Edited by Gerald Hart

Changes in glycosphingolipid structures have been shown to occur during the development of several types of human cancers, generating cancer-specific carbohydrate structures that could be used as biomarkers for diagnosis and therapeutic targeting. In this study, we characterized nonacid glycosphingolipids isolated from a human gastric adenocarcinoma by mass spectrometry, enzymatic hydrolysis, and by binding with a battery of carbohydrate-recognizing ligands. We show that the majority of the complex nonacid glycosphingolipids had type 2 (Galβ4GlcNAc) core chains (neolactotetraosylceramide, the Le², H type 2, x₂, and the P1 pentaosylceramides, and the Le³, A type 2, and neolacto hexaosylceramides). We also found glycosphingolipids with type 1 (Galβ3GlcNAc) core (lactotetraosylceramide and the H type 1 pentaosylceramide) and globo (GalαGal core chains (globotriaosylceramide and globotetraosylceramide). Interestingly, we characterized two complex glycosphingolipids as a P1 heptaosylceramide (Galα4Galβ4GlcNAcβ3Galβ4GlcNAcβ3Galβ4GlcNβ1Cer) and a branched P1 decaosylceramide (Galα4Galβ4GlcNAcβ3Galα4Galβ4GlcNAcβ6Galβ4GlcNAcβ3Galβ4Glcβ1Cer). These are novel glycosphingolipid structures and the first reported cases of complex glycosphingolipids larger than pentaosylceramide carrying the P1 trisaccharide. We propose that these P1 glycosphingolipids may represent potential biomarkers for the early diagnosis of gastric cancer.

Gastric adenocarcinoma remains a common cause of cancer death worldwide. In 2020, there were 1.09 million new cases and 769,000 deaths because of stomach cancer (https://www.who.int/news-room/fact-sheets/detail/cancer). Today, almost two-thirds of the stomach cancer cases are found in developing countries. The disease is often diagnosed at a late stage, and the 5-year survival rate is low, in most countries, not more than 15%. It is now well established that chronic Helicobacter pylori colonization of the human stomach is initiated by binding of bacterial adhesins to carbohydrate receptors on the gastric epithelium. A number of different carbohydrate receptor candidates (e.g., gangliotetraosylceramide, the Leb blood group determinant, sulfatide, lactosylceramide, neolacto sequences, lactotetraosylceramide, sialyl-Lea, and related sequences) have been reported (reviewed in Ref. (2)). Despite the multitude of candidate H. pylori glycan receptors, only three carbohydrate-binding adhesins have been characterized to date: the blood group antigen–binding BabA adhesin, the sialic acid–binding SabA adhesin, and the LabA adhesin (reviewed in Ref. (3)).

The first H. pylori adhesin identified was the Leb-binding adhesin BabA (4). H. pylori strains expressing BabA together with VacA and CagA (triple-positive strains) are highly associated with severe gastric diseases, as peptic ulcer or gastric adenocarcinoma. BabA mediates the initial attachment of H. pylori to the human gastric mucosa. The first observation that the fucosylated blood group antigens H type 1 and Leb are recognized by H. pylori BabA was followed by a division of BabA-producing H. pylori strains into specialist and generalist strains, depending on their mode of binding to Leb and related carbohydrate sequences (5). BabA of specialist strains binds only to glycoconjugates with unsubstituted terminal Fucα2Gal sequence as the H type 1 and Leb determinants, whereas the generalist BabA tolerates an addition of αGal or αGalNac to the Gal, as in the blood group A or B type 1 determinants. Thereafter, it was demonstrated that BabA binds to blood group O and A determinants on type 4 core chains (Globo H and Globo A), in addition to blood group determinants on type 1 core chains (6). The structural basis of the different binding modes of BabA was recently determined by X-ray crystallography of the adhesin domain of specialist and generalist BabA, alone and in complex with ABO/Leb oligosaccharides (7).

SabA, the sialic acid–binding adhesin of H. pylori, binds to sialylated glycoconjugates, such as sialyl-Lea and sialyl-Leb (8). The inflammatory response that follows H. pylori colonization of the human gastric mucosa leads to increased expression of sialylated glycans, that is, an increased density of attachment points for the bacteria.

The LabA adhesin was initially reported to bind to LacDiNAc sequences on mucins (9). However, more recent studies have
failed to confirm this interaction (10, 11). Thus, further studies are required to elucidate the carbohydrate-binding specificity of LabA.

We have recently characterized the acid and nonacid glycosphingolipids of the normal human stomach (12, 13). Acid glycosphingolipids recognized by H. pylori SabA were Neu5Acα3-neolactohexaosylceramide and Neu5Acα3-neolactooctaosylceramide (12), and the presence of these two SabA ligands in human gastric adenocarcinoma has previously been reported (14). Among the nonacid glycosphingolipids, there were several ligands for BabA-mediated binding of H. pylori (Leb hexaosylceramide, H type 1 pentaosylceramide, and A type 1/ALeb heptaosylceramide; summarized in Table 1) (13). Other H. pylori-binding glycosphingolipids, recognized by BabA-deficient strains, were lactosylceramide, lacto-ctaosylceramide, the x2 pentaosylceramide, and neo-lactohexaosylceramide (Table 1).

In the present study, nonacid glycosphingolipids isolated from one human gastric adenocarcinoma specimen were characterized by mass spectrometry (MS), enzymatic hydrolysis, and by binding of a battery of carbohydrate-recognizing ligands, with special attention to compounds recognized by H. pylori.

Results

Isolation of human gastric adenocarcinoma glycosphingolipids

Total acid and nonacid glycosphingolipid fractions were isolated from a human gastric adenocarcinoma as described previously (14). Thereby, 430 mg of total neutral glycosphingolipids were obtained from 80 g of starting material. The major part of the nonacid fraction was used for other studies, leaving 30 mg for the structural characterization reported here. Thin-layer chromatography with anisaldehyde staining demonstrated the presence of three major glycosphingolipids in the total nonacid fraction (Fig. 1A, lane 1). These compounds migrated as diosyleramides, triosyleramides, and tetraosyleramides, respectively. A number of low-abundant compounds migrating below the tetrageosylceramide region were also present.

Characterization of the total nonacid glycosphingolipid fraction from human gastric adenocarcinoma

Binding of H. pylori and P-fimbriated Escherichia coli

First, we examined the binding of BabA expressing/Leb binding H. pylori strain J99, lactotetraosylceramide binding H. pylori strain P12, and Galα4Gal binding/P-fimbriated Escherichia coli strain 291-15 to the total nonacid glycosphingolipid fraction from human gastric adenocarcinoma. Here, a distinct binding of the Galα4Gal recognizing E. coli was obtained (Fig. 1B, lane 1). The compounds recognized by the bacteria comigrated with reference globotriaosylceramide and globotetraosylceramide (Fig. 1B, lanes 2 and 3). There was also a weak binding to a compound migrating below globotetraosylceramide (Fig. 1B, lane 1).

Table 1

H. pylori binding nonacid glycosphingolipids in healthy human stomachs

| Trivial name            | Glycosphingolipid structure | BabA binding |
|-------------------------|----------------------------|--------------|
| Lactosylceramide        | Galβ4Glcβ1Cer              | −            |
| Lactotetra              | Galβ3GlcNAcβ3Galβ4Glcβ1Cer | −            |
| Neolactotetra           | Galβ4GlcNAcβ3Galβ4Glcβ1Cer | −            |
| H type 1 penta          | Fuca2Galβ3GlcNAcβ3Galβ4Glcβ1Cer | +           |
| x2 penta                | GalNAcβ3Galβ4GlcNAcβ3Galβ4Glcβ1Cer | −           |
| Leb hexa                | Fuca2Galβ3(Fuca4)GlcNAcβ3Galβ4Glcβ1Cer | +           |
| Neolactohexa            | Galβ4GlcNAcβ3Galβ4GlcNAcβ3Galβ4Glcβ1Cer | −           |
| A type 1/ALeb hepta     | GalNAcβ3(Fuca2)Galβ3(Fuca4)GlcNAcβ3Galβ4Glcβ1Cer | +           |

a Data from Ref. (13).
b Recognized by generalist BabA.
c Binding to lactosylceramide with phytosphingosine and/or hydroxy fatty acids.
d Only the glycan part is shown in the symbolic structures, which are depicted using the Symbol Nomenclature for Glycomics (56, 57).
sloosaccharides obtained from oligosaccharides with isoglobo (Galβ3GlcNAc) core chains. Comparison of retention times and MS² spectra of oligosaccharides from reference glycosphingolipids is also used for identification of oligosaccharides.

The base peak chromatogram from LC–ESI/MS of the oligosaccharides obtained from the total nonacid glycosphingolipid fraction from the human gastric adenocarcinoma had five molecular ions corresponding to oligosaccharides ranging from trisaccharides (detected as [M−H⁺]⁺ ions at m/z 544) to pentasaccharides (detected as [M−H⁺]⁺ ions at m/z 868) (Fig. 2A).

MS² of the molecular ion at m/z 544 gave prominent C-type fragment ions (C₁ at m/z 220 and C₂ at m/z 382) identifying a HexNAc-Hex-Hex sequence (Fig. 2B). There was no ₀₂₄₃ fragment ion at m/z 322, as in the ganglio trisaccharide. Thus, a lacto trisaccharide (GlcNAcβ3Galβ4Glcβ3Glcβ3Glcββ1Cer) was tentatively identified.

The base peak chromatogram had three molecular ions at m/z 706, eluting at 17.9, 24.4, and 24.8 min, respectively. The MS² spectrum of the minor molecular ion at m/z 706 at retention time 17.9 min (Fig. 2C) had a C-type fragment ion series (C₁ at m/z 220, C₂ at m/z 382, and C₃ at m/z 544), demonstrating a HexNAc-Hex-Hex-Hex sequence. The ₀₂₄₃ fragment ion at m/z 484 demonstrated a 4-substituted Hex (15, 16). Taken together, this allowed identification of a globo tetrasaccharide (GalNAcβ3GlcNAcβ3GlcNAcβ3Glcββ4Glcββ1Cer).

MS² of the ion at m/z 706 at the retention time 19.6 min allowed identification of a lacto tetrasaccharide (Galβ4GlcNAcβ3Glu4Glcβ4Glcββ1Cer) (Fig. 2D). This was concluded from the C-type fragment ions (C₂ at m/z 382 and C₃ at m/z 544) identifying a Hex-HexNAc-Hex-Hex sequence, along with the C₂/Z₃ ion (D₁−₂ ion) at m/z 202, obtained by a C₂−Z₃ double cleavage, and diagnostic for a 3-substituted HexNAc, that is a type 1 chain (16).

The molecular ion at m/z 706 at the retention time 24.8 min was the major ion in the base chromatogram. MS² of this ion also gave a series of C-type fragment ions (C₂ at m/z 382 and C₃ at m/z 544) identifying a Hex-HexNAc-Hex-Hex sequence (Fig. 2E). In addition, this spectrum had a ₀₂₄₃ fragment ion at m/z 281 demonstrating a terminal Hex-HexNAc sequence with a 4-substituted HexNAc, that is, a type 2 chain (15, 16). Thus, a neolacto tetrasaccharide (Galβ4GlcNAcβ3Galβ4Glcββ1Cer) was characterized.

Finally, a Hex-HexNAc-Hex-Hex sequence was identified by the series of C-type fragment ions (C₂ at m/z 341, C₃ at m/z 544, and C₄ at m/z 706) obtained by MS² of the ion at m/z 868 eluting at 27.8 to 28.1 min (Fig. 2F). Here, 4-substitution of the internal HexNAc was demonstrated by the ₀₂₄₃ fragment ion at m/z 443 (15, 16). Taken together, this demonstrated neolacto tetrasaccharide substituted with a terminal Hex (Hex-Galβ4GlcNAcβ3Galβ4Glcββ1Cer).

To further characterize the Hex-nLc4 pentasaccharide ion at m/z 868, the oligosaccharide sample was analyzed by liquid chromatography (LC)–ESI/MS once again and subjected to MS³ (Fig. 3). MS³ of the ion at m/z 443 gave a distinct ₀₂₄₃ fragment...
ion at \( m/z \) 281 and a \(^{2,4}A_3\) fragment ion at \( m/z \) 221, demonstrating that the subterminal Hex was substituted at C-4 (15, 16). Thereby, a P1 pentasaccharide (Gal\(\alpha_4\)Gal\(\beta_4\)GlcNAc\(\beta_3\)Gal\(\beta_4\)Glc) was tentatively identified.

In summary, LC–ESI/MS of the oligosaccharides derived from the total nonacid glycosphingolipid fraction from human gastric adenocarcinoma gave identification of a lacto trisaccharide, globo tetrasaccharide, lacto tetrasaccharide, and neolacto tetrasaccharide, and a P1 pentasaccharide.

**Separation of the total nonacid glycosphingolipids from human gastric adenocarcinoma**

To enrich the slow-migrating glycosphingolipids, the total nonacid glycosphingolipid fraction was next separated on an Iatrobeads column (Iatron Labs). Thereby, three glycosphingolipid-containing fractions were obtained. These fractions were denoted fractions GC-1, GC-2, and GC-3, respectively. The glycosphingolipids in fraction GC-1 migrated in the dihexosylceramide region, whereas fraction GC-2 had glycosphingolipids migrating as triaocylceramides and tetraacylcoceramides, and fraction GC-3 contained tetraosylceramides and larger compounds (Fig. 4, lanes 4–6).

**LC–ESI/MS of fractions GC-1 and GC-2**

The native fractions GC-1 and GC-2 were analyzed by LC–ESI/MS using a polyamine column. Thereby, dihexosylceramides with both sphingosine and phytosphingosine, and both hydroxy and nonhydroxy fatty acids with 16 to 24 carbon atoms, were identified in fraction GC-1 (Fig. 4B). Fraction GC-2 had triaocylceramides and tetraacylcoceramides, also with a mixed population of ceramide species with both sphingosine and phytosphingosine, and both hydroxy and nonhydroxy fatty acids with 16 to 24 carbon atoms (Fig. 4C).

**LC–ESI/MS of fraction GC-3**

For characterization of fraction GC-3, an aliquot of this fraction was hydrolyzed with endoglycoceramidase II from Rhodococcus spp. The identification of oligosaccharides was based on their retention times, determined molecular masses, and subsequent MS\(^2\) sequencing. A, base peak chromatogram from LC–ESI/MS of the oligosaccharides obtained from the total nonacid glycosphingolipid fraction from human gastric cancer. B, MS\(^2\) of the ion at \( m/z \) 544 at retention time 20.4 min. C, MS\(^2\) of the ion at \( m/z \) 706 at retention time 17.9 min. D, MS\(^2\) of the ion at \( m/z \) 706 at retention time 24.4 min. E, MS\(^2\) of the ion at \( m/z \) 706 at retention time 24.8 min. F, MS\(^2\) of the ion at \( m/z \) 868 at retention time 27.8 min. The proposed structures in the interpretation formulas are depicted at the right side using the Symbol Nomenclature for Glycomics (SNFG) (56, 57), and nomenclature of fragments was defined by Domon and Costello (58). The oligosaccharides identified in the chromatogram were: Gb4, Gal\(\alpha_4\)Gal\(\beta_4\)GlcNAc\(\beta_3\)Gal\(\beta_4\)Glc; Lc3, GlcNAc\(\beta_3\)Gal\(\beta_4\)Glc; Lc4, Gal\(\beta_3\)GlcNAc\(\beta_3\)Gal\(\beta_4\)Glc; nLc4, Gal\(\beta_4\)GlcNAc\(\beta_3\)Gal\(\beta_4\)Glc; Hex-nLc4; Hex-Gal\(\beta_4\)GlcNAc\(\beta_3\)Gal\(\beta_4\)Glc.

Y-axis, relative intensity. ESI, electrospray ionization; LC, liquid chromatography; MS, mass spectrometry; RT, retention time.
Rhodococcus sp., followed by LC–ESI/MS of the oligosaccharides using a graphitized carbon column. The base peak chromatogram thereby obtained (Fig. S1A) had two predominant molecular ions at \( m/z \) 706 and \( m/z \) 868, and MS² of these gave identification of a neolacto tetrasaccharide and a P1 pentasaccharide, as aforementioned (data not shown). There were also a number of minor molecular ions, which were found by reconstructed ion chromatograms (Fig. S1, B–G). Thus, there were three molecular ions at \( m/z \) 852, eluting at 18.2 min, 21.5 and 24.6 min, and also a number of minor molecular ions at \( m/z \) 909, \( m/z \) 998, \( m/z \) 1055, \( m/z \) 1071, and \( m/z \) 1233. There were also a minor doubly charged molecular ion at \( m/z \) 880 (corresponding to a singly charged ion at \( m/z \) 1760).

A molecular ion at \( m/z \) 852 is consistent with a pentasaccharide with one Fuc, one HexNAc, and three Hex. MS² of the ion at \( m/z \) 852 eluting at 18.2 min gave a spectrum with a dominant ion at \( m/z \) 364 (Fig. 5A). This fragment ion is diagnostic for an internal 4-linked GlcNAc substituted with a Fuc at 3-position and is due to a double glycosidic cleavage of the 3-linked branch (C\(_2\)/Z\(_3\)) (16). There was also a C\(_2\) ion at \( m/z \) 528, and a C\(_3\) ion at \( m/z \) 690, and together these spectral features identified a Le\(^\alpha\) pentasaccharide (Galβ(Fucα3)GlcNAcβ3Galβ4Glc).

The MS² spectrum of the ion at \( m/z \) 852 eluting at 21.5 min was distinctly different (Fig. 5B) and had a series of C-type fragment ions (C\(_2\) at \( m/z \) 325, C\(_3\) at \( m/z \) 528, and C\(_4\) at \( m/z \) 690), identifying a pentasaccharide with Fuc-Hex-HexNAc-Hex-Hex sequence. This demonstrated an H type 1 pentasaccharide (Fucα2Galβ4GlcNAcβ3Galβ4Glc).

The same series of C-type fragment ions (C\(_2\) at \( m/z \) 325, C\(_3\) at \( m/z \) 528, and C\(_4\) at \( m/z \) 690), identifying a pentasaccharide with Fuc-Hex-HexNAc-Hex-Hex sequence, were present in the spectrum obtained by MS² of the ion at \( m/z \) 852 eluting at 24.6 min (Fig. 5C). This spectrum also had a 0.2\(_5\) fragment ion at \( m/z \) 427, which is characteristic for 4-substituted HexNAc, that is, a type 2 carbohydrate chain (15, 16). Thus, an H type 2 pentasaccharide (Fucα2Galβ4GlcNAcβ3Galβ4Glc) was identified.
Figure 4. Characterization of fractions GC-1 and GC-2. A, thin-layer chromatogram detected with anisaldehyde. The glycosphingolipids were separated on glass-backed silica gel plates, using chloroform/methanol/water 60:35:8 (by volume) as solvent system. The lanes were: lane 1, reference lactosylceramide (Galβ4Glcβ1Cer), 4 μg; lane 2, reference globotriaosylceramide (Galβ4Galβ4Glcβ1Cer), 4 μg; lane 3, reference globotetraosylceramide (GalNAcβ3-Galβ4Galβ4Glcβ1Cer), 4 μg; lane 4, fraction GC-1, 4 μg; lane 5, fraction GC-2, 4 μg; lane 6, fraction GC-3, 4 μg. B, molecular ion profile from LC-ESI/MS of fraction GC-1. C, molecular ion profile from LC-ESI/MS of fraction GC-2. Ions from trihexosylceramide are in italics. The peak marked with a * symbol is a nonglycosphingolipid contaminant. In the shorthand nomenclature for fatty acids and bases, the number before the colon refers to the carbon chain length and the number after the colon gives the total number of double bonds in the molecule. Fatty acids with a 2-hydroxy group are denoted by the prefix h before the abbreviation, as, for example, h16:0. S designates sphingosine (d18:1) long-chain base, and P designates phytosphingosine (t18:0) long-chain base. Gb3, Galβ4Galβ4Glcβ1Cer; Lc3, GlcNAcβ3Galβ4Glcβ1Cer; Gb4, GalNAcβ3Galβ4Galβ4Glcβ1Cer; Lc4, Galβ3GlcNAcβ3Galβ4Glcβ1Cer; nLc4, Galβ4GlcNAcβ3Galβ4Glcβ1Cer. Figure 5. LC-ESI/MS of the oligosaccharides derived from fraction GC-3 by hydrolysis with endoglycoceramidase II from Rhodococcus spp. The identification of oligosaccharides was based on their retention times, determined molecular masses, and subsequent MS² sequencing. A, MS² of the ion at m/z 852 at retention time 18.2 min. B, MS² of the ion at m/z 852 at retention time 21.5 min. C, MS² of the ion at m/z 852 at retention time 24.6 min. D, MS² of the ion at m/z 998 at retention time 20.1 min. E, MS² of the ion at m/z 1055 at retention time 18.1 min. F, MS² of the ion at m/z 1071 at retention time 22.9 min. See Fig. S1 for base peak chromatogram. The proposed structures in the interpretation formulas are depicted at the right side using the Symbol Nomenclature for Glycomics (SNFG) (56, 57), and nomenclature of fragments was defined by Domon and Costello (58). ESI, electrospray ionization; LC, liquid chromatography; MS, mass spectrometry; RT, retention time.

MS² of the ion at m/z 998 demonstrated a Le³ hexasaccharide (Fucα2Galβ3(Fucα3)GlcNAcβ3Galβ4Glc) (Fig. 5D). This conclusion was based on the prominent ion at m/z 510, which is obtained by double glycosidic cleavage of the 3-linked branch at C3 and Z3β, and is a signature ion for an internal 4-linked GlcNAc substituted with a Fuc at 3-position (16), together with the C-type fragment ions (C2 at m/z 325 and C4 at m/z 836).

MS² of the molecular ion at m/z 1055 (Fig. 5E) gave a series of C-type fragment ions (C2 at m/z 528, C3 at m/z 731, and C4 at m/z 893) demonstrating a HexNAc-(Fuc-)HexNAc-Hex-Hex sequence. A type 2 core chain was identified by the α2A4 ion at m/z 630. Taken together, this identified a blood group A type 2 hexasaccharide (GalNAcα3(Fucα2)Galβ4GlcNAcβ3Galβ4Glc).

A neolacto hexasaccharide (Galβ4GlcNAcβ3Galβ4GlcNAcβ3Galβ4Glc) was characterized by MS² of the ion at m/z 1071 (Fig. 5F). This was deduced from the C-type fragment ion series (C2 at m/z 382, C3 at m/z 544, C4 at m/z 747, and C5 at m/z 909), demonstrating a Hex-HexNAc-HexNAc-Hex-Hex carbohydrate sequence, along with the α2A4 fragment ion at m/z 646, which demonstrated 4-substitution of the innermost HexNAc.

A molecular ion at m/z 1233 corresponds to a heptasaccharide with two HexNAc and five Hex. The MS² spectrum obtained of m/z 1233 was relatively weak (Fig. 6A) and had a series of the C-type fragment ions (C3 at m/z 544, C4 at m/z 706, C5 at m/z 909, and C6 at m/z 1071) in line with a Hex-HexNAc-Hex-HexNAc-Hex-Hex heptasaccharide. The α2A5 ion at m/z 808 demonstrated 4-substitution of the innermost HexNAc. Taken together, these spectral features gave a tentative identification of a P1 heptasaccharide (Galα3Galβ4GlcNAcβ3Galβ4GlcNAcβ3Galβ4Glc).

A molecular ion at m/z 1760 is consistent with decasaccharide composed of three HexNAc and seven Hex. The spectrum from MS² of the doubly charged molecular ion at m/z 880 (corresponding to a singly charged ion at m/z 1760) (Fig. 6B) was a typical MS² spectrum of a branched oligosaccharide, with predominant C-type ions from the reducing end and relatively weak ions from the nonreducing end (6). The C3α4β ion at m/z 544 indicated Hex-Hex-HexNAc terminals (Fig. 6, B and C), and taken together with the C-type ions at m/z 1233 (C4), m/z 1436 (C5), and m/z 1598 (C6), this indicated a Hex-Hex-HexNAc-(Hex-HexNAc)HexNAc-Hex-Hex sequence. The α2A5 ion at m/z 1135 demonstrated 4-substitution of the innermost HexNAc. Thus, a branched decasaccharide with P1 terminals (Galα4Galβ4GlcNAcβ3Galα4Galβ4GlcNAcβ3Galβ4Glc) was tentatively identified.

The base peak chromatogram also had a minor molecular ion at m/z 909, eluting at 33.6 min (data not shown). Here, the
MS² spectrum was very weak and did not allow a reliable interpretation of the carbohydrate sequence. Therefore, the sample was reduced and reanalyzed by LC–ESI/MS. The spectrum obtained by MS² of the ion at m/z 911 (reduced m/z 909) (Fig. 7) had a number of Y and Z ions (Y2 at m/z 343, Z3 at m/z 528, Y3 at m/z 546, and Y4 at m/z 708), which along with the series of B and C ions (B2 at m/z 364, C2 at m/z 382, B3 at m/z 567, and B4 at m/z 729), identified a HexNAc-Hex-HexNAc-Hex sequence. The 0.2A³ fragment ion at m/z 484 demonstrated that the internal HexNAc was substituted at C-4, that is, a type 2 chain. Taken together, this gave identification of an α2 pentasaccharide (GalNAcβ3Galβ4GlcNAcβ3Galβ4Glc).

α-galactosidase treatment and LC–ESI/MS of fraction GC-3

Three oligosaccharides with terminal Hex-Hex-HexNAc sequence were identified in fraction GC-3 (m/z 868 Hex-Hex-HexNAc-Hex-Hex; m/z 1233 Hex-Hex-HexNAc-Hex-Hex; m/z 880/m/z 1760 Hex-Hex-HexNAc-(Hex-Hex-HexNAc)Hex-HexNAc-Hex-Hex). We speculated that these were the P1 pentasaccharide and a heptasaccharide and decasaccharide with P1 terminals. To substantiate this speculation, the oligosaccharides from the reduced fraction GC-3 were digested with green coffee bean α-galactosidase, which releases nonreducing terminal α(3,4,6)-linked galactose from oligosaccharides. The resulting oligosaccharides were analyzed by LC–ESI/MS (Fig. 8B) and compared with the untreated oligosaccharides (Fig. 8A) from fraction GC-3.

Upon treatment with α-galactosidase, the ions at m/z 870 (reduced m/z 868; Hex-Hex-HexNAc-Hex-Hex pentasaccharide), m/z 1235 (reduced m/z 1233; Hex-Hex-HexNAc-Hex-Hex heptasaccharide), and m/z 881/1762 (reduced m/z 880/1760; Hex-Hex-HexNAc-Hex-HexNAc-Hex-Hex decasaccharide) disappeared (Fig. 8B). Since removal of terminal Galα (162 Da) from m/z 870 and m/z 1235 gives m/z 708 and m/z 1073, respectively, no novel ions appeared in these cases. MS² of the ion at m/z 706 at retention time 20.1 min identified neolacto tetrasaccharide, and MS² of the ion at m/z 1071 at retention time 26.2 min demonstrated a neolacto hexasaccharide (data not shown).

In the α-galactosidase-treated sample, there was also a novel ion at m/z 719/1438 (Fig. 8B), corresponding to removal of two terminal Galα (162 Da x 2) from m/z 881/1762. MS² of the ion at m/z 881/1762 in the untreated sample gave B-type and C-type fragment ions (C3αβ at m/z 544, B4 at m/z 1215, and B6 at m/z 1580) and Y ions (Yαβ at m/z 1235 and Yαβ at m/z 1438) identifying a Hex-Hex-HexNAc-(Hex-Hex-HexNAc)
Hex-HexNAc-Hex-Hex decasaccharide, as aforementioned (Fig. 9A). There was also a \( ^{0.2} \text{A}_{3a/\beta} \) fragment ion at \( m/z \) 443 demonstrating C-4 substitution of the HexNAcs close to the nonreducing ends, that is, type 2 chains.

The MS\(^2 \) spectrum of the novel ion at \( m/z \) 719/1438 (Fig. 9B) had a \( C_{2a/\beta} \) ion at \( m/z \) 382 demonstrating Hex-HexNAc terminals and a series of Y and Z ions (Y\(_3 \) at \( m/z \) 546, Y\(_{4a/\beta} \) at \( m/z \) 1074, Z\(_{5a/\beta} \) at \( m/z \) 1258, and Y\(_{5a/\beta} \) at \( m/z \) 1277). Taken together, this demonstrated a Hex-HexNAc-(Hex-HexNAc)Hex-HexNAc-Hex-Hex octasaccharide.

Thus, the hydrolysis with \( \alpha \)-galactosidase demonstrated that the terminal Hexs of the Hex-Hex-HexNAc-Hex-Hex pentasaccharide, Hex-Hex-HexNAc-Hex-HexNAc-Hex-Hex heptasaccharide, and Hex-Hex-HexNAc-(Hex-Hex-HexNAc) Hex-HexNAc-Hex-Hex decasaccharide were \( \alpha \)-linked.

**Binding of antibodies and lectins to the nonacid subfractions from human gastric adenocarcinoma**

In order to validate the structural information obtained by MS, the binding of a number of carbohydrate-recognizing ligands to fractions GC-1 and GC-3 was thereafter examined in chromatogram binding assays (Fig. 10). The *Solanum tuberosum* lectin binds to lactosylceramide with sphingosine and nonhydroxy fatty acids (17). Thus, the binding of *S. tuberosum* lectin in the dihexosylregion in fraction GC-1 confirmed the presence of lactosylceramide with this ceramide composition (Fig. 10B, lane 2). The Gal\( \beta \)4GlcNAc/Fuc\( \alpha \)2Gal\( \beta \)4GlcNAc recognizing lectin from *Erythrina cristagalli* (18) gave three bands in fraction GC-3 (Fig. 10C, lane 4). The upper sharp band most likely was neolactotetraosylceramide, whereas the lower double band was the H type 2 pentaosylceramide (also shown in Fig. 10F).

The monoclonal antibodies directed against the P1 epitope bound in the pentaosylceramide region in fraction GC-3 (Fig. 10D). The presence of glycosphingolipids with blood group H type 1, H type 2, Le\(^b \), Le\(^s \), and A determinants in fraction GC-3 was confirmed by the binding of monoclonal antibodies (Fig. 10, E–I, lane 4). The antibodies against H type 1, H type 2, Le\(^s \), and Le\(^e \) also recognized slow-migrating compounds in fraction GC-3, indicating the presence of complex glycosphingolipids carrying these determinants.

Binding of *H. pylori* strain J99 and monoclonal antibodies directed against the Le\(^b \) determinant to fractions GC-1 and GC-3 was also tested, but no binding was obtained.

The nonacid glycosphingolipids identified in the human gastric adenocarcinoma are summarized in Table 2.

**Discussion**

There are three identified carbohydrate-binding *H. pylori* adhesins, the Le\(^b \)-binding BabA adhesin, the sialic acid–binding SabA adhesin, and LabA with undefined carbohydrate-binding specificity. In addition, *H. pylori* HopQ protein functions as a carbohydrate-independent adhesin and binds to the N-terminal of human carcinoembryonic antigen–related cell adhesion molecules, which leads to translocation of the CagA pathogenicity island into host cells (19, 20).

In this study, the nonacid glycosphingolipids of a human gastric adenocarcinoma were characterized. The majority of the complex nonacid glycosphingolipids had type 2 (Gal\( \beta \)4GlcNAc) core chains, that is, the neolactotetraosylceramide, the Le\(^e \), H...
type 2, α2, and the P1 pentaosylceramides, and the Leα, A type 2, and neolacto hexaosylceramides. A predominance of glycosphingolipids with type 2 core was also present in the normal human stomachs (13). The gastric adenocarcinoma also had two compounds with type 1 (Galβ3GlcNAc) core; lactotetraosylceramide and the H type 1 pentaosylceramide. In addition, there were compounds with globo (GalαGal) core chains, that is, globotriaosylceramide and globotetraosylceramide. The glycan parts of the dihexosylceramides were not resolved in this study. However, in the healthy human stomach, the dihexosylceramides are a mixture of lactosylceramide and digalactosylceramide (13, 21).

There was no binding of *H. pylori* to the total nonacid glycosphingolipid fraction from the gastric adenocarcinoma, and this fraction had mainly neolactotetraosylceramide and the P1 glycosphingolipid. Minor potential *H. pylori* binding targets identified were lactotetraosylceramide (22), the H type 1 pentaosylceramide (23), the x2 pentaosylceramide, and neolactohexaosylceramide (24). Separation into subfractions was required for characterization of the minor complex fucosylated glycosphingolipids (Lex and H type 2 pentaoxyceramides as well as the Ley and A type 2 hexaosylceramides). This is in contrast to the normal human stomach, where these compounds were characterized using the total nonacid glycosphingolipid fractions (13). Previous immunohistochemistry studies have demonstrated changes in expression of Lewis antigens upon malignant transformation in the stomach, with decreased levels of Leα and increased levels of Leα (25–27). A decrease in blood group ABO antigen expression in gastric cancer has also been reported (28).

Thus, the repertoire of nonacid glycosphingolipids in the gastric adenocarcinoma had both similarities and differences
with the glycosphingolipids previously characterized in the normal human stomach (13), as summarized in Table 3. Several H. pylori-binding compounds (lactotetraosylceramide, neolactotetraosylceramide, the \( \alpha \) and H type 1 pentaosylceramide, and neolactohexaosylceramide) were present in both cases. However, two main targets for BabA-mediated binding of H. pylori, the Le\(^b\) hexaosylceramide and blood group A type 1/ALe\(^b\) heptaosylceramide, were not found in the gastric adenocarcinoma, that is, the adhesion targets for BabA-mediated binding of H. pylori are reduced in gastric cancer. Together, our results support that the BabA-mediated adherence of H. pylori is primarily important for the initial adhesion

Figure 9. \( \alpha \)-galactosidase hydrolysis. The glycosphingolipid-derived oligosaccharides from fraction GC-3, obtained by endoglycoceramidase II hydrolysis, were reduced by treatment with sodium borohydride, and part of the reduced samples was digested with green coffee bean \( \alpha \)-galactosidase. The identification of oligosaccharide was based on their retention times, determined molecular masses, and subsequent \( \text{MS}^2 \) sequencing. A, \( \text{MS}^2 \) of the ion at \( m/z \) 881/1762 at retention time of 30.2 min from LC-ESI/MS of the reduced oligosaccharides obtained by digestion of fraction GC-3 with Rhodococcus endoglycoceramidase II. B, \( \text{MS}^2 \) of the ion at \( m/z \) 718/1436 at retention time 27.7 min from LC-ESI/MS after \( \alpha \)-galactosidase hydrolysis of the reduced oligosaccharides obtained by digestion of fraction GC-3 with Rhodococcus endoglycoceramidase II. The proposed structures in the interpretation formulas are depicted using the Symbol Nomenclature for Glycomics (SNFG) (56, 57), and nomenclature of fragments was defined by Domon and Costello (58). ESI, electrospray ionization; LC, liquid chromatography; MS, mass spectrometry.
of the bacteria to the healthy human stomach, which is crucial for colonization and subsequent infection.

There are several reports of human gastric adenocarcinoma glycosphingolipids from the 1970 to 1980ies (29–33). These studies were focused on incompatible blood group antigens, that is, blood group A and/or and Forssman glycosphingolipids in tumors from blood group O and B individuals. In many cases, polyclonal antibodies were used, and thus to some extent, these findings may be due to crossreactivities with the Tn antigen, since the blood group A antigen, the Forssman determinant, and the Tn antigen all have a terminal α3-linked GalNAc residue (34, 35). However, in some cases, solid chemical evidence demonstrated the presence of blood group A glycosphingolipids in tumors from blood group O individuals (30, 32). The role of such incompatible blood group A antigens in the tumorigenic process is currently not known.

Changes in glycosylation is one hallmark of cancer and are due to abnormally expressed glycosyltransferases and glycosidases in tumor cells, leading to the generation of tumor-associated carbohydrate antigens (36–39). In gastric tumors, the occurrence of truncated O-glycans has been reported (40, 41), and this is associated with cancer aggressiveness and poor prognosis (41, 42). An enhanced expression of sialylated Leα has also been found in gastric cancers (25).

In this study, the identification of glycosphingolipids with the P1 terminal among the gastric adenocarcinoma...
glycosphingolipids was an unexpected finding, since the P1 pentaosylceramide is mainly expressed on human erythrocytes (43), and was not identified in the normal human stomachs (13). The P1 glycosphingolipid has, however, been identified as a marker of ovarian cancer (44).

The characterization of the P1 pentaosylceramide, and the heptaoosylceramide and branched decaosylceramide with P1 terminals, was based on:

(i) Identification of terminal Hex-Hex-HexNac sequences by LC–ESI/MS.
(ii) Binding of monoclonal antibodies directed against the P1 epitope in the pentaosylceramide region.
(iii) A 0.2A2 fragment ion at m/z 281 obtained by MS3, which demonstrated that the subterminal Hex was substituted at C-4 (only seen for the pentaosylceramide).
(iv) Disappearance of the molecular ions corresponding to the pentaosylceramide, heptaoosylceramide, and decaosylceramide upon treatment with α-galactosidase.

Furthermore, terminal α3-linked Gal is not likely since no linear Galα3-terminated glycoconjugates are present in human tissues. This is due to point mutations in the human gene for the a1,3galactosyltransferase, which results in a frameshift and a premature stop codon (45).

The heptaoosylceramide and branched decaosylceramide with P1 terminals are to our knowledge novel glycosphingolipid structures and the first characterization of complex glycosphingolipids larger than pentaosylceramide carrying the P1 trisaccharide.

*H. pylori* binds to several glycosphingolipids with neolacto core chain, as for example, the B5 pentaosylceramide and the x2 pentaosylceramide (24). However, the P1 glycosphingolipid is not recognized by *H. pylori* (24), and thus, the P1 glycosphingolipids in gastric cancer are not novel adhesion targets for the bacteria.

Interestingly, in 1976, Levine (46) reported about a gastric adenocarcinoma in a woman with the rare genotype *pp*, lacking the P1 antigen. Prior to surgery, this patient was given a transfusion with incompatible blood, and thereby, her titers to the bacteria increased from 1:4 to 1:512. The 66-year-old patient survived for 22 years and died from natural causes with no evidence of metastases. Subsequent analysis of the

a Data from the blood group A (Rh+)P human stomach reported in Ref. (14).

b Compounds recognized by *H. pylori* BabA adhesion.

c The compounds have been characterized as *H. pylori* binding in previous studies (reviewed in Ref. (33)).

d Marks the compounds present in the human gastric adenocarcinoma only.
glycosphingolipids in the tumor material demonstrated the presence of a compound, which comigrated with the P1 pentaoxyceramide on thin layer chromatograms, and was degraded by α-galactosidase (47). Thus, our finding of the P1 glycosphingolipids in the gastric adenocarcinoma, along with this classical anecdotal report, suggests that further studies should be done to investigate the potential role of P1 as a diagnostic and prognostic biomarker for gastric cancer, and target for anticancer immunotherapeutics.

**Experimental procedures**

*Glycosphingolipid preparations*

The study was conducted according to the tenets of the Declaration of Helsinki. The gastric adenocarcinoma was collected in the 1970ies at Sahlgrenska University Hospital, Göteborg, Sweden (before the hospital had an ethics committee). The tissue (dry weight 80 g) was obtained at autopsy, and after lyophilization, the tissue was kept at −70 °C for several years. The isolation of total acid and total nonacid glycosphingolipids has been described (14). In brief, the lyophilized tissue was extracted in a Soxhlet apparatus with mixtures of chloroform and methanol (2:1 and 1:9, by volume). The resulting material was pooled and subjected to mild alkaline hydrolysis followed by dialysis. Thereafter, nonpolar compounds were removed by chromatography on a silicic acid column. Acid and nonacid glycosphingolipids were separated by ion change chromatography on a diethylaminoethyl-cellulose column. In order to separate the nonacid glycosphingolipids from alkali-stable phospholipids, the nonacid fractions were then acetylated and separated on a second silicic acid column, followed by deacetylation and dialysis. Final purifications are performed by chromatography on diethylaminoethyl-cellulose and silicic acid columns.

After the first characterization by binding assays and LC–ESI/MS, the nonacid glycosphingolipids were separated on an Iatrobeads column eluted with increasing volumes of methanol in chloroform. The fractions obtained were analyzed by thin layer chromatography and anisaldehyde and thereafter pooled according to their mobility on thin layer chromatograms, resulting in three subfractions, which were denoted fractions GC-1, GC-2, and GC-3.

*Reference glycosphingolipids*

Total acid and nonacid glycosphingolipid fractions were isolated as described (48). Individual glycosphingolipids were isolated by repeated chromatography on silicic acid columns and by HPLC and identified by MS (15, 49) and 1H-NMR spectroscopy (50).

*Thin-layer chromatography*

Thin-layer chromatography was performed on aluminium- or glass-backed silica gel 60 high-performance thin-layer plates (Merck). Glycosphingolipid mixtures (40 μg), or pure glycosphingolipids (4 μg), were applied to the plates and chromatographed using chloroform/methanol/water 60:35:8 (by volume) as solvent system. Chemical detection was done with anisaldehyde (51).

**Chromatogram binding assays**

The carbohydrate-binding ligands and dilutions used in the chromatogram binding assays are given in Table 4. Binding of antibodies to glycosphingolipids separated on thin-layer chromatograms was performed as described by Barone et al. (52). After elution, the dried thin-layer plates were treated with a mixture of 0.5% polyisobutylmethacrylate (w/v) in diethyl ether/n-hexane (5:1, v/v) for 1 min and then air-dried. Thereafter, followed by a 2 h incubation at room temperature with PBS (pH 7.3) containing 2% (w/v) bovine serum albumin, 0.1% (w/v) NaN₃, and 0.1% (w/v) Tween-20 (solution A) to reduce unspecific binding. Then, the chromatograms were incubated for 2 h at room temperature with suspensions of monoclonal antibodies diluted in solution A, followed by washings with PBS.

Two types of secondary antibodies were used for detection. The first type was 125I-labeled (labeled by the iodogen method according to the manufacturer’s [Pierce; catalog no.: 28600] instructions) rabbit antimouse antibodies diluted to 2 × 10⁶ cpm/ml in solution A, which were incubated for 2 h. Thereafter, the plates were washed six times with PBS. Dried chromatograms were then autoradiographed for 12 to 24 h using XAR-5 X-ray films (Carestream; catalog no.: 8941114).

The other type of secondary antibodies used was alkaline phosphate–conjugated goat antimouse antibodies (Sigma–Aldrich; catalog no.: A0162) at a dilution of 1: 500 in solution A, which were incubated for 1 h. Alkaline phosphate–conjugated goat antihuman immunoglobulin M antibodies (Sigma–Aldrich; catalog no.: A3437), at a dilution of 1:400 in solution A, were used for detection of anti-P1 antibodies. The reactions were visualized with 5-bromo-4-chloro-3-indolyl phosphate/nitro blue tetrazolium chromogenic substrate (Sigma–Aldrich; catalog no.: B5655-25TAB).

Binding of 35S-labeled *H. pylori* and P-fimbriated *E. coli* to glycosphingolipids on thin layer chromatograms was done as described (13, 21).

Binding of 125I-labeled *E. cristagalli* lectin (Sigma–Aldrich) to glycosphingolipids on thin layer chromatograms was done as described (18). Chromatogram binding assays with alkaline phosphate–conjugated *S. tuberosum* lectin (bioWORLD) were done as described (17), and 5-bromo-4-chloro-3-indolyl phosphate/nitro blue tetrazolium chromogenic substrate was used for visualization.

**LC–ESI/MS of native glycosphingolipids**

The native glycosphingolipid fractions were analyzed by LC–ESI/MS as described (53). Aliquots of the glycosphingolipid fractions were dissolved in methanol-acetonitrile in proportion 75:25 (by volume) and separated on a 200 × 0.250 mm column, packed in-house with 5 μm poliamine II particles (YMC Europe GmbH). An autosampler, HTC-PAL (CTC Analytics AG), equipped with a cheminert valve (0.25 mm bore) and a 2 μl loop, was used for sample injection.
An Agilent 1100 binary pump (Agilent Technologies) delivered a flow of 250 μl/min, which was split down in an 1/16" microvolume-T (0.15 mm bore) (Vici AG International) by a 50 cm × 50 μm i.d. fused silica capillary before the injector of the autosampler, allowing approximately 2 to 3 μl/min through the column. Samples were eluted with an aqueous gradient (A: 100% acetonitrile to B: 10 mM ammonium bicarbonate). The gradient (0–50% B) was eluted for 40 min, followed by a wash step with 100% B, and equilibration of the column for 20 min. The samples were analyzed in negative ion mode on a linear trap quadrupole (LTQ) ion mass spectrometer (Thermo Electron), with an IonMax standard ESI source equipped with a stainless steel needle kept at −3.5 kV. Compressed air was used as nebulizer gas. The heated capillary was kept at 270 °C, and the capillary voltage was −50 kV. Full scan (m/z 600–1800, two microscans, maximum 100 ms, and target value of 30,000) was performed, followed by data-dependent MS² scans (two microscans, maximum of 100 ms, and target value of 10,000) with normalized collision energy of 35%, isolation window of 2.5 units, activation q = 0.25, and activation time of 30 ms). The threshold for MS² was set to 500 counts.

Data acquisition and processing were conducted with Xcalibur software (Thermo Scientific; version 2.0.7). Manual assignment of glycosphingolipid sequences was done with the assistance of the Glycoworkbench tool (version 2.1) (54), and by comparison of retention times and MS² spectra of reference glycosphingolipids.

### Endoglycoceramidase digestion and LC–ESI/MS

Endoglycoceramidase II from *Rhodococcus* spp. (Takara Bio Europe S.A.) was used for hydrolysis of the nonacid glycosphingolipids. The glycosphingolipids (50 μg) were resuspended in 100 μl 0.05 M sodium acetate buffer, pH 5.0, containing 120 μg sodium cholate, and sonicated briefly. Thereafter, 1 μl of enzyme was added, and the mixture was incubated at 37 °C for 48 h. The reaction was stopped by addition of chloroform/methanol/water to the final proportions 8:4:3 (by volume). The oligosaccharide-containing upper phase thus obtained was separated from detergent on a Sep-Pak QMA cartridge (Waters). The eluant containing the oligosaccharides was dried under nitrogen and under vacuum.

Part of the oligosaccharide samples was reduced by adding 20 μl of 200 mM NaBH₄ in 50 mM KOH to the samples and incubating at 50 °C for 2 h (15). The samples were then acidified by adding 1 μl of glacial acetic acid, and the oligosaccharides were desalted by cation exchange chromatography and thereafter evaporated to dryness.

To characterize anomeric configurations of the terminal Hex-Hex sequence, part of the reduced oligosaccharide samples was digested with α-galactosidase (8 U) from green coffee bean (New England Biolabs), which releases nonreducing terminal α(3,4,6)-linked galactose from oligosaccharides, following the protocol of the manufacturer. Thereafter, the oligosaccharides were desalted using graphitized carbon solid-phase extraction as described (55).

The glycosphingolipid-derived oligosaccharides were resuspended in 50 μl water and analyzed by LC–ESI/MS as described (15). The oligosaccharides were separated on a column (100 × 0.250 mm) packed in-house with 5 μm porous graphite particles (Hypercarb, Thermo-Hypersil). An autosampler, HTC-PAL (CTC Analytics AG) equipped with a cheminert valve (0.25 mm bore) and a 2 μl loop, was used for sample injection. An Agilent 1100 binary pump (Agilent Technologies) delivered a flow of 250 μl/min, which was split down in an 1/16" microvolume-T (0.15 mm bore) (Vici AG International) by a 50 cm × 50 μm i.d. fused silica capillary before the injector of the autosampler, allowing approximately 3 to 5 μl/min through the column. The oligosaccharides (3 μl) were injected on to the column and eluted with an acetonitrile gradient (A: 10 mM ammonium bicarbonate; B: 10 mM ammonium bicarbonate in 80% acetonitrile). The gradient (0–45% B) was eluted for 46 min, followed by a wash step with 100% B, and equilibration of the column for 24 min. A 30 cm × 50 μm i.d. fused silica capillary was used as transfer line to the ion source.

The oligosaccharides were analyzed in negative ion mode on an LTQ ion mass spectrometer. The IonMax standard ESI source on the LTQ mass spectrometer was equipped with a stainless steel needle kept at −3.5 kV. Compressed air was used as nebulizer gas. The heated capillary was kept at 270 °C, and the capillary voltage was −50 kV. Full scan (m/z 380–2000, two microscans, maximum 100 ms, and target value of 30,000) was performed, followed by data-dependent MS² scans of the three most abundant ions in each scan (2 microscans, maximum 100 ms, and target value of 10,000). The threshold for MS² was
set to 500 counts. Normalized collision energy was 35%, and an isolation window of 3 u, an activation q = 0.25, and an activation time of 30 ms, were used. Data acquisition and processing were conducted with Xcalibur software (Thermo Scientific; version 2.0.7).

Manual assignment of glycan sequences was done on the basis of knowledge of mammalian biosynthetic pathways, with the assistance of the Glycoworkbench tool (version 2.1) (54), and by comparison of retention times and MS² spectra of oligosaccharides from reference glycosphingolipids (15).

Data availability

Raw data were uploaded on Glycopost (https://glycopost.glycosmos.org/entry/GPST000232), accessed on December 17, 2021.

Supporting information—This article contains supporting information.

Acknowledgments—We thank the proteomics Core Facility at the Sahlgrenska Academy, University of Gothenburg, where the mass spectrometry analyses were performed.

Author contributions—S. T. conceptualization; C. J. and S. T. methodology; S. T. validation; C. J. and S. T. formal analysis; C. J. investigation; S. T. resources; C. J. data curation; S. T. writing methodology; S. T. validation; C. J. and S. T. formal analysis; C. J.

Funding and additional information—This work was supported by the Swedish Cancer Foundation (grant no.: 20 0759 PjF 01 H; to S. T.).

Conflict of interest—The authors declare that they have no conflicts of interest with the contents of this article.

Abbreviations—The abbreviations used are: BabA, blood group antigen–binding adhesion; CagA, cytotoxin-associated antigen A; LabA, LacdiNac–binding adhesion; LC, liquid chromatography; LTQ, linear trap quadrupole; MS, mass spectrometry; SabA, sialic acid–binding adhesion; VacA, vacuolating cytotoxin A.
