p, 3 - p)\). It is a union of symmetric spaces. Let \(\sigma\) be the nontrivial involution of the Dynkin diagram of \(sl(3)\). Then \(L(S(\Sigma_+), 1, \sigma)\) consists of real forms isomorphic to \(sl(3, \mathbb{R})\). There are four pieces of the form \(L(\alpha_i, \pm 1, \text{id})\) corresponding to the two choices of \(\alpha_i\) and the two choices of \(\pm 1\). Each of these pieces fibers over \(G/P_i\) for a parabolic \(P_i\) with the fiber being a symmetric space for \(SL(2, \mathbb{C})\). The final two components are of the form \(L(\emptyset, \pm 1, \text{id})\). These are bundles over the full flag variety \(G/B\) with the fiber being a component of the variety of Lagrangian subspaces of \(\mathbb{R}^4\) with respect to a quadratic form of index \((2, 2)\). The only nontrivial inclusions are \(L(\alpha_i, 1, \text{id}) \subset \overline{L(S(\Sigma_+), 1, \text{id})}\).

Because of the fiber bundle decomposition of \(L(S, \epsilon, d)\) and the fact that the base and \(L_{ss, \epsilon}\) are compact, the study of the closure \(\overline{L(S, \epsilon, d)}\) can be reduced to the study of \(\overline{L(g, d)}\) for \(g\) semisimple. In the following Sections 4 and 5, we show that \(\overline{L(g, d)}\) is a smooth connected submanifold of \(Gr(n, g)\). We will also determine its decomposition into \(G\)-orbits. These results will be applied in Section 6 to show that \(\overline{L(S, \epsilon, d)}\) is a smooth submanifold of \(Gr(n, g)\).

4 Extended signatures and the corresponding Lagrangian subalgebras of \(g\)

In this section, we give examples of Lagrangian subalgebras of \(g\) that lie in \(\overline{L(g, d)}\). They are obtained by considering extended signatures of roots of \(g\) as slightly generalized from \([O-S]\). They will be used in Section 5 to describe \(G\)-orbits in \(\overline{L(g, d)}\).

4.1 Extended signatures

Recall that

\[ S(\Sigma_+) = \{\alpha_1, \alpha_2, ..., \alpha_l\} \]
is the set of simple roots in $\Sigma_+$. Let $d$ be an involutory automorphism of the Dynkin diagram of $\mathfrak{g}$.

**Definition 4.1** An *extended $d$-signature* of the root system $\Sigma$ is a map $\sigma : \Sigma \to \{-1, 0, 1\}$ satisfying

$$\sigma(\alpha) = \prod \sigma(\alpha_i)^{m_i}, \text{ where } \alpha = \sum_{i=1}^l m_i \alpha_i$$

(12)

$$\sigma(d(\alpha_i)) = \sigma(\alpha_i).$$

(13)

We say that $\sigma$ is a *$d$-signature* if $\sigma(\alpha) \neq 0$ for any $\alpha \in \Sigma$.

An extended $d$-signature $\sigma$ is determined by its value on the simple roots. If $\sigma$ is an extended $d$-signature, let

$$\text{supp}(\sigma) = \{\alpha \in \Sigma : \sigma(\alpha) \neq 0\}.$$  

Then $S_\sigma := S(\Sigma_+) \cap \text{supp}(\sigma)$ is $d$-invariant. If we use $[S_\sigma]$ to denote the set of roots that are in the linear span of $S_\sigma$, then

$$\text{supp}(\sigma) = [S_\sigma].$$

Let

$$S_{\sigma,1} = \{\alpha_i \in S(\Sigma_+) : \sigma(\alpha_i) = -1\}, \quad \tilde{\rho}_1 = \sum_{\alpha_i \in S_{\sigma,1}} \tilde{h}_i \in \mathfrak{a},$$

where $\{\tilde{h}_i : i = 1, \ldots, l\} \subset \mathfrak{a}$ is the set of fundamental coweights corresponding to the simple roots, namely $\alpha_i(\tilde{h}_j) = \delta_{i,j}$ for $i, j = 1, \ldots, l$. Then

$$\sigma(\alpha) = \begin{cases} 0, & \alpha \notin [S_\sigma] \\ (-1)^{\alpha(\tilde{\rho}_1)}, & \alpha \in [S_\sigma]. \end{cases}$$

(14)

Conversely, for any $d$-invariant subset $S$ of $S(\Sigma_+)$ and any $d$-invariant subset $S_1$ of $S$, there is an extended $d$-signature $\sigma$ such that $S = S_\sigma$ and $S_1 = S_{\sigma,1}$.

For an extended $d$-signature $\sigma$, let

$$m_\sigma = m_{S_\sigma} = \mathfrak{h} \oplus \bigoplus_{\alpha \in [S_\sigma]} \mathfrak{g}_\alpha; \quad n_\sigma = n_{S_\sigma} = \bigoplus_{\alpha \in \Sigma_+ - [S_\sigma]} \mathfrak{g}_\alpha; \quad p_\sigma = p_{S_\sigma} = m_\sigma \oplus n_\sigma$$
as in the notation in Section 3.1. Also let $\mathfrak{z}_\sigma = \mathfrak{z}_{S\sigma}$ be the center of $m_\sigma$, and let

$$n_{\sigma,-} = \bigoplus_{\alpha \in -\Sigma_+, \sigma(\alpha) = 0} g_\alpha, \quad m_{\sigma,1} = [m_\sigma, m_\sigma].$$

Then $\sigma$ determines a complex linear involution $a_\sigma$ of $m_\sigma$ by

$$a_\sigma|_H = \text{id}, \quad a_\sigma|_{g_\alpha} = \sigma(\alpha) \cdot \text{id},$$

where $\alpha \in \text{supp}(\sigma)$. In other words,

$$a_\sigma = \text{Ad}_{\exp(\pi i \hat{\rho}_1)}.$$

Let $\tau_d = \gamma_d \theta$ be the conjugate linear involution of $\mathfrak{g}$ discussed in Section 3.3. Then it is routine to check that $\tau_{d,\sigma} := a_\sigma \tau_d$ is a conjugate linear involution of $m_\sigma$ so the Lie algebra

$$\mathfrak{k}_{d,\sigma} = m_{\tau_{d,\sigma}}$$

is a real form of $m_\sigma$. Set

$$l_{d,\sigma} = \mathfrak{k}_{d,\sigma} + n_\sigma.$$ 

It is easy to check that $l_{d,\sigma}$ is a Lagrangian subalgebra of $\mathfrak{g}$.

Since $S_\sigma$ is $d$-invariant, $m_\sigma$ is invariant under $\gamma_d$. Regarded as a complex automorphism of $m_{\sigma,1}$, $\gamma_d$ defines an automorphism of the Dynkin diagram of $m_{\sigma,1}$ which is just $d|_{S_\sigma}$. Let $\mathfrak{z}_{\tau_d}$ be the fixed point set of $\tau_d$ restricted to $\mathfrak{z}_\sigma$. Set $\epsilon = 1$ if $\mathfrak{z}_{\tau_d}$ lies in the same component as $\mathfrak{z}_\sigma \cap t$ and $\epsilon = -1$ otherwise. Then, since $a_\sigma$ is an inner automorphism of $m_{\sigma,1}$, we know that $l_{d,\sigma} \in \mathcal{L}(S_\sigma, \epsilon, d|_{S_\sigma})$.

**Example 4.2** When $\sigma(\alpha) = 0$ for all $\alpha$, we have $l_{d,\sigma} = \mathfrak{h}_{\tau_d} + \mathfrak{n}$. On the other hand, $\sigma$ is a $d$-signature if and only if $l_{d,\sigma}$ is a real form of $\mathfrak{g}$. In this case, $l_{d,\sigma} \in \mathcal{L}(\mathfrak{g}, d)$.

We choose $H \in \mathfrak{h}$ such that $\alpha(H) > 0$ if $\alpha$ is a root of $\mathfrak{n}_\sigma$ and $\alpha(H) = 0$ if $\alpha$ is a root of $m_{\sigma,1}$. Choose a $d$-signature $\sigma'$ such that $\sigma'(\alpha) = \sigma(\alpha)$ if $\sigma(\alpha) \neq 0$. Then by writing down generators of $l_{d,\sigma'}$, one can check that

$$\lim_{t \to +\infty} \exp(tH)l_{d,\sigma'} = l_{d,\sigma},$$

where the limit takes place in the Grassmannian $\text{Gr}(n, \mathfrak{g})$. It follows that $l_{d,\sigma} \in \mathcal{L}(\mathfrak{g}, d)$. 

29
4.2 Extended signatures and real forms

To relate real forms to signatures, we recall some standard results concerning real forms (see [A-B-V], Chapter Two). Recall

\[ G^{-\tau_d} = \{ x \in G : \tau_d(x) = x^{-1} \} . \]

Note that \( G \) acts on \( G^{-\tau_d} \) by

\[ g \triangleright x = gx\tau_d(g^{-1}) \]

It is routine to check that if \( \tau = \text{Ad}_x\tau_d \) is an involution, then

\[ \text{Ad}_g\text{Ad}_x\tau_d\text{Ad}_g^{-1} = \text{Ad}_{g^2}\tau_d \]

**Lemma 4.3** If \( x \in G^{-\tau_d} \), there exists \( g \in G \) such that \( g \triangleright x = t \in T^{\tau_d} \) is of order 2.

**Proof.** Since \( x \in G^{-\tau_d} \), \( \text{Ad}_x\tau_d \) is an involution. By conjugating in \( G \), we may assume \( \text{Ad}_x\tau_d \) and \( \theta \) commute (see [He], Theorem III.7.1 and following remark). It follows that \( x \in K \). By [Ka], there exists \( u \in K \) such that \( u \triangleright x \in T^{\tau_d} \), so \( u \triangleright x \in T^{\tau_d} \) since \( \theta \) acts trivially on \( T \). But \( u \triangleright x \in G^{-\tau_d} \), so \( u \triangleright x = (u \triangleright x)^{-1} \), and hence \( u \triangleright x \) is of order two.

\[ \text{Q.E.D.} \]

**Lemma 4.4** Any \( t \in \mathcal{L}(g, d) \) is \( G \)-conjugate to a real form \( t_{d, \sigma} \) for some \( d \)-signature \( \sigma \).

**Proof.** We know any real form in \( \mathcal{L}(g, d) \) is of of the form \( \text{Ad}_g\tau_d \) with \( g \in G^{-\tau_d} \), so by the previous lemma, by \( G \)-conjugation it can be put in the form \( \text{Ad}_t\tau_d \) for some \( t \in T^{\tau_d} \) of order 2. Since \( t \) is of order 2, the eigenvalue \( \sigma_t(\alpha) \) of \( t \) on \( g_\alpha \) is \( \pm 1 \). It is easy to check that \( \sigma_t \) is a signature, and since \( t \in T^{\tau_d} \), it is a \( d \)-signature. Hence our real form is conjugate to \( \sigma_t\tau_d \).

\[ \text{Q.E.D.} \]
4.3 The $G$-orbit of $\mathfrak{l}_{d,\sigma}$

Let $\sigma$ be an extended $d$-signature $\sigma$ with $\text{supp}(\sigma) = [S_\sigma]$. We will use $L_{d,\sigma}, M_\sigma, P_\sigma$ and $N_\sigma$ to denote the connected subgroups of $G$ with Lie algebras $\mathfrak{l}_{d,\sigma}, \mathfrak{m}_\sigma, \mathfrak{p}_\sigma$ and $\mathfrak{n}_\sigma$ respectively. Recall also that $\mathfrak{z}_\sigma = \mathfrak{z}_{S_\sigma}$.

Lemma 4.5

$$\dim_{\mathbb{R}} G \cdot \mathfrak{l}_{d,\sigma} = \dim_{\mathbb{C}} \mathfrak{g} - \dim_{\mathbb{C}} \mathfrak{z}_\sigma.$$  

Proof. This follows from Lemma 3.7.

Q.E.D.

Lemma 4.6  Let $\sigma$ be an extended $d$-signature with $d$ trivial. Then $G \cdot \mathfrak{l}_{d,\sigma} = K \cdot A \cdot \mathfrak{l}_{d,\sigma}$.

Proof. Since $K$ acts transitively on $G/P_\sigma$ and $P_\sigma$ has Levi decomposition $P_\sigma = M_\sigma N_\sigma$, we can write $g = kmn, k \in K, m \in M_\sigma, n \in N_\sigma$. For any real reductive group $G$ and the fixed point subgroup $G_0$ of an involution, there is a Cartan decomposition $G = K \tilde{A} G_0$ where $\tilde{A}$ is chosen so that its Lie algebra $\tilde{\mathfrak{a}}$ has maximal intersection with $\mathfrak{g}^{-\sigma,-\theta}$, the subspace of $\mathfrak{g}$ on which $\sigma$ and $\theta$ act as $-1$ (see [Ro], Theorem 10). When $d$ is trivial, any real form $G_0$ in $L(\mathfrak{g},d)$ contains a Cartan subalgebra of $\mathfrak{t}$, so up to $K$-conjugacy we can choose $\tilde{\mathfrak{a}} = \mathfrak{a} = i\mathfrak{t}$ so we can take $\tilde{A} = A$, the Iwasawa factor. By the Cartan decomposition applied to the group $M_\sigma$, we can write $m = kmx, m \in M_\sigma \cap K$, $a \in A, x \in M_\sigma^\theta$. Thus, we can write $g = k_1 au$, with $k_1 \in K, a \in A, u \in L_{d,\sigma}$.

Q.E.D.

5 \linebreak \underline{$\mathcal{L}(\mathfrak{g},d)$ as the real part of the De Concini-Procesi compactification $Z_d$ of $G$}

In this section, we identify the variety $\overline{\mathcal{L}(\mathfrak{g},d)}$ with the real points of a De Concini-Procesi compactification $Z_d$ of the group $G$. Since $Z_d$ is known to be smooth, it follows that $\overline{\mathcal{L}(\mathfrak{g},d)}$ is a manifold. We also show that $\overline{\mathcal{L}(\mathfrak{g},d)}$ is connected and determine the $G$-orbits in $\overline{\mathcal{L}(\mathfrak{g},d)}$. 

31
5.1 The complexification of $\mathfrak{g}$

Regard $\mathfrak{g}$ as a real Lie algebra and denote its complex structure by $J_0 \in \text{End}_\mathbb{R}(\mathfrak{g})$. We may identify its complexification $\mathfrak{g}_\mathbb{C}$ with $(\mathfrak{g} \oplus \mathfrak{g}, J_0 \oplus J_0)$ via the map

$$\mathfrak{g}_\mathbb{C} \rightarrow (\mathfrak{g} \oplus \mathfrak{g}, J_0 \oplus J_0) : x + iy \mapsto (x + J_0 y, \theta(x) + J_0 \theta(y)), \ x, y \in \mathfrak{g}.$$ 

Under this identification, the complex conjugation operator $\tau$ on $\mathfrak{g}_\mathbb{C}$ becomes

$$\tau(X, Y) = (\theta(Y), \theta(X)),$$

with its set of real points realized as

$$(\mathfrak{g} \oplus \mathfrak{g})^\tau = \{(X, \theta(X)) : X \in \mathfrak{g}\}.$$

If $\mathfrak{r} \subset \mathfrak{g}$ is a real subalgebra, then $\mathfrak{r}_\mathbb{C} = \mathfrak{r} + i\mathfrak{r}$ is regarded as a complex subalgebra of $\mathfrak{g} \oplus \mathfrak{g}$. For example, $\mathfrak{r}_\mathbb{C}$ is the diagonal subalgebra $\mathfrak{g}_\Delta = \{(X, X) : X \in \mathfrak{g}\}$ and $(t + n_+)_\mathbb{C} = \mathfrak{h}_\Delta + n_1 + n_{-2}$, where for a Lie subalgebra $\mathfrak{r}$ of $\mathfrak{g}$,

$$\mathfrak{r}_\Delta = \{(X, X) : X \in \mathfrak{r}\}, \ \mathfrak{r}_1 = \{(x, 0) : x \in \mathfrak{r}\}, \ \mathfrak{r}_2 = \{(0, x) : x \in \mathfrak{r}\}. \quad (15)$$

The proof of the following lemma is straightforward.

**Lemma 5.1** For an extended $d$-signature $\sigma$, the complexification $\mathfrak{l}_{d, \sigma, \mathbb{C}}$ of $\mathfrak{l}_{d, \sigma}$ is

$$\mathfrak{l}_{d, \sigma, \mathbb{C}} = \{(X, a_\sigma \gamma_d(X)) : X \in \mathfrak{m}_\sigma\} \oplus n_{\sigma_1} \oplus n_{\sigma_{-2}}$$

Recall that $\ll, \gg$ is the Killing form of $\mathfrak{g}$. Consider the symmetric form $I$ on $\mathfrak{g} \oplus \mathfrak{g}$ given by

$$I((x_1, x_2), (y_1, y_2)) = \ll x_1, y_1 \gg - \ll x_2, y_2 \gg.$$

Then $\mathfrak{t} \subset \mathfrak{g}$ is a real Lagrangian subalgebra of $\mathfrak{g}$ with respect to the imaginary part of the Killing form if and only if $\mathfrak{t}_\mathbb{C} \subset \mathfrak{g} \oplus \mathfrak{g}$ is a complex Lagrangian subalgebra with respect to $I$.

If we denote by $\mathcal{L}_\mathbb{C}$ the set of all complex Lagrangian subalgebras of $\mathfrak{g} \oplus \mathfrak{g}$ with respect to $I$, then we have the injective map

$$\mathcal{L} \rightarrow \mathcal{L}_\mathbb{C} : \mathfrak{t} \mapsto \mathfrak{t}_\mathbb{C}.$$
With respect to the Adjoint action of $G$ on $L$, we have

$$(\text{Ad}_g)_{\mathcal{C}} = \text{Ad}_{(g, \theta(g))}(l_{\mathcal{C}}).$$

On the group level, we have the analogous identification $G_{\mathcal{C}} \simeq G \times G$. We lift $\tau$ to an involution also denoted $\tau$ of $G \times G$. In this context, $G$ (as the set of real points) is identified with the fixed point set of $\tau$ as

$$\{(g, \theta(g)) : g \in G\}$$

Let $G_{\Delta, d} = \{(x, \gamma_d(x)) : x \in G\}$. Then $(G \times G)/G_{\Delta, d}$ is an example of a complex symmetric space, and De Concini and Procesi [D-P] have exhibited a particular smooth compactification $Z_d$ of $(G \times G)/G_{\Delta, d}$.

### 5.2 The De Concini-Procesi compactification $Z_d$

Note that $G \times G$ acts on the Grassmannian of $n$-dimensional complex subspaces of $\mathfrak{g} \oplus \mathfrak{g}$ through the Adjoint action, where $n = \text{dim}_{\mathbb{C}} \mathfrak{g}$. Consider the $\gamma_d$-diagonal subalgebra

$$\mathfrak{g}_{\Delta, d} = \{(X, \gamma_d(X)) : X \in \mathfrak{g}\}$$

of $\mathfrak{g} \oplus \mathfrak{g}$ and the orbit $(G \times G) \cdot \mathfrak{g}_{\Delta, d}$ inside the Grassmannian. The stabilizer subgroup of $G \times G$ at $\mathfrak{g}_{\Delta, d}$ is $G_{\Delta, d}$, so $(G \times G) \cdot \mathfrak{g}_{\Delta, d} \simeq (G \times G)/G_{\Delta, d}$. By definition, the De Concini-Procesi variety is the closure (with respect to the Zariski or the classical topology) of $(G \times G) \cdot \mathfrak{g}_{\Delta, d}$ in the Grassmannian. It will be denoted by $Z_d$ and it is called the De Concini-Procesi compactification (of $(G \times G)/G_{\Delta, d}$). It is a smooth complex manifold of complex dimension $n$ (see [D-P] for more details). Since the variety of complex Lagrangian subalgebras is $G \times G$ stable, it follows that every element in $Z_d$ is a complex Lagrangian subalgebra of $\mathfrak{g} \oplus \mathfrak{g}$ of dimension $n$.

It is known [D-P] that $G \times G$ has finitely many orbits on $Z_d$. We describe the orbits. Recall that $S(\Sigma_+) = \{\alpha_1, \ldots, \alpha_l\}$ is the set of all simple roots. Let $\eta : S(\Sigma_+) \to \{0, 1\}$ be any map. Regarding $\eta$ as an extended signature for the trivial involution, we have the parabolic subalgebra

$$\mathfrak{p}_\eta = \mathfrak{m}_\eta + \mathfrak{n}_\eta$$

and $\mathfrak{n}_{\eta -} = \theta(\mathfrak{n}_\eta)$ of $\mathfrak{g}$. Consider the subalgebra

$$\mathfrak{g}_{d, \eta} = \{(X, \gamma_d(X)) : X \in \mathfrak{m}_\eta\} \oplus \mathfrak{n}_{\eta 1} \oplus \gamma_d \mathfrak{n}_{\eta -2}.$$
Note that when \( \eta \) is constant on \( d \)-orbits and is regarded as an extended \( d \)-signature, we have \( \mathfrak{g}_{d,\eta} = \mathfrak{t}_{d,\eta,\mathbb{C}} \).

**Theorem 5.2** [D-P] Every point \( r \in Z_d \) is in a \( G \times G \) orbit of \( \mathfrak{g}_{d,\eta} \) for some \( \eta \).

We say that a complex subalgebra \( r \) of \( \mathfrak{g} \oplus \mathfrak{g} \) has a real structure if it is the complexification of a real subalgebra of \( \mathfrak{g} \) under the identification \( \mathfrak{g}_{\mathbb{C}} \cong \mathfrak{g} \oplus \mathfrak{g} \). This is equivalent to the condition that \( \tau(r) = r \), and in this case,

\[
r = (r^\tau)_{\mathbb{C}},
\]

where \( r^\tau \subset \mathfrak{g} \oplus \mathfrak{g} \), the fixed point set of \( \tau \) in \( r \), is identified with its image in \( \mathfrak{g} \) under the projection \( \mathfrak{g} \oplus \mathfrak{g} \to \mathfrak{g} : (x, y) \mapsto y \).

**Notation 5.3** We will denote the set of all Lie algebras in \( Z_d \) with a real structure by \( Z_d,_{\mathbb{R}} \).

Note that \( \mathfrak{g}_{\Delta,d} \in Z_{d,\mathbb{R}} \). In fact,

\[
\mathfrak{g}_{\Delta,d} = (\mathfrak{u}_{\sigma_1})_{\mathbb{C}},
\]

where \( \sigma_1(\alpha) = 1 \) for all \( \alpha \).

In fact, \( \mathfrak{g}_{d,\eta} \) is in \( Z_{d,\mathbb{R}} \) if and only if \( \eta \) is constant on \( d \)-orbits.

Since \( \tau \) preserves \( \mathfrak{g}_{\Delta,d} \), \( \tau \) preserves the open subset \((G \times G) \cdot \mathfrak{g}_{\Delta,d} \subset Z_d \). Since \( \tau \) is continuous, it follows that \( \tau \) preserves \( Z_d \). Thus, \( Z_{d,\mathbb{R}} \) is the set of real points of a complex compact manifold, so \( Z_{d,\mathbb{R}} \) is a compact manifold.

### 5.3 \( G \)-orbits on \( Z_{d,\mathbb{R}} \)

Recall that for every Lagrangian subalgebra \( \mathfrak{t} \subset \mathfrak{g} \),

\[
(\text{Ad}_{g}(\mathfrak{t}))_{\mathbb{C}} = (\text{Ad}_{g}, \text{Ad}_{\theta(g)})(\mathfrak{t}_{\mathbb{C}}), \quad \forall g \in G.
\] (16)

**Proposition 5.4** Every \( r \in Z_{d,\mathbb{R}} \) is \( G \)-conjugate to \( \mathfrak{t}_{d,\sigma,\mathbb{C}} \) for some extended \( d \)-signature \( \sigma \).
Proof. Let \( r = (g_1, g_2) \cdot g_{d,\eta} \) for some \( \eta \), so

\[
r = \{ (\Ad_{g_1}(y + z_1), \Ad_{g_2}\gamma_d(y + z_2)) : y \in m_\eta, z_1 \in n_\eta, z_2 \in n_{\eta-} \}.
\]

Since \( r \) has a real structure, \( \tau(r) = r \), so

\[
(\Ad_{\theta(g_2)}\gamma_d(y + z_2), \Ad_{\theta(g_1)}\theta(y + z_1))
\]

is in \( r \), so that \( \Ad_{\theta(g_2)}\gamma_d(y + z_2) = \Ad_{g_1}(u + v_1) \) for some \( u \in m_\eta \) and \( v_1 \in n_\eta \). But

\[
p_\eta = \{ \theta(y + z_2) : y \in m_\eta, z_2 \in n_{\eta-} \},
\]

so \( \Ad_{g_1^{-1}}\gamma_d(p_\eta) \subset p_\eta \). Since \( \gamma_d(p_\eta) \) is \( G \)-conjugate to \( p_\eta \), it follows that \( \gamma_d(p_\eta) = p_\eta \). Since \( P_\eta \) is the normalizer of \( p_\eta \), it follows that \( g_1^{-1}\theta(g_2) \in P_\eta \), so \( g_2 = \theta(g_1p) \), for some \( p \in P_\eta \). Thus,

\[
r = \{ (\Ad_{g_1}(y + z_1), \Ad_{\theta(g_1)}(p_\eta)\gamma_d(y + z_2)) : y \in m_\eta, z_1 \in n_\eta, z_2 \in n_{\eta-} \}.
\]

Thus, up to \( G \)-conjugacy,

\[
r = \{ (y + z_1), \Ad_{\theta(p)}\gamma_d(y + z_2)) : y \in m_\eta, z_1 \in n_\eta, z_2 \in n_{\eta-} \}
\]

and \( m_\eta \), \( n_\eta \) and \( n_{\eta-} \) are \( \gamma_d \)-stable.

We write \( \theta(p) = lu \) with \( l \in M_\eta \), \( u \in N_{\eta-} \). Since

\[
\{ u \cdot (y + z_2) : y \in m_\eta, z_2 \in n_{\eta-} \} = \{ (y + w_2) : y \in m_\eta, w_2 \in n_{\eta-} \}
\]

it follows that

\[
r = \{ ((y + z_1), \Ad_l\gamma_d(y + z_2)) : y \in m_\eta, z_1 \in n_\eta, z_2 \in n_{\eta-} \}.
\]

We use again the assumption that \( r \) has a real structure and the facts that \( \theta(m_\eta) = m_\eta \),

\( \theta(n_\eta) = n_{\eta-} \), \( M_\eta \) preserves the decompositions \( p_\eta = m_\eta + n_\eta \) and \( \theta(p_\eta) = m_\eta + n_{\eta-} \). Since

\[
\tau(y + z_1, \Ad_l\gamma_d(y + z_2)) = (\Ad_{\theta(l)}\gamma_d(y + \theta(z_2)), \theta(y) + \theta(z_1)),
\]

we see that

\[
\{ \Ad_{\theta(l)}\gamma_d(y) : y \in m_\eta \} = \{ (y, \Ad_l\gamma_d(y)) : y \in m_\eta \} = \{ (\gamma_d(\Ad_{l^{-1}}y), y) : y \in m_\eta \}.
\]

35
Hence, \( \text{Ad}_{\theta(l)} \gamma_d = \gamma_d \text{Ad}_{l^{-1}} \), and it follows that \( \tau_d(l) = l^{-1} \).

Now, by Lemma 4.3, there exists \( v \in M_\eta \) such that \( v \star l = t \in T^\gamma_d \) of order 2. But it is easy to check that

\[
(\theta(v), v) \cdot (1, l) \cdot g_{d,\eta} = (1, v \star l) g_{d,\eta}.
\]

Hence, after acting by an element of \( M_\eta \), we may assume that \( t = (1, t) \cdot g_{d,\eta} \) and that \( t \in T^\gamma_d \) is an element of order 2.

As before, let \( \sigma_t(\alpha) \) be the eigenvalue of \( t \) on the root space \( g_\alpha \). Then \( \sigma_t \) is a \( d \)-signature and we can define a new extended \( d \)-signature \( \sigma' \) by

\[
\sigma'(\alpha) = \eta(\alpha) \sigma_t(\alpha)
\]

Then \( (1, t) \cdot g_{d,\eta} = t_{d,\sigma',C} \), using Lemma 5.1, which completes the proof of the proposition.

Q.E.D.

5.4 Geometry and topology of the closure \( \overline{L(g, d)} \)

Theorem 5.5 \( Z_{d,R} \) is connected.

Proof. Since \( G \) is connected, Proposition 5.4 implies that it suffices to find a path from \( t_{d,\sigma,C} \) to the solvable Lie algebra \( t_{d,\sigma_0,C} \), where \( \sigma_0(\alpha) = 0 \) for all \( \alpha \in \Sigma \). Note that

\[
t_{d,\sigma_0,C} = \{(H, \gamma_d(H)) : H \in \mathfrak{h}\} \oplus n_1 \oplus n_{-2}.
\]

Let \( H \in \mathfrak{h} \) have the property that \( \alpha(H) > 0 \) for all \( \alpha \in \Sigma_+ \). If \( X \in m_\sigma \cap g_\alpha, \alpha \in \Sigma_+ \), then

\[
\lim_{t \to +\infty} (\text{Ad}_{\exp(tH)} \cdot \text{Ad}_{\theta(\exp(tH))}) C(X, \gamma_d(X)) = C(X, 0),
\]

and if \( X \in m_\sigma \cap g_\alpha, \alpha \in -\Sigma_+ \),

\[
\lim_{t \to +\infty} (\text{Ad}_{\exp(tH)} \cdot \text{Ad}_{\theta(\exp(tH))}) C(X, \gamma_d(X)) = C(0, \gamma_d(X)).
\]

Since

\[
t_{d,\sigma,C} = \{(X, \gamma_d(X)) : X \in m_\sigma\} \oplus n_{\sigma 1} \oplus n_{\sigma -2},
\]

it follows that

\[
\lim_{t \to +\infty} (\text{Ad}_{\exp(tH)} \cdot \theta(\exp(tH))) t_{d,\sigma,C} = t_{d,\sigma_0,C}.
\]
**Remark 5.6** This theorem can also be proved by observing that \( Z_{d,\mathbb{R}} \) has a unique closed \( G \)-orbit \( G \cdot t_{d,\sigma,\mathbb{C}} \). The Lie algebra \( t_{d,\sigma,\mathbb{C}} = h^{\tau_d} + n \). When \( d \) is non-trivial, and \( \sigma \) is a \( d \)-signature, the curve \( \exp(ad_{tH}) t_{d,\sigma} \) provides a class of examples when \( T : \mathcal{L} \to \mathcal{L} \) is not continuous (see Remark 2.21).

**Notation 5.7** We will use \( Z_{d,\eta} \) to denote the \( G \times G \)-orbit through \( g_{d,\eta} \). We let \( \eta_1 \) be the extended \( d \)-signature such that \( \eta_1(\alpha_i) = 1 \), all \( \alpha_i \in S(\Sigma_+). \) Then \( g_{d,\eta_1} = g_{\Delta,d} \), and \( Z_{d,\eta_1} \) is the unique open \( G \times G \) orbit in \( Z_d \).

**Theorem 5.8**

\[
\mathcal{L}(g, d) \cong Z_{d,\mathbb{R}}
\]

under the complexification map \( t \to t_{\mathbb{C}} \). In particular, \( \mathcal{L}(g, d) \) is a smooth manifold.

**Proof.** By Proposition 5.4, we know \( G \) has finitely many orbits on \( Z_{d,\mathbb{R}} \), and the orbits are given by extended \( d \)-signatures. The open orbits are given by the orbits through \( t_{d,\sigma,\mathbb{C}} \), where \( \sigma \) is a \( d \)-signature. Indeed, in the proof of Proposition 5.4, we showed that \( Z_{d,\eta} \cap Z_{d,\mathbb{R}} \) is a finite disjoint union of \( G \)-orbits \( G \cdot t_{d,\sigma,\mathbb{C}} \) with \( |\sigma(\alpha)| = \eta(\alpha) \) for every root \( \alpha \). Moreover, each of these \( G \)-orbits has the same dimension by Lemma 4.3. It follows that the orbits \( G \cdot t_{d,\sigma,\mathbb{C}} \) are the connected components of \( Z_{d,\eta} \cap Z_{d,\mathbb{R}} \) for \( \eta = |\sigma| \) and also that the \( G \cdot t_{d,\sigma,\mathbb{C}} \) are locally closed. Since \( Z_{d,\eta_1} \) is open, the orbits \( G \cdot t_{d,\sigma,\mathbb{C}} \) are open when \( \sigma \) is a \( d \)-signature, and by the dimension statement, none of the other orbits are open since \( Z_{d,\mathbb{R}} \) is connected. Moreover, it follows from the fact that \( Z_{d,\mathbb{R}} \) is a finite union of locally closed orbits that the union of the open orbits is dense.

Now it suffices to prove that \( \mathcal{L}(g, d) \) surjects onto the open orbits of \( Z_{d,\mathbb{R}} \). By Lemma 4.4, we know that every real form in \( \mathcal{L}(g, d) \) is \( \Ad g t_{d,\sigma} \), for some \( d \)-signature \( \sigma \). It follows from (16) and the above description of open orbits on \( Z_{d,\mathbb{R}} \) that \( \mathcal{L}(g, d) \) maps onto the union of the open orbits of \( Z_{d,\mathbb{R}} \).

Q.E.D.
Lemma 5.9  The Zariski closure of $\mathcal{L}(g, d)$ coincides with its closure in the classical topology.

Proof.  We know 

$$\mathcal{L}(g, d) = \bigcup_{\sigma} G \cdot \mathfrak{l}_{d, \sigma} = Z_{d, m} \cap Z_{d, R},$$

where the union is over all $d$-signatures and $Z_{d, m}$ is the open $G \times G$ orbit on $Z_d$. Thus, $\mathcal{L}(g, d)$ is the real points of $Z_{d, m}$. But the Zariski closure of the real points is contained in the real points of the Zariski closure, so the Zariski closure of $\mathcal{L}(g, d)$ is contained in $Z_{d, R} = \overline{\mathcal{L}(g, d)}$. Since the classical closure of $\mathcal{L}(g, d)$ is contained in the Zariski closure, it follows that they coincide.

Q.E.D.

5.5  Open orbits in $\overline{\mathcal{L}(g, d)}$

In this subsection we identify the open orbits in $Z_{d, R}$ with symmetric spaces.

Proposition 5.10  Let $\tau$ be a real form of a semisimple Lie algebra $g$, and also denote its lifting to the adjoint group $G$ by $\tau$. Then

$$G^\tau = N_G(\mathfrak{g}^\tau).$$

(see [D-P] for the holomorphic version of this fact. The proof is essentially the same).

Corollary 5.11  For a $d$-signature $\sigma$, the open orbit $G \cdot \mathfrak{l}_{d, \sigma, C}$ is the semisimple symmetric space $G/G^{\tau_{d, \sigma}}$.

Proof.  The above proposition implies that the stabilizer $N_G(\mathfrak{l}_{d, \sigma}) = G^{\tau_{d, \sigma}}$.

Q.E.D.
5.6 Another description for $L(g, id)$

The set $L(g, id)$ has been most important for applications. In this section, we give another description of it.

When the diagram automorphism $d$ is trivial, we will refer to the corresponding real De Concini-Procesi compactification as $Z_R$ instead of $Z_{d,R}$. By Theorem 5.8, $Z_R = L(g, id)$. It will follow from the description of irreducible components in Section 6.2 that $Z_R$ is the unique irreducible component of $L$ containing $t$. We let

$$L_0 = \{ l \in L : \text{rank}(t \cap l) = \text{rank}(t) \}.$$  

It is the set of Lagrangian subalgebras of $L$ containing the Lie algebra of a maximal torus of $t$.

**Proposition 5.12** $L_0 = Z_R$.

**Proof.** Write $t_\sigma$ for $t_{d,\sigma}$ for $d$ trivial. First assume $l = Ad_g t_{d,\sigma}$ lies in $Z_R$. By Lemma 4.6, we can write $l = Ad_k t_{d} t_\sigma$, for $k \in K$, $a \in A$. But $t_\sigma$ contains $t$, so $Ad_k t_{d} t_\sigma$ contains $Ad_k(t)$, since $A$ acts trivially on $t$. Thus, $l \in L_0$.

Now assume a Lagrangian subalgebra $l$ contains the Lie algebra of a maximal torus of $K$. By $[K a]$, we know $t = Ad_k (m^r_{s,1} \oplus V \oplus n_S)$, for some $(S, V, \tau)$. By the assumption on $l$, we may assume that $m^r_{s,1} \oplus V$ contains $t$. Then $V = t \cap m_{s}^r$ and $m^r_{s,1}$ contains a Cartan subalgebra of $m_{s,1} \cap t$. But it is easy to show that if $\tau$ does not have trivial diagram automorphism, then $m^r_{s,1}$ does not contain a Cartan subalgebra of $m_{s,1} \cap t$. It follows easily that $l \in Z_R$.

Q.E.D.

We remark that it follows that $G$ acts on $L_0$, a fact that is not clear from the definition of $L_0$.

**Corollary 5.13** All points of $Z_R$ are model points.

**Proof.** This follows from Proposition 5.12 and the observation that if $l(S, V, \tau)$ contains $t$, then $V \subset t$. 

39
Remark 5.14 It follows from Corollary 5.13 that many familiar Poisson structures
are contained in $Z_{\mathbb{R}}$ as $G$ or $K$ orbits with the Poisson structures being the restriction
of the Poisson structure $\Pi$ on $\mathcal{L}$ defined in Section 2.2. For example, we can identify
$G \cdot \mathfrak{t} \cong G/K$, and the Poisson structure induced by $\Pi$ on $G/K \cong \mathcal{N}$ is the negative
of the Poisson structure $\pi_{\mathcal{N}}$ that makes $\mathcal{N}$ into the dual Poisson Lie group of $K$.
More generally, by looking at $G$-orbits in $\mathcal{L}(g,d)$, we obtain in this manner a Poisson
structure on $G/G_0$ for every real form $G_0$ of $G$. The Poisson manifolds arising from
$K$-orbits in $Z_{\mathbb{R}}$ are studied in more detail in Section 7.

Remark 5.15 Not all points in $Z_{d,\mathbb{R}}$ are model points when $d$ is not trivial. The
criterion for $t_{d,\sigma}$ to be a model point is that if $\sigma(\alpha) = 0$, then $d(\alpha) = \alpha$.

In [E-L], we introduced certain $K$-invariant metrics $g_\lambda$ on $T^*(K/T)$ for $\lambda \in \mathfrak{a}_r$,
the set of elements in $\mathfrak{a}$ whose centralizer in $K$ is $T$. These metrics are important for
showing that an operator $S$ introduced by Kostant is a limit of some Hodge Laplacians
$S_\lambda$. The existence of this family simplifies the proof of Kostant’s basic result that $\text{Ker}(S)$
is isomorphic to $H^*(K/T)$. We remark that the metrics $g_\lambda$ can be understood in terms
of the restriction of a Riemannian metric on the Riemannian symmetric space $G/K$.
Since $Z_{\mathbb{R}}$ is a compactification of $G/K$ with closed orbit the flag manifold $G/B$, this
observation provides evidence that embedding the Bruhat-Poisson structure on $G/B$
into the manifold $Z_{\mathbb{R}}$ is useful in Poisson geometry.

We give the construction of this metric. We can identify the tangent space of $G/K$
at $gK$ with $\text{Ad}_g(\mathfrak{i}\mathfrak{t})$. The Killing form is positive definite at $\text{Ad}_g(\mathfrak{i}\mathfrak{t})$, and we let $s$
be the metric on $G/K$ given by taking the square root of the Killing form metric on $\text{Ad}_g(\mathfrak{i}\mathfrak{t})$.

Let $H_\lambda \in \mathfrak{a}$ be such that $\lambda(H) = (H_\lambda, H)$ and let $a_\lambda = \exp(H_\lambda)$. Then the $K$-orbit
through $a_\lambda K \in G/K$ can be identified with $K/T$. If we restrict the above metric $s$
to a metric $s_\lambda$ on $K \cdot a_\lambda K \subset G/K$, and use $s_\lambda$ to identify the cotangent bundle with the
tangent bundle, then one can show by easy calculations that we obtain the metric $g_\lambda$
from [E-L].
6  Geometry of $\mathcal{L}(S, \epsilon, d)$

In this section, we combine results from Section 3 with results from Section 5 to study the closures $\mathcal{L}(S, \epsilon, d)$.

6.1  Smoothness of $\mathcal{L}(S, \epsilon, d)$

Theorem 6.1  Each $\mathcal{L}(S, \epsilon, d)$ is a smooth connected submanifold of the Grassmannian $\text{Gr}(n, g)$ of dimension $\dim(k) + \frac{z(z-3)}{2}$. It fibers over $G/P_s$ with the fiber being the product of $\mathcal{L}_{3S, \epsilon}$ with $\mathcal{L}(m_{2,1}, d)$, the real points of a De Concini-Procesi variety.

Proof.  Recall from the proof of Proposition 3.13 that

$$\mathcal{L}_{p_S}(S, \epsilon, d) \cong \mathcal{L}_{3S, \epsilon} \times \mathcal{L}(m_{s,1}, d)$$

Thus,

$$\mathcal{L}_{p_S}(S, \epsilon, d) \cong \mathcal{L}_{3S, \epsilon} \times \mathcal{L}(m_{s,1}, d)$$

because $\mathcal{L}_{3S, \epsilon}$ is already closed. Once we identify $K \times_{K \cap P_S} \mathcal{L}_{p_S}(S, \epsilon, d) \cong \mathcal{L}(S, \epsilon, d)$ the theorem will follow from Theorem 5.8, Theorem 5.5, and Proposition 3.4.

So we consider the map

$$m : K \times_{K \cap P_S} \mathcal{L}_{p_S}(S, \epsilon, d) \rightarrow \mathcal{L}(S, \epsilon, d)$$

given by $m(k, t) = Ad_k t$. It is easy to see that Karolinsky’s Theorem 3.2 implies that $m$ is onto. It suffices to check that $m$ is an immersion, since $m$ is clearly smooth and proper. To show $m$ is injective, suppose that for $i = 1, 2$, $t(S_i, V_i, \tau_i) \in \mathcal{L}_{p_S}(S, \epsilon, d)$ and $Ad_k t(S_i, V_i, \tau_i) = Ad_k t(S_2, V_2, \tau_2)$. It follows as in the proof of Proposition 3.3 that $S_1 = S_2$ and $k_1^{-1}k_2 \in K \cap P_{S_1}$. Note that $n_s \subset n_{S_1}$, so $P_{S_1} \subset P_s$. It follows easily that $m$ is injective, and the proof that the tangent map $m_*$ is injective is similar to the proof of the same fact in Proposition 3.13.

The dimension statement is clear from Proposition 3.13.

Q.E.D.
6.2 Irreducible components

In this subsection we determine the irreducible components of $\mathcal{L}$.

**Proposition 6.2** $\overline{\mathcal{L}(S, \epsilon, d)}$ is Zariski closed and irreducible.

**Proof.** Since $\overline{\mathcal{L}(m_{S,1}, d) \times L_{3S,\epsilon}}$ is Zariski closed in $\text{Gr}(n, g)$ via the embedding $(t, V) \to t + V + n_S$ (Proposition 3.4 and Lemma 5.9), it follows that $G \times_{P_S} (\overline{\mathcal{L}(m_{S,1}, d) \times L_{3S,\epsilon}}) \times \text{Gr}(n, g)$. Moreover, the map $m : G \times_{P_S} (\overline{\mathcal{L}(m_{S,1}, d) \times L_{3S,\epsilon}}) \to \text{Gr}(n, g)$ is projective, so its image is Zariski closed, and irreducible since the domain is irreducible. Thus, the proposition follows from Theorem 6.1.

Q.E.D.

**Definition 6.3** Lagrangian data $(S, \epsilon, d)$ is said to be inessential if $S = S(\Sigma_+) - \{\alpha_i\}$, $d = d'|_S$ for some diagram automorphism $d'$ of $S(\Sigma_+)$, and $\epsilon = 1$. Otherwise, $(S, \epsilon, d)$ is called essential.

**Proposition 6.4** Lagrangian data $(S, \epsilon, d)$ is inessential if and only if $\mathcal{L}(S, \epsilon, d) \subset \partial \mathcal{L}(S', \epsilon', d')$ for some Lagrangian data $(S', \epsilon', d')$.

**Proof.** If $(S, \epsilon, d)$ is inessential, then we claim $\mathcal{L}(S, \epsilon, d) \subset \overline{\mathcal{L}(S(\Sigma_+), 1, d')}$. Indeed, since $\text{dim}(z_S) = 1$ and $\epsilon = 1$, the Lagrangian subspace $V$ in $z_S$ is $z_S \cap t$. It follows from Theorem 3.2 and Lemma 4.4 that each subalgebra in $\mathcal{L}(S, \epsilon, d)$ is $G$-conjugate to $m_{S,1}^{d,\sigma} \oplus z_S \cap t \oplus n_S$ for some $\sigma$. But this algebra coincides with $t^{d,\sigma}$. Hence, $\mathcal{L}(S, \epsilon, d) = \cup_{\sigma} G \cdot t^{d,\sigma}$, so

$$\mathcal{L}(S, \epsilon, d) \subset Z_{d',\mathbb{R}} = \overline{\mathcal{L}(g, d')}.$$ 

Suppose that $\mathcal{L}(S, \epsilon, d) \subset \partial \mathcal{L}(S', \epsilon', d')$. It follows that $S \subset S'$ so $\text{dim}(z_S) > \text{dim}(z_{S'})$. Moreover, by Theorem 6.1, we have

$$\frac{\text{dim}(z_S)(\text{dim}(z_S) - 3)}{2} < \frac{\text{dim}(z_{S'})(\text{dim}(z_{S'}) - 3)}{2}.$$ 

It follows that $\text{dim}(z_S) = 1$ and $\text{dim}(z_{S'}) = 0$. Thus, $\mathcal{L}(S', \epsilon', d') = \overline{\mathcal{L}(g, d')}$ consists of real forms. But $\overline{\mathcal{L}(g, d')} = Z_{d',\mathbb{R}}$, so every subalgebra in $\mathcal{L}(S, \epsilon, d)$ is $G$ conjugate to some $t_{d,\sigma}$ by Proposition 5.4. Since $z_S$ is one-dimensional, and $\gamma_d$ acts by permutations on $\mathfrak{h}$, it follows that $\gamma_d$ acts trivially on $z_S$, so the Lagrangian subalgebra of $z_S$ associated by Karolinsky’s classification with $t_{d,\sigma}$ is $z_S \cap t$. Thus, $t_{d,\sigma} \in \mathcal{L}(S, 1, d'|_S)$, and the assertion follows.
Corollary 6.5

\[ \mathcal{L} = \cup_{\text{essential}(S,\epsilon, d)} \mathcal{L}(S, \epsilon, d) \]

is the decomposition of \( \mathcal{L} \) into irreducible components.

**Proof.** By Proposition 6.2, each \( \mathcal{L}(S, \epsilon, d) \) is irreducible. Thus, the irreducible components are the \( \mathcal{L}(S, \epsilon, d) \) not properly contained in any other \( \mathcal{L}(S', \epsilon', d') \). By the previous Proposition, these correspond to essential data.

Q.E.D.

Corollary 6.6

\[ \mathcal{L}(S(\Sigma_+), 1, \text{id}) \cong \mathcal{L}(g, \text{id}) \cong \mathcal{L}_0 \]

is the only irreducible component of \( \mathcal{L} \) containing \( \mathfrak{t} \).

**Proof.** The Zariski closure of \( G \cdot \mathfrak{t} \) is easily seen to be \( \mathcal{L}(S(\Sigma_+), 1, \text{id}) \), which is not contained in any other irreducible component by the previous Corollary.

Q.E.D.

Note also that \( \mathcal{L} \) itself is typically not smooth, because different irreducible components can intersect. This does not happen for \( \mathfrak{sl}(2) \), but for \( \mathfrak{sl}(3) \), the components \( \mathcal{L}(S(\Sigma_+), 1, \text{id}) \) and \( \mathcal{L}(\emptyset, 1, \text{id}) \) intersect in the flag variety of \( SL(3, \mathbb{C}) \).

7 The Poisson structure \( \Pi \) on \( \mathcal{L} \)

In this section, we study some properties of the Poisson structure \( \Pi \) on \( \mathcal{L} \) defined in Section 2. More specifically, we relate \( \Pi \) to the Bruhat Poisson structure and determine the \( (K, \pi_K) \)-homogeneous Poisson spaces defined by points in \( \mathcal{L}_0 \cong \mathcal{L}(g, \text{id}) \).
7.1 The fibre projection \( \mathcal{L}(S, \epsilon, d) \rightarrow G/P \) is Poisson

It is clear from the definition of \( \Pi \) that every \( G \)-invariant smooth submanifold of \( \mathcal{L} \) is a Poisson submanifold. Thus, each \( \mathcal{L}(S, \epsilon, d) \) is a Poisson submanifold. On the other hand, equip \( G/P \) with the Bruhat Poisson structure \( \pi_\infty \), which is the unique \((K, \pi_K)\)-homogeneous Poisson structure on \( G/P \) that vanishes at the identity coset \( eP \). Recall from Theorem 6.1 that we have the fiber bundle \( \mathcal{L}(S, \epsilon, d) \rightarrow G/P \).

Proposition 7.1 The fiber projection \( \phi \) from \( \mathcal{L}(S, \epsilon, d) \) to \( G/P \) is a Poisson map.

Proof. First, we observe that the projection \( \phi \) is \( G \)-equivariant. Indeed, we can identify \( K \times K \cap P \mathcal{L}_{P_S}(S, \epsilon, d) \) with \( G \times P \mathcal{L}_{P_S}(S, \epsilon, d) \) via the obvious inclusion, and the map from \( G \times P \mathcal{L}_{P_S}(S, \epsilon, d) \) to \( \mathcal{L}(S, \epsilon, d) \) is given by the Adjoint action \((g, t) \mapsto \text{Ad}_g t\). Then the projection to \( G/P \) is given by \((g, t) \mapsto gP \), which is obviously \( G \)-equivariant.

Recall that the Poisson structure on \( \mathcal{L}(S, \epsilon, d) \) is induced by the element \( \frac{1}{2}R \in \wedge^2 g \) given in Section 2.2. Since \( \phi \) is \( G \)-equivariant, it follows that \( \phi_\star \Pi \) is given by the bi-vector field on \( G/P \) induced by \( \frac{1}{2}R \), so we just have to check that \( \frac{1}{2}R \) induces the Bruhat Poisson structure on \( G/P \). It follows from the definition of the Drinfeld map that the Lagrangian subalgebra associated with the point \( eP \) by \( \pi_\infty \) is \((t \cap p_S) \oplus n_S\).

By Theorem 2.22, the Drinfeld map

\[ P : (G/P_S, \pi_\infty) \rightarrow (K \cdot ((t \cap p_S) \oplus n_S), \Pi) \]

is a Poisson map. The normalizer of \((t \cap p_S) \oplus n_S\) in \( K \) is \( K \cap P_S \), and it follows that the Drinfeld map is a diffeomorphism, so \( \pi_\infty \) coincides with \( \Pi \). Since the Poisson structure \( \Pi \) is induced by \( \frac{1}{2}R \), the result follows.

Q.E.D.

7.2 \((K, \pi_K)\)-homogeneous Poisson spaces determined by points in \( \mathcal{L}_0 \)

We now turn to the Poisson submanifold \( (\mathcal{L}_0, \Pi) \), where \( \mathcal{L}_0 \cong \mathcal{L}(g, \text{id}) \) is the unique irreducible component of \( \mathcal{L} \) that contains \( t \). We study the \((K, \pi_K)\)-homogeneous Poisson spaces determined by points in \( \mathcal{L}_0 \) (see Definition 2.9).

By Corollary 5.13, every point in \( \mathcal{L}_0 \) is a model point. It follows from the discussion in Section 2.3 that each \( t \in \mathcal{L}_0 \) can determine a number of \((K, \pi_K)\)-homogeneous Poisson
spaces. Indeed, let $N_K(t)$ be the normalizer subgroup of $t$ in $K$. Then for any subgroup $K_1$ of $K$ with the same Lie algebra $t \cap t$ as $N_K(t)$, the space $K/K_1$ carries a unique Poisson structure $\pi$ such that the covering map

$$P : K/K_1 \longrightarrow K/N_K(t) \cong K \cdot t \subset L_0 : kK_1 \longmapsto kN_K(t)$$

is a Poisson map. The space $(K/K_1, \pi)$ is automatically $(K, \pi_K)$-homogeneous, and the map $P$ is its Drinfeld map (see Definition 2.4). Examples of $K_1$ are $K_1 = N_K(t)$ or $K_1$ is the connected component of the identity of $N_K(t)$. We can characterize these $(K, \pi_K)$-homogeneous Poisson spaces determined by points $t \in L_0$ as follows.

**Proposition 7.2** All $(K, \pi_K)$-homogeneous Poisson spaces $(K/K_1, \pi)$ determined by points in $L_0$ (see Definition 2.4) have the property that $K_1$ contains a maximal torus of $K$. Conversely, all $(K, \pi_K)$-homogeneous Poisson spaces with this property are determined by points in $L_0$.

**Proof.** The first part of the proposition follows from the definition of $L_0$. Now let $(K/K_1, \pi)$ be any $(K, \pi_K)$-homogeneous Poisson space such that $K_1$ contains a maximal torus of $K$. Then the Lie algebra $t_1$ of $K_1$ contains the Lie algebra of a maximal torus of $K$. Consider the Drinfeld map

$$P : K/K_1 \longrightarrow L.$$ 

Let $t = P(eK_1) \in L$. Then by Drinfeld’s Theorem 2.3, $t_1 = t \cap t$ and $K_1 \subset N_K(t)$. Thus $t \in L_0$ by the definition of $L_0$, and $(K/K_1, \pi)$ is determined by $t$.

Q.E.D.

The second part of Proposition 7.2 can be rephrased as the following.

**Corollary 7.3** Every $(K, \pi_K)$-homogeneous Poisson space $(K/K_1, \pi)$, where $K_1$ is a closed subgroup of $K$ containing a maximal torus of $K$, is a Poisson submanifold of $(L_0, \Pi)$ up to a covering given by its Drinfeld map.

**Remark 7.4** Examples of $K_1$ in Proposition 7.3 are $K \cap Q$, where $Q$ is a parabolic subgroup of $G$, so the corresponding homogeneous space is a flag manifold $K/(K \cap Q) \cong G/Q$. 

45
7.3 The normalizer subgroup of $t \in L_0$ in $K$

We now study the normalizer subgroup $N_K(t)$ of an arbitrary $t \in L_0$ in $K$ and determine when it is connected. By Lemma 4.6 and Proposition 5.4, we can write $t = \text{Ad}_k \text{Ad}_a t_{d,\sigma}$ for some $k \in K, a \in A$ and extended signature $\sigma$ for $d = \text{id}$, the trivial diagram automorphism. In what follows, we will write $t_\sigma = t_{\text{id},\sigma}$ and call an extended signature for $d = \text{id}$ simply an extended signature. Write $a = \exp H$ with $H \in a$ and further decompose $H = H_1 + H_2$ with $H_1 \in a \cap m_{\sigma,1}$ and $H_2 \in a \cap \delta_\sigma$. Then $\text{Ad}_{\text{exp} H} t_\sigma = \text{Ad}_{\text{exp} H_1} t_\sigma$ since $H_2$ normalizes $t_\sigma$. Thus, we can assume $t = \text{Ad}_{\text{exp} H} t_\sigma$ with $H \in a \cap m_{\sigma,1}$. We will write $t_{H,\sigma} = \text{Ad}_{\text{exp} H} t_\sigma$.

**Lemma 7.5** For $t_{H,\sigma} = \text{Ad}_{\text{exp} H} t_\sigma$, where $\sigma$ is an extended signature and $H \in a \cap m_{\sigma,1}$, we have $t_{H,\sigma} \cap t = t + n_\sigma + \text{span}_\mathbb{R} \{X_\alpha, Y_\alpha : \sigma(\alpha) = 1, \alpha(H) = 0\}$.

**Proof.** This follows from the fact that

$$\text{Ad}_{\text{exp} H} t_\sigma = t + n_\sigma + \text{span}_\mathbb{R} \{\text{Ad}_{\text{exp} H} X_\alpha, \text{Ad}_{\text{exp} H} Y_\alpha : \sigma(\alpha) = 1\}$$

$$\quad + \text{span}_\mathbb{R} \{i\text{Ad}_{\text{exp} H} X_\alpha, i\text{Ad}_{\text{exp} H} Y_\alpha : \sigma(\alpha) = -1\}.$$  

Q.E.D.

We now describe the normalizer subgroup of $t_{H,\sigma}$ in $K$.

**Notation 7.6** For an extended signature $\sigma$ and $H \in a \cap m_{\sigma,1}$, let $\Sigma_\sigma = \{\alpha \in \Sigma : \sigma(\alpha) = 1\}$. Let $W_\sigma$ be the subgroup of the Weyl group generated by the simple reflections corresponding to the simple roots in the support of $\sigma$. Let $W_{H,\sigma} = \{w \in W_\sigma : w \Sigma_\sigma = \Sigma_\sigma, wH = H\} \subset W_\sigma \subset W$.

Let

$$N'(t_{H,\sigma}) = p^{-1}(W_{H,\sigma}),$$

where $p : N_K(t) \to W = N_K(t)/T$ is the projection from the normalizer subgroup $N_K(t)$ of $t$ in $K$ to the Weyl group. Finally, let $K_{H,\sigma}$ be the connected subgroup of $K$ with Lie algebra $t_{H,\sigma} \cap t$.  

46
**Proposition 7.7** For an extended signature $\sigma$ and $H \in \mathfrak{a} \cap \mathfrak{m}_{\sigma,1}$, the normalizer subgroup $N_K(l_{H,\sigma})$ of $l_{H,\sigma} = \text{Ad}_{\exp H}l_{\sigma}$ is given by

$$N_K(l_{H,\sigma}) = N'(l_{H,\sigma})K_{H,\sigma} = K_{H,\sigma}N'(l_{H,\sigma}).$$

**Proof.** It is clear from Lemma 7.5 that $N'(l_{H,\sigma})$ normalizes $l_{H,\sigma}$, so it normalizes $l_{H,\sigma} \cap \mathfrak{t}$ and the corresponding connected group $K_{H,\sigma}$. This implies the second equality, and the inclusion $K_{H,\sigma}N'(l_{H,\sigma}) \subset N_K(l_{H,\sigma})$.

Conversely, suppose that $k \in K$ normalizes $l_{H,\sigma}$. Then it normalizes the group $K_{H,\sigma}$, so $\text{Ad}_k T$ is a maximal torus of $K_{H,\sigma}$, where $T$ is the maximal torus of $K$ with Lie algebra $\mathfrak{t}$. Thus there exists $k_1 \in K_{H,\sigma}$ such that $\text{Ad}_{k_1} T = T$, i.e., $k_1^{-1} k \in N_K(T) = N_K(\mathfrak{t})$. Write $n = k_1^{-1} k$, so that $k = k_1 n$. It remains to show that $n \in N'(l_{H,\sigma})$.

Denote by $w_n$ the Weyl group element $nT \in W$. Since $n$ normalizes $l_{H,\sigma}$, it normalizes its nilradical $\mathfrak{n}_{H,\sigma}$. Thus $w_n \in W_{\sigma}$. Now for each $\alpha \in [S_{\sigma}]$, the support of $\sigma$, consider the space

$$V_{\alpha} = l_{H,\sigma} \cap (\mathfrak{g}_{\alpha} \oplus \mathfrak{g}_{-\alpha}).$$

By the description of the basis of $\mathfrak{t}_g$, we know that the Killing form of $\mathfrak{g}$ restricted to $V_{\alpha}$ is either negative definite or positive definite depending on whether $\sigma(\alpha) = 1$ or $\sigma(\alpha) = -1$. Now since $n$ normalizes $l_{H,\sigma}$, it permutes the spaces $V_{\alpha}$, for $\alpha \in [S_{\sigma}]$. But $n$ preserves the Killing form, so $\sigma(\alpha) = 1$ implies $\sigma(w_n \alpha) = 1$. In other words, $w_n \Sigma_{\sigma} = \Sigma_{\sigma}$. It also follows that $n$ normalizes $l_{\sigma}$. Therefore we have

$$\text{Ad}_{\exp (w_n H)}l_{\sigma} = \text{Ad}_{\exp H}l_{\sigma}.$$ 

An easy calculation shows that this implies $\alpha(H) = \alpha(w_n H)$ for all $\alpha \in [S_{\sigma}]$. Since $H \in \mathfrak{a} \cap \mathfrak{m}_{\sigma,1}$ and $w_n \in W_{\sigma}$, it follows that $H = w_n H$. Therefore $w_n \in W_{H,\sigma}$, or, equivalently, $n \in N'(l_{H,\sigma})$.

Q.E.D.

**Corollary 7.8** Let the notation be as in Notation 7.6. Then

$$N_K(l_{H,\sigma})/K_{H,\sigma} \cong N'(l_{H,\sigma})/N'(l_{H,\sigma}) \cap K_{H,\sigma}.$$
Remark 7.9 For an extended signature $\sigma$, the group

$$W_{0,\sigma} = \{w \in W : w\Sigma_\sigma = \Sigma_\sigma\}$$

contains the subgroup $R_\sigma$ generated by reflections $\{s_\alpha\}$ for $\alpha \in \Sigma_\sigma$ as a normal subgroup. Indeed, this follows from the formula for $s_\alpha$ and Formula (14) for $\sigma$. Set $Z_\sigma = W_{0,\sigma}/R_\sigma$. Regard $\sigma$ as a signature for the root system $[S_\sigma]$. Then $\sigma$ defines a signature for each irreducible subsystem of $[S_\sigma]$, and we can calculate $Z_\sigma$ separately for each irreducible subsystem. The group $Z_\sigma$ is computed for each simple Lie algebra in [O-S], Table 3, p. 80, and explicit elements are given. For example, when $g = \mathfrak{sl}(n, \mathbb{C})$, then if $l_\sigma \not\sim = \mathfrak{su}(n/2, n/2)$, then $Z_\sigma$ is trivial, and if $l_\sigma \cong \mathfrak{su}(n/2, n/2)$ then $Z_\sigma$ is a group with two elements. $Z_\sigma$ has no more than two elements except in the case when $g = \mathfrak{so}(4n, \mathbb{C})$ and $l_\sigma \cong \mathfrak{so}(2n, 2n)$, when $Z_\sigma$ is the Klein 4-group. In particular, the group $W_{0,\sigma}$ can be calculated explicitly in each case. It follows that we can compute the group $W_{H,\sigma}$ explicitly.

7.4 $(K, \pi_K)$-homogeneous Poisson structures on $K/T$

In this section, we determine all $(K, \pi_K)$-homogeneous Poisson structures on the full flag variety $K/T$, where $T$ is the maximal torus of $K$ with Lie algebra $t$.

By Proposition 7.2, we only need to identify those $t \in L_0$ such that $t \cap t = t$. We can assume $t = t_{H,\sigma} = \text{Ad}_{\exp H} t_{\sigma}$, where $\sigma$ is an extended signature and $H \in a \cap m_{\sigma,1}$, because the Poisson structure on $K/T$ determined by any $t = \text{Ad}_k t_{H,\sigma}$ for some $k \in K$ (such that $t \cap t = t$) will be $K$-equivariantly isomorphic to the one determined by $t_{H,\sigma}$.

**Proposition 7.10** Let $\sigma$ be an extended signature and let $H \in a \cap m_{\sigma,1}$. Let $t_{H,\sigma} = \text{Ad}_{\exp H} t_{\sigma}$. Then $t_{H,\sigma} \cap t = t$ if and only if $\alpha(H) \neq 0$ for all $\alpha \in \Sigma_\sigma$.

**Proof.** This is a direct consequence of Lemma 7.3.

Q.E.D.

For every $t_{H,\sigma}$ such that $t_{H,\sigma} \cap t = t$, denote by $\pi_{H,\sigma}$ the associated $(K, \pi_K)$-homogeneous Poisson structure on $K/T$.

**Corollary 7.11** The collection $\{\pi_{H,\sigma}\}$, as $\sigma$ runs over all extended signatures and as $H$ takes all elements in $a \cap m_{\sigma,1}$ such that $\alpha(H) \neq 0$ when $\sigma(\alpha) = 1$, gives all $(K, \pi_K)$-homogeneous Poisson structure on $K/T$.
An explicit formula for $\pi_{H,\sigma}$ is given in [Lu4] as

$$\pi_{H,\sigma} = p_*\pi_K + \frac{1}{2} \left( \sum_{\alpha \in [S_\sigma] \cap \Sigma_+} \frac{1}{1 - \sigma(\alpha) e^{2\alpha(H)}} X_\alpha \wedge Y_\alpha \right)^0,$$

where $p : K \rightarrow K/T$ is the natural projection, and the second term on the right hand side is the $K$-invariant bi-vector field on $K/T$ whose value at $e = eT$ is the expression given in the parenthesis. The fact that these are all the $(K, \pi_K)$-homogeneous Poisson structures on $K/T$ up to $K$-equivariant isomorphisms is also proved in [Lu4] by a different method. Namely, we show in [Lu4] that every such Poisson structure comes from a solution to the Classical Dynamical Yang-Baxter Equation [E-V]. In [Lu4], we also study some geometrical properties of these Poisson structures such as their symplectic leaves, modular vector fields, and moment maps for the $T$-action.

Recall from Proposition 7.7 and Notation 7.6 that when $t_{H,\sigma} \cap t = t$, the normalizer subgroup $N_K(t_{H,\sigma})$ of $t_{H,\sigma}$ in $K$ lies in the normalizer subgroup of $t$ in $K$, and we have

$$N_K(t_{H,\sigma})/T = W_{H,\sigma} = \{ w \in W_\sigma : w \Sigma_\sigma = \Sigma_\sigma, wH = H \}.$$

When $W_{H,\sigma}$ is trivial, the Poisson manifold $(K/T, \pi_{H,\sigma})$ embeds into $(L_0, \Pi)$ as a Poisson submanifold. When $W_{H,\sigma}$ is not trivial, it follows from Proposition 2.27 that action of $W_{H,\sigma}$ on $K/T$ from the right defined by

$$(K/T) \times W_{H,\sigma} \longrightarrow K/T : (kT, w) \longmapsto kwT$$

is by Poisson isomorphisms. Thus, the group $W_{H,\sigma}$ gives symmetries of the Poisson structure. As we mentioned in Remark 7.9, this group can be calculated case by case.

Remark 7.12 If $H \in a$ is regular in the sense that it is not fixed by any Weyl group element, then $W_{H,\sigma}$ is trivial for any $\sigma$. On the other hand, Borel and de Siebenthal showed that every nontrivial signature $\sigma$ corresponding to the trivial diagram automorphism can be put in a form such that $\sigma(\alpha_k) = -1$ for exactly one simple root $\alpha_k$ [B-deS] or [O-S], Appendix. In particular, the group $W_{0,\sigma}$ contains the Weyl group of a maximal Levi subgroup, so for $W_{H,\sigma}$ to be trivial, $H$ cannot be fixed by any element in a maximal Levi subgroup, so in particular, $H$ can lie in at most one wall.
Example 7.13 We can compute the Poisson structure $\Pi$ on $L_0$ explicitly for the case of $g = \mathfrak{sl}(2, \mathbb{C})$. In this case, it follows from [D-P] that $L_0$ can be $G = \text{PSL}(2, \mathbb{C})$-equivariantly identified with $\mathbb{R}P^3$, regarded as the projectivization of the space $\mathcal{H}$ of $2 \times 2$ Hermitian matrices, where the action of $G$ on $\mathcal{H}$ is by
\[ g \circ X = gX\bar{g}, \quad g \in G, X \in \mathcal{H}. \]
The $R$-matrix $R \in \mathfrak{g} \wedge \mathfrak{g}$ (see Section 2.2) is explicitly given by
\[ R = -\frac{1}{2} (ih \wedge h - X_\alpha \wedge iE_\alpha + Y_\alpha \wedge E_\alpha), \]
where
\[ h = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad X_\alpha = \frac{1}{2} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad Y_\alpha = \frac{1}{2} \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix}, \]
and $E_\alpha = \frac{1}{2} (X_\alpha - iY_\alpha)$. Denote by $\nu : \mathfrak{g} \to \chi^1(\mathcal{H})$ the Lie algebra anti-homomorphism defined by the above action of $G$ on $\mathcal{H}$, where $\chi^1(\mathcal{H})$ is the space of vector fields on $\mathcal{H}$. Then $\Pi = \frac{1}{2} \nu(R)$ is a Poisson structure on $\mathcal{H}$. Write an element of $\mathcal{H}$ as
\[ X = \begin{pmatrix} x & u + iv \\ u - iv & y \end{pmatrix} \]
with $x, y, u, v \in \mathbb{R}$. Then the Poisson brackets for $\Pi$ are given by
\[ \{ x, y \} = 0, \quad \{ x, u \} = -\frac{1}{4} yu, \quad \{ x, v \} = \frac{1}{4} yu \]
\[ \{ y, u \} = \frac{1}{4} yv, \quad \{ y, v \} = -\frac{1}{4} yu, \quad \{ u, v \} = \frac{1}{8} (y - x). \]
Note that
\[ c_1 = x + y \quad \text{and} \quad c_2 = xy - u^2 - v^2 \]
are two Casimir functions. Hence all $\text{SU}(2)$-orbits are Poisson submanifolds. Since this Poisson structure is quadratic, it gives rise to one on $\mathbb{R}P^3$, which is the Poisson structure $\Pi$ on $L_0$. It can be checked that by looking at the $\text{SU}(2)$-orbits through the points in $\mathbb{R}P^3$ corresponding to
\[ \begin{pmatrix} b & 0 \\ 0 & 1 \end{pmatrix}, \quad b \in \mathbb{R}, b \neq 1 \]
we get all the $(K, \pi_K)$-homogeneous Poisson structures $\pi_{H, \sigma}$ on $\text{SU}(2)/S^1$, up to $K$-equivariant isomorphisms, as discussed in Section 7.4. By identifying $\text{SU}(2)/S^1$ with $S^2 = \{(x, y, z) \in \mathbb{R}^3 : x^2 + y^2 + z^2 = 1\}$, these Poisson structures are given by
\[ \{ x, y \} = \frac{1}{4} (x + 2a - 1)z, \quad \{ y, z \} = \frac{1}{4} (x + 2a - 1)x, \quad \{ z, x \} = \frac{1}{4} (x + 2a - 1)y, \]
for $a \in \mathbb{R}$. Note that the antipodal map is a symmetry for the case when $a = \frac{1}{2}$. This corresponds to the fact that the stabilizer subgroup in $SU(2)$ of the point in $\mathbb{RP}^3$ corresponding to \( \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \) has two connected components.
