(Dated: August 27, 2014)

In the continuum low-energy model, we calculate the one-loop dynamical polarization functions in ABC-stacked (rhombohedral) \( n \)-layer graphene in a magnetic field. Neglecting the trigonal warping effects, they are derived as functions of wave vector and frequency at finite chemical potential, temperature, band gap, and the width of Landau levels. The analytic results are given in terms of digamma functions and generalized Laguerre polynomials and have the form of double sums over Landau levels. Various particular limits for polarization functions (static, clean, etc.) are discussed. The intralayer and interlayer screened Coulomb potentials are numerically calculated as functions of momentum and frequency.

I. INTRODUCTION

The physical properties of multilayer graphene strongly depend on the stacking order. ABC-stacked or rhombohedral graphene is special because, among many possibilities of stacking order, this material has the flattest electron spectrum at low energy that effectively enhances the role of the electron-electron interactions. According to Refs. 1, 2, rhombohedral graphene together with single and bilayer graphene belongs to a new class of two-dimensional electron systems (2DESs) known as chiral 2DESs 3 due to the chiral properties of its low-energy electron Hamiltonian. If we neglect the trigonal warping effects (for a discussion of these effects and the electron spectrum in multilayer graphene, see Refs. 4, 5), then the electron energy in chiral multilayer graphene with \( n \) layers at low energy is given by \( \varepsilon(p) \sim |p|^\gamma \).

While no gap is observed in single-layer graphene at the neutrality point in the absence of external electromagnetic fields, a gap of 2 meV is reported in bilayer graphene 6, 7. A much larger gap of room-temperature magnitude (\( \sim 42 \)) meV was recently observed in high-mobility ABC-stacked trilayer graphene 8. A sizable gap can be opened in ABC-stacked trilayer graphene subjected to a perpendicular electric field 9, 10, 11 (gap opening and gate-tunable band structure in few-layer graphene are discussed in Refs. 15, 17).

The screening of the Coulomb potential due to many-body interactions is determined by the polarization function, which is also an important physical quantity for the spectrum of collective excitations. The screening is very essential in rhombohedral graphene, unlike single-layer graphene, where it plays a relatively minor role. This is related to the density of states \( D(\varepsilon) \sim \varepsilon^{(2-n)/n} \) at energy \( \varepsilon \) in gapless graphene, which implies that, as \( \varepsilon \rightarrow 0 \), the density of states vanishes for single-layer graphene, is constant for bilayer graphene, and diverges for \( n = 3 \) and higher \( n \)-layer graphene. These considerations are consistent with the static polarization function \( \Pi(k) \) in undoped gapless ABC-stacked multilayer graphene calculated in Ref. 18, according to which \( \Pi(k) \sim k^{2-n} \) and, consequently, the static polarization function diverges for \( n \geq 3 \) as \( k \rightarrow 0 \). The static polarization function in rhombohedral multilayer graphene was studied also in Ref. 19. The screening effects were taken into account within a simplified model in Ref. 20.

The dynamical polarization function in ABC-stacked \( n \)-layer graphene for gapped quasiparticles in the absence of an external magnetic field was recently numerically calculated in Ref. 21 and its fitting function was found. This polarization function was crucial for the analysis of the gap generation. Solving the gap equation, it was found that the gap in rhombohedral graphene attains its maximal value for trilayer graphene and decreases monotonically for \( n \geq 4 \). Thus, although the flattening of the low-energy electron bands suggests that the gap should increase with \( n \), the screening effects, which sharply increase with the number of layers \( n \), turned out to be more essential quantitatively.

In the present paper using the effective low-energy model, we study the dynamical polarization in gapped rhombohedral \( n \)-layer graphene at finite temperature, chemical potential, impurity rate, quasiparticle gap, and magnetic field. In the absence of the trigonal warping effects, we obtain analytical results which, to the best of our knowledge, are not given in the literature. The paper is organized as follows: We set up the model in Sec. II. The dynamical polarization functions in chiral multilayer graphene in a magnetic field are calculated in Sec. III. The static and dynamical screening in clean rhombohedral graphene is studied in Sec. IV. The main results are summarized and discussed in Sec. V. Finally, we provide the details of our calculations in Appendices A, B, and C. The fermion propagator for low-energy quasiparticles in ABC-stacked multilayer graphene in a magnetic field is found in Appendix A. The summation over Matsubara frequencies is performed in Appendix B and some formulas for the polarization

I. INTRODUCTION

The physical properties of multilayer graphene strongly depend on the stacking order. ABC-stacked or rhombohedral graphene is special because, among many possibilities of stacking order, this material has the flattest electron spectrum at low energy that effectively enhances the role of the electron-electron interactions. According to Refs. 1, 2, rhombohedral graphene together with single and bilayer graphene belongs to a new class of two-dimensional electron systems (2DESs) known as chiral 2DESs 3 due to the chiral properties of its low-energy electron Hamiltonian. If we neglect the trigonal warping effects (for a discussion of these effects and the electron spectrum in multilayer graphene, see Refs. 4, 5), then the electron energy in chiral multilayer graphene with \( n \) layers at low energy is given by \( \varepsilon(p) \sim |p|^\gamma \).

While no gap is observed in single-layer graphene at the neutrality point in the absence of external electromagnetic fields, a gap of 2 meV is reported in bilayer graphene 6, 7. A much larger gap of room-temperature magnitude (\( \sim 42 \)) meV was recently observed in high-mobility ABC-stacked trilayer graphene 8. A sizable gap can be opened in ABC-stacked trilayer graphene subjected to a perpendicular electric field 9, 10, 11 (gap opening and gate-tunable band structure in few-layer graphene are discussed in Refs. 15, 17).

The screening of the Coulomb potential due to many-body interactions is determined by the polarization function, which is also an important physical quantity for the spectrum of collective excitations. The screening is very essential in rhombohedral graphene, unlike single-layer graphene, where it plays a relatively minor role. This is related to the density of states \( D(\varepsilon) \sim \varepsilon^{(2-n)/n} \) at energy \( \varepsilon \) in gapless graphene, which implies that, as \( \varepsilon \rightarrow 0 \), the density of states vanishes for single-layer graphene, is constant for bilayer graphene, and diverges for \( n = 3 \) and higher \( n \)-layer graphene. These considerations are consistent with the static polarization function \( \Pi(k) \) in undoped gapless ABC-stacked multilayer graphene calculated in Ref. 18, according to which \( \Pi(k) \sim k^{2-n} \) and, consequently, the static polarization function diverges for \( n \geq 3 \) as \( k \rightarrow 0 \). The static polarization function in rhombohedral multilayer graphene was studied also in Ref. 19. The screening effects were taken into account within a simplified model in Ref. 20.

The dynamical polarization function in ABC-stacked \( n \)-layer graphene for gapped quasiparticles in the absence of an external magnetic field was recently numerically calculated in Ref. 21 and its fitting function was found. This polarization function was crucial for the analysis of the gap generation. Solving the gap equation, it was found that the gap in rhombohedral graphene attains its maximal value for trilayer graphene and decreases monotonically for \( n \geq 4 \). Thus, although the flattening of the low-energy electron bands suggests that the gap should increase with \( n \), the screening effects, which sharply increase with the number of layers \( n \), turned out to be more essential quantitatively.

In the present paper using the effective low-energy model, we study the dynamical polarization in gapped rhombohedral \( n \)-layer graphene at finite temperature, chemical potential, impurity rate, quasiparticle gap, and magnetic field. In the absence of the trigonal warping effects, we obtain analytical results which, to the best of our knowledge, are not given in the literature. The paper is organized as follows: We set up the model in Sec. II. The dynamical polarization functions in chiral multilayer graphene in a magnetic field are calculated in Sec. III. The static and dynamical screening in clean rhombohedral graphene is studied in Sec. IV. The main results are summarized and discussed in Sec. V. Finally, we provide the details of our calculations in Appendices A, B, and C. The fermion propagator for low-energy quasiparticles in ABC-stacked multilayer graphene in a magnetic field is found in Appendix A. The summation over Matsubara frequencies is performed in Appendix B and some formulas for the polarization
functions in the static limit are given in Appendix C.

II. MODEL AND FERMION PROPAGATOR

Neglecting the trigonal warping effects, the low-energy electron Hamiltonian in chiral multilayer graphene with \( n \geq 2 \) layers in a magnetic field is given by

\[
H_0 = \sum_{\tilde{s}} \int d^2 r \Psi_{\tilde{s}}^\dagger(r) \left( \frac{\Delta_{\tilde{s}}}{-a_n \xi^n (-i \hat{D}_x - \hat{D}_y)^n} \right) \Psi_{\tilde{s}}(r),
\]

where \( \hat{D}_i = \partial_i + (ie/c)A_i \) \( (e > 0) \) is the covariant derivative with the vector potential \( \mathbf{A} = (0, Bx, 0) \) which in the Landau gauge describes the magnetic field which points in the \( +z \) direction, \( a_n = \gamma_1(h v_F / \gamma_1)^n \), \( v_F \sim 10^6 m/s \) is the Fermi velocity in graphene, and \( \gamma_1 \approx 0.39 \) eV. Furthermore, \( \Delta_{\tilde{s}} \) is the gap generated dynamically or induced by the electric field applied perpendicular to the planes of graphene. The low-energy effective Hamiltonian \( H_1 \) can be utilized for wave vectors \( k \) up to \( k_W = \gamma_1(h v_F) \). The two-component spinor field \( \Psi_{\tilde{s}} \) carries the valley \( (\xi = \pm \) for the \( K \) and \( K' \) valleys, respectively) and spin \( (s = \pm \) indices. In ABC-stacked multilayer graphene, the low-energy electron states are located only on the outermost layers, which will denote as layers 1 and \( n \) in what follows. Furthermore, we use the standard convention for wave functions: \( \Psi_{\tilde{s}}^T = (\psi_{+A_1}, \psi_{+B_n})_s \), whereas, \( \Psi_{\tilde{s}}^T = (\psi_{-B_n}, \psi_{-A_1})_s \). Here, \( A_1 \) and \( B_n \) correspond to those sublattices in the outermost layers 1 and \( n \), respectively, which are relevant for the low-energy dynamics. Note that, for \( n = 2 \), Hamiltonian \( H_1 \) coincides with the low-energy Hamiltonian of bilayer graphene.

The applicability of the two-component model in multilayer graphene is discussed in Refs. \([1, 24]\). By computing the eigenstates and Landau-level energies in the tight-binding model and comparing them with the prediction of the two-band model, it was shown \([4]\) that the applicability of the two-band model in multilayer graphene is much restricted due to the rather strong trigonal warping effects which are of the order of 10 meV. Since the experimentally observed gap of 42 meV in the absence of external electromagnetic fields in ABC-stacked trilayer graphene is several times larger than the magnitude of the trigonal warping effects, it is natural to expect that the gap will significantly flatten the effects caused by the trigonal warping in trilayer graphene. In our study we neglect the trigonal warping effects that allows us to get analytical expressions for polarization functions. To account for the trigonal warping requires more numerical computations.

By using \( \Psi_{\tilde{s}}(r) = e^{iky} f_{\tilde{s}}(x) \), the effective Hamiltonian for functions \( f_{\tilde{s}}(x) \) takes the form

\[
\tilde{H}_0 = \left( \frac{\Delta_{\tilde{s}}}{-a_n \xi^n (-i \hat{b}^\dagger)^n} \right) \left( -\frac{2^{n/2}a_n \xi^n}{\tilde{\xi}^n} \right) \left( -\frac{2^{n/2}a_n \xi^n}{\tilde{\xi}^n} \right),
\]

where the creation and annihilation operators satisfy the standard commutation relation \( [\hat{b}, \hat{b}^\dagger] = 1 \) and are

\[
\hat{b}^\dagger = -i \frac{l}{\sqrt{2}} \left( \partial_x - k - x/l^2 \right), \quad \hat{b} = -i \frac{l}{\sqrt{2}} \left( \partial_x + k + x/l^2 \right),
\]

with \( l = \sqrt{\hbar c/(eB)} \) being the magnetic length.

We seek the eigenfunctions of Hamiltonian \( \tilde{H}_0 \) in the form of the oscillator wave functions \( u_N \):

\[
f(N, k, x) = \left( \frac{c_1 u_{N-n}(\eta)}{c_2 u_N(\eta)} \right), \quad u_N(\eta) = \frac{e^{-\eta^2/2} H_N(\eta)}{\sqrt{2^{N+1} N! \pi^{1/4} 2^l}},
\]

where \( \eta = kl + \frac{x}{l}, N \geq n, |c_1|^2 + |c_2|^2 = 1, \) and \( H_N(\eta) \) are the Hermite polynomials. The creation and annihilation operators \( \hat{b}^\dagger \) and \( \hat{b} \) are the Landau-level ladder operators and they act on the functions \( u_N(\eta) \) in the standard way. By using Eqs. \([2, 4]\), we find energy levels at fixed valley and spin:

\[
E_{N\alpha} = \alpha M_N, \quad M_N = \sqrt{\Delta_{\tilde{s}}^2 + \mathcal{E}_n^2 N(N - 1) \ldots (N - n + 1), \quad N \geq n, \quad \alpha = \pm 1,
\]

where \( \mathcal{E}_n = \gamma_1 \left[ 2 h^2 v_F^2 / (\gamma_1^2 l^2) \right]^{n/2} \) is the Landau scale in \( n \)-layer graphene and eigenfunctions for higher Landau levels (LLs) are given by

\[
\Psi_{\tilde{s}}(N, k, \alpha; x, y) = e^{iky} \frac{1}{\sqrt{2M_N}} \left( \frac{\sqrt{M_N + \alpha \Delta_{\tilde{s}} u_{N-n}(\eta)}}{(-i)^n \alpha \xi^n \sqrt{M_N - \alpha \Delta_{\tilde{s}} u_N(\eta)}} \right), \quad N \geq n.
\]
For the lowest Landau level (LLL) $N = 0, \ldots, n-1$, we have $E = -\Delta z$ and the corresponding eigenfunctions are

$$
\Psi_{LLL}(N, k, \alpha = -1; x, y) = e^{iky} \begin{pmatrix} 0 \\ u_N(\eta) \end{pmatrix}, \quad N = 0, \ldots, n-1.
$$

(7)

The fermion Green’s function satisfies the equation,

$$(\omega - H_0)S(r, r'; \omega) = \delta(r - r'),
$$

(8)

and can be found through the expansion over the eigenfunctions (see, Appendix A). It has the form

$$
S(r, r'; \omega) = \exp(i\Phi(r, r')) \tilde{S}(r - r'; \omega),
$$

(9)

where $\Phi(r, r') = \frac{i e}{\hbar c} \int r' r A_{z}^{ext}(z) dz$ is the Schwinger phase and $\tilde{S}(r - r'; \omega)$ is the translation-invariant part which is given by Eq. (A5).

The electron-electron Coulomb interaction is described by the following interaction Hamiltonian:

$$
H_{int} = \frac{\epsilon^2}{2\kappa} \int d^3r d^3r' \frac{n_{el}(r)n_{el}(r')}{|r - r'|},
$$

(10)

where $\kappa$ is the dielectric constant, $n_{el}(r) = \delta(z - (n-1)d/2)\rho_1(x) + \delta(z + (n-1)d/2)\rho_n(x)$ is the three-dimensional electron density in the outermost layers of ABC-stacked $n$-layer graphene ($d \approx 0.35 \text{nm}$ is the distance between the two neighbor layers), and two-dimensional charge densities $\rho_1(x)$ and $\rho_n(x)$ in the outermost layers 1 and $n$ are

$$
\rho_1(x) = \sum_{\xi_s} \Psi^\dagger_{\xi_s}(x) P_1 \Psi_{\xi_s}(x), \quad \rho_n(x) = \sum_{\xi_s} \Psi^\dagger_{\xi_s}(x) P_n \Psi_{\xi_s}(x),
$$

(11)

where $P_1 = (1 + \xi r^3)/2$ and $P_n = (1 - \xi r^3)/2$ are projectors on states in the layers 1 and $n$, respectively. (The appearance of $\xi$ in the projectors is related to our choice of the form of the spinor $\Psi_{\xi_s}$.)

Integrating over $z$ and $z'$ in Eq. (10), one can rewrite the interaction Hamiltonian as follows:

$$
H_{int} = \frac{1}{2} \int d^2x d^2x' \left[ V(x - x') \left( \rho_1(x)\rho_1(x') + \rho_n(x)\rho_n(x') \right) + 2V_{1n}(x - x')\rho_1(x)\rho_n(x') \right].
$$

(12)

Here, the potential $V(x)$ describes the intralayer interactions and, therefore, coincides with the bare potential in single-layer graphene whose Fourier transform is given by $V(k) = 2\pi e^2/(\kappa k)$. The potential $V_{1n}$ describes the interlayer electron interactions and its Fourier transform is $V_{1n}(k) = (2\pi e^2/\kappa)(e^{-k(n-1)d}/k)$. Note that the form of the interaction Hamiltonian (12) coincides with that in bilayer graphene [21].

### III. DYNAMICAL POLARIZATION FUNCTIONS AND EFFECTIVE INTERACTIONS

The dynamical polarization determines such physically interesting properties as the effective electron-electron interaction, the Friedel oscillations, and the spectrum of collective modes. In multilayer graphene the dynamical polarization functions $\Pi_{jk}$ describe the electron-density correlations on the layers $j, k = 1, n$,

$$
\delta(\omega + \omega')\delta(k + k')\Pi_{jk}(\omega, k) = -i\langle 0|\rho_j(\omega, k)\rho_k(\omega', k')|0\rangle.
$$

(13)

Since the electron states in the low-energy model are located on the outermost layers of ABC-stacked multilayer graphene, there are only two independent functions, $\Pi_{11} = \Pi_{nn}$ and $\Pi_{1n} = \Pi_{n1}$, which describe the correlations of the electron densities on the same and two different layers. The equalities $\Pi_{11} = \Pi_{nn}, \Pi_{1n} = \Pi_{n1}$ are almost evident from physical equivalence of the outermost layers but can be proved mathematically [see the text after Eq. (21) below].

Taking into account the screening effects, the bare intralayer $V(k)$ and interlayer $V_{1n}(k)$ electron-electron interactions transform into

$$
\hat{V}_{\text{eff}} = \hat{V} \cdot \frac{1}{1 + \hat{V} \cdot \Pi} = \begin{pmatrix} V_{\text{eff}} & V_{1n \text{eff}} \\ V_{1n \text{eff}} & V_{\text{eff}} \end{pmatrix}, \quad \hat{V} = \begin{pmatrix} V & V_{1n} \\ V_{1n} & V \end{pmatrix}, \quad \hat{\Pi} = \begin{pmatrix} \Pi_{11} & \Pi_{1n} \\ \Pi_{1n} & \Pi_{n1} \end{pmatrix},
$$

(14)
with
\[ V_{\text{eff}}(\omega, k) = \frac{2\pi e^2}{\kappa} \frac{k + \frac{4\pi e^2}{\kappa} \Pi_{11}(1 - e^{-2(n-1)kd})}{[k + \frac{4\pi e^2}{\kappa} \Pi_{11}(1 + e^{-2(n-1)kd})] [k + \frac{4\pi e^2}{\kappa} (\Pi_{11} - \Pi_{1n})(1 - e^{-(n-1)kd})]}, \tag{15} \]
\[ V_{1n,\text{eff}}(\omega, k) = \frac{2\pi e^2}{\kappa} \frac{k^{e^2}e^{-\frac{1}{4}\Pi_{11}(n-1)d}}{[k + \frac{4\pi e^2}{\kappa} (\Pi_{11} + \Pi_{1n})(1 + e^{-\frac{1}{2}(n-1)kd})] [k + \frac{4\pi e^2}{\kappa} (\Pi_{11} - \Pi_{1n})(1 - e^{-(n-1)kd})]} \tag{16} \]

Since \( \Pi_{11} \) and \( \Pi_{1n} \) depend on \( \omega \), the effective interactions \( V_{\text{eff}} \) and \( V_{1n,\text{eff}} \) depend on it, too. Note that the form of the effective interactions \( V_{\text{eff}} \) and \( V_{1n,\text{eff}} \) in rhombohedral graphene in the low-energy model is the same as in bilayer graphene (see, e.g., Appendix A in Ref. 25).

Our low-energy model is valid up to the ultraviolet cutoff \( k_W = \gamma_1/(\hbar v_F) \). Since \( k_W d = 0.2 \), we can expand for \( n \leq 3 \) the exponentials in Eqs. 15 and 16 in the Taylor series in \( k \) for all \( k \) up to the cutoff. Then, retaining only the zero and first terms in these expansions, we obtain the following effective interactions which are expected to be good approximations in the infrared (IR) region for all \( n \) rather than only for \( n \leq 3 \):
\[ V_{\text{eff}}^R(\omega, k) = \frac{2\pi e^2}{\kappa} \frac{1 + \frac{4\pi e^2}{\kappa} \Pi_{11}(n-1)d}{[k + \frac{4\pi e^2}{\kappa} \Pi_{11}(1 + \frac{4\pi e^2}{\kappa} (\Pi_{11} - \Pi_{1n})(n-1)d)]}, \tag{17} \]
\[ V_{1n,\text{eff}}^R(\omega, k) = \frac{2\pi e^2}{\kappa} \frac{1 - \frac{4\pi e^2}{\kappa} \Pi_{1n}(n-1)d}{[k + \frac{4\pi e^2}{\kappa} \Pi_{1n}(1 + \frac{4\pi e^2}{\kappa} (\Pi_{11} - \Pi_{1n})(n-1)d)]}, \tag{18} \]

where
\[ \Pi(\omega, k) = \Pi_{11}(\omega, k) + \Pi_{1n}(\omega, k). \tag{19} \]

It was noted in Ref. 21 when studying the gap generation in chiral multilayer graphene in the absence of a magnetic field that the polarization functions in the numerator and in the second square brackets in the denominator of the effective interactions 15 and 16 somewhat compensate each other. Therefore, we may try to further simplify the effective interactions 17 and 18 by approximating them by
\[ V_{\text{app}}(\omega, k) = V_{1n,\text{app}}(\omega, k) = \frac{2\pi e^2}{\kappa} \frac{1}{[k + \frac{4\pi e^2}{\kappa} \Pi_{1n}(n-1)d]} \tag{20} \]

The approximate expressions 17, 18, and 20 will be discussed and compared with the effective interactions 15 and 16 in the next section after we calculate the polarization functions.

The dynamical polarization functions are given by
\[ \Pi_{jk}(\omega, r) = i \int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} \text{Tr} \left[ P_j \bar{S}(r, \omega')P_k \bar{S}(-r, \omega' - \omega) \right], \tag{21} \]

where the trace is taken over spinor, valley, and spin indices. The scalar functions \( \Pi_{jk}(\omega, r) \) depend on \( r^2 \). Since the trace \( \text{Tr} \) in explicit expressions for \( \Pi_{jk} \) includes the summation over the valley index \( \xi = \pm \), one can make the change \( \xi \to -\xi \), then the projector \( P_1 \) changes to \( P_n \) [see definitions of the projectors \( P_1, P_n \) after Eq. 11]. Furthermore, the definition of the propagator Eq. (A5) implies in the case of valley independent gaps that \( \bar{S}(\omega, r, -\xi) = \bar{S}(\omega, -r, \xi) \), hence we obtain the symmetry properties \( \Pi_{11}(\omega, r) = \Pi_{nn}(\omega, r), \Pi_{1n}(\omega, r) = \Pi_{n1}(\omega, r) \). This symmetry breaks for gaps depending on the valley index \( \xi \) (like \( \Delta_\xi \equiv \Delta \) but not \( \Delta_\xi \approx \xi \Delta \)), and for simplicity, in what follows we consider (if not stated otherwise) a gap which does not depend on valley and spin indices, \( \Delta_\xi \equiv \Delta \). This is the so-called Haldane gap 20 and the corresponding generalization to valley and spin-dependent gaps is straightforward.

Taking into account Eq. (A5), we obtain \( (z = r^2/2\ell^2) \)
\[ \Pi_{11}(\omega, r) = \frac{2ie^{-z}}{(2\pi\ell^2)^2} \int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} \sum_{N, N' = 0} \left( \omega' - \Delta \right)(\omega' - \omega - \Delta)L_N(z)L_{N'}(z) + (\omega' + \Delta)(\omega' - \omega + \Delta)L_N(z) L_{N'-n}(z) \right) \]
\[ \left( \omega'^2 - M_\xi^2 \right) \left( \omega'^2 - M_\xi^2 \right) \tag{22} \]
\[ \Pi_{1n}(\omega, r) = \frac{2ie^{-z}}{(2\pi\ell^2)^2} \int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} \sum_{N, N' = 0} \left( \frac{2\sigma_n}{n} \right) L_N(z) L_{N'-n}(z) \]
where the functions \( L_N^p(x) \) are generalized Laguerre polynomials; by definition, \( L_N(x) = L_N^0(x) \), \( L_N^{n}(-x) = 0 \) and \( M_N = |\Delta| \) if \( N < n \). Using Eq. (11) in Appendix B we perform the Fourier transform and find the following dynamical polarization functions in momentum space:

\[
\Pi_{11}(\omega, k) = \frac{i}{\pi l^2} \int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} \sum_{N,N'=0}^{\infty} \frac{(-1)^{N+N'} e^{-\gamma}}{(\omega'^2 - M_N^2)((\omega' - \omega)^2 - M_{N'}^2)} \times \left[ (\omega' - \Delta)(\omega' - \omega - \Delta)L_N^{N-N'}(y)L_N^{N'-N}(y) + (\omega' + \Delta)(\omega' - \omega + \Delta)L_N^{N-N'}(y)L_N^{N'-N}(y) \right],
\]

\[
\Pi_{1n}(\omega, k) = \frac{i}{\pi l^2} \int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} \sum_{N,N'=0}^{\infty} \frac{(-1)^{N+N'} e^{-\gamma}}{(\omega'^2 - M_N^2)((\omega' - \omega)^2 - M_{N'}^2)} \times 2 \left[ \frac{\omega^2}{2} N(N-1) \ldots (N-n+1) \right] L_N^{N-N'}(y)L_N^{N'-N}(y).
\]

At finite temperature and chemical potential the integration over \( \omega' \) is replaced by the sum over Matsubara frequencies \( \int d\omega' \rightarrow 2\pi i T \sum_{m=-\infty}^{+\infty} \), \( \omega' \rightarrow i\omega_m + \mu \), where \( \omega_m = \pi T(2m+1) \) and \( \omega \rightarrow i\Omega_p \), \( \Omega_p = 2\pi T \). In order to take into account the finite width \( \Gamma_N \) of the Landau levels or, equivalently, the scattering rate of quasiparticles, we replace also \( i\omega_m \rightarrow i\omega_m + i\Gamma_N \text{sgn} \omega_m \). The width \( \Gamma_N \) is expressed through the retarded fermion self energy and, in general, depends on energy, temperature, magnetic field, and the Landau-level index. In our calculations, we assume that the width is independent of energy (frequency) but we keep its dependence on the Landau-level index. The summation over the Matsubara frequencies in the polarization functions is performed in Appendix B. Our final analytical expressions for the dynamical polarization functions after analytical continuation take the form of double sums over Landau levels:

\[
\Pi_{11}(\omega, y) = -\frac{e^{-y}}{4\pi l^2} \sum_{N,N'=0}^{\infty} \frac{(-1)^{N+N'} S(N, N', \lambda, \lambda', \omega)}{M_N M_{N'}} \sum_{\lambda, \lambda' = \pm 1} S(N, N', \lambda, \lambda', \omega)
\]

\[
\times \left[ (M_N - \lambda\Delta)(M_{N'} + \lambda'\Delta)L_N^{N-N'}(y)L_{N'}^{N'-N}(y) + (M_N + \lambda\Delta)(M_{N'} + \lambda'\Delta)L_N^{N-N'}(y)L_{N'}^{N'-N}(y) \right],
\]

\[
\Pi_{1n}(\omega, y) = -\frac{e^{-y}}{2\pi l^2} \sum_{N,N'=0}^{\infty} \frac{(-1)^{N+N'} N!}{M_N M_{N'}} \sum_{\lambda, \lambda' = \pm 1} \lambda' \alpha S(N, N', \lambda, \lambda', \omega),
\]

where the function \( S(N, N', \lambda, \lambda', \omega) \) is defined in Eq. (11) and is given in terms of digamma functions. The polarization functions \( \Pi_{11} \) and \( \Pi_{1n} \) are analytical functions of \( \omega \) in the whole upper complex half plane. The sums over the Landau levels in the two independent polarization functions are convergent for \( n \geq 3 \); however, they require an ultraviolet cutoff in the case \( n = 1, 2 \) which is provided by the band width.

The obtained expressions for polarization functions in the form of double sums over Landau levels are most convenient to use at large magnetic fields when one can take into account the contribution of the fewest Landau levels. To study the limit of weak magnetic field it is better to return to Eqs. (12) and (13) where the dependence on \( N, N' \) is factorized. The weak-magnetic-field limit \( (l \rightarrow \infty) \) can be obtained by replacing \( N \rightarrow k^2 l^2/2 \) with the sum turning into the integral over \( k^2 \) and using the asymptotic formula for the Laguerre polynomials,

\[
L_N \left( \frac{x}{N} \right) = J_0(2\sqrt{x}), \quad N \rightarrow \infty
\]

[see, Eq. (10.12.36) in Ref. (27)].

IV. STATIC AND DYNAMICAL SCREENING IN CLEAN RHOMBOHEDRAL GRAPHENE

A. Static screening

The static polarization functions are derived in Appendix C are given by Eqs. (13) and (14) in the general case and by Eq. (17) and (18) in the clean case. In order to illustrate formulas (17) and (18) at arbitrary momenta,
and $\hbar$ 

FIG. 2: (Color online) The dimensionless effective static in trilayer, $\tilde{\Pi}(0,y)$ (blue dashed line), $\tilde{\Pi}_{13}(0,y)$ (black dash-dotted line), and $\tilde{\Pi}(0,y)$ (red solid line). (b) The function $\Pi(0,y)$ for different numbers of layers: $n = 1$ (green dash-double-dotted line), $n = 2$ (dash-dotted black line), $n = 3$ (blue dashed line), and $n = 5$ (red solid line).

We plot in Fig. 1(a) the dimensionless polarization functions $\tilde{\Pi}_{11}(0,y) = \frac{2\hbar^2 e^2}{\gamma_1} \Pi_{11}(0,y)$, and also their sum $\tilde{\Pi}(0,y) = \tilde{\Pi}_{11}(0,y) + \tilde{\Pi}_{13}(0,y)$ in gapless clean ABC-stacked trilayer graphene ($2\hbar^2 v_F^2/\gamma_1$ is a convenient dimensional factor which can be expressed through the Landau scale in bilayer graphene as follows: $2\hbar^2 v_F^2/\gamma_1 = E_2(\ell^2)$. Clearly, at large $y$ (or $\ell \to \infty$), both functions tend to their zero-magnetic-field values. The function $\tilde{\Pi}_{11}(0,y)$ monotonically decreases with $y$ while $\tilde{\Pi}_{13}(0,y)$ monotonically increases practically for all values of $y$ in the considered interval and chosen values of temperature, chemical potential, and magnetic field. Since $\tilde{\Pi}_{11}(0,y)$ decreases more steeply than $\tilde{\Pi}_{13}(0,y)$ increases, this leads to the appearance of a maximum in the sum of these functions $\tilde{\Pi}(0,y)$ at some intermediate value of $y$. In general, the behavior of these functions at intermediate values of $y$ can qualitatively change depending on the values of parameters $\ell T$ and $\ell\mu$. Also, in panel (b) of Fig. 1 we present the function $\tilde{\Pi}(0,y)$ for different numbers of layers. As seen, the polarization functions, and consequently the screening effects, increase with the number of layers $n$.

We plot in Fig. 2 the dimensionless [multiplied by the factor $\kappa\gamma_1/(2\pi e^2\hbar v_F)$] effective interactions given by Eqs. (15) and (16) and approximate expressions (17), (18), and (20) in the ABC-stacked trilayer graphene for $\omega = 0$ and $\kappa = 5$: $V_{eff}(0,k) = V_{eff}(0,k)\kappa\gamma_1/(2\pi e^2\hbar v_F)$, $\tilde{V}_{13\ eff}(0,k) = V_{13\ eff}(0,k)\kappa\gamma_1/(2\pi e^2\hbar v_F)$. As expected, $V_{eff}^{LR}$ and $V_{1n eff}^{LR}$ given by Eqs. (17) and (18) and plotted as blue dashed lines in Fig. 2 excellently match for small momenta the effective interactions (15) and (16) plotted as red solid lines. [Note that the appearance of a minimum in the screened Coulomb interactions is connected with the presence of a maximum in the polarization function $\tilde{\Pi}(0,y)$]. However, the corresponding curves deviate significantly for large momenta (especially so for $V_{eff}^{LR}$ and $V_{eff}$). The approximate effective interactions, given by Eq. (20) and plotted as black dash-dotted lines in Fig. 2 reproduce well the behavior of the effective interactions (15) and (16) for all $k$. The two curves are only shifted with respect to one another. We checked that this is true for $n \leq 8$; still the agreement worsens (especially so at large $k$) as $n$ grows. Moreover, the discrepancies between the corresponding dependencies can be practically completely eliminated by adjusting the dielectric constants in $V_{eff}^{appr}$ and $V_{1n eff}^{appr}$. Since the approximate effective interactions (20) depend
only on $\Pi = \Pi_{11} + \Pi_{1n}$, further in this section we will analyze the polarization function $\Pi$.

![Image of polarization function graphs](image)

**FIG. 3:** (Color online) The dimensionless static polarization function $\tilde{\Pi}(0,k)$ in gapped and gapless trilayer graphene, for $T = \mu = 0$, and different values of the magnetic field: red solid lines are for $B = 0$, blue dashed lines are for $B = 1$ T, black dash-dotted lines are for $B = 5$ T, green dash-double-dotted lines are for $B = 10$ T. (a) $\Delta = 0.01\gamma_1$, (b) $\Delta = 0$.

In order to see how the magnetic field affects the screening, we plot in Fig. 3 the static dimensionless polarization function $\tilde{\Pi}(0,k)$ as a function of the wave vector $k = |k|$ for different values of magnetic field in gapped and gapless trilayer graphene. Clearly, the magnetic field suppresses the screening. According to Fig. 3(a), the larger is the magnetic field, the stronger is the suppression (compare blue, green, and black lines). The role of magnetic field is especially dramatic in gapless graphene. The magnetic field qualitatively changes the behavior of the polarization functions at small wavevectors $|k| \leq l^{-1}$. Indeed, while the static polarization function $\Pi(0,k)$ diverges as $k \to 0$ for $n \geq 3$ in the gapless case without magnetic field [see, red line in the panel Fig. 3(b)] , it is no longer divergent in the presence of a magnetic field (see, blue, green, and black lines).

The asymptotical behavior of the screened Coulomb potential at small and large distances is determined by the asymptotics of the polarization function $\Pi(0,k) = \Pi_{11}(0,k) + \Pi_{1n}(0,k)$ at large and small wave vectors, respectively. At small wave vector values ($k \to 0$), the behavior of $\Pi(0,k)$ can be found from Eqs. (C3) and (C4) by taking into account the values of Laguerre polynomials at zero: $L_0^m(0) = (m+n)!/(m!)^2$, $(L_0^m)'(0) = - (m+n)!/[m! (n-1)!]$. By using $\mathcal{L}^2/N!/(N-n)! = M^2_N - \Delta^2$, we get

$$
\Pi(0,k) \simeq a + bk^2,
$$

where the coefficients $a$ and $b$ are expressed in terms of the digamma function and its derivative

$$
a = \Pi(0,0) = \frac{1}{2\pi^2 T} \sum_{N=0}^{\infty} \sum_{\lambda = \pm 1} ' \Re \psi' \left( \frac{1}{2} + \frac{\Gamma_N}{2\pi T} + \frac{\mu - \lambda M_N}{2\pi i T} \right),
$$

$$
b = - \frac{1}{4\pi^2 T} \sum_{N=0}^{\infty} \sum_{\lambda, \lambda' = \pm 1} ' \left[ 2N + 1 - n \left( 1 + \frac{\Delta}{M_N} \right) \right] \Re \psi' \left( \frac{1}{2} + \frac{\Gamma_N}{2\pi T} + \frac{\mu - \lambda M_N}{2\pi i T} \right)
$$

$$
+ \frac{1}{4\pi^2} \sum_{N=0}^{\infty} \sum_{\lambda, \lambda' = \pm 1} '' \Im \left\{ \psi \left( \frac{1}{2} \pm \frac{\Gamma_N}{2\pi T} + \frac{\mu - \lambda M_N}{2\pi i T} \right) - \psi \left( \frac{1}{2} \pm \frac{\Gamma_{N+1}}{2\pi T} + \frac{\mu - \lambda' M_{N+1}}{2\pi i T} \right) \right\}
$$

$$
\times \left[ 2(N+1) \left( 1 + \lambda \lambda' \frac{M_N}{M_{N+1}} \right) - n \left( 1 + \frac{\Delta}{M_N} \right) \left( 1 + \lambda' \frac{\Delta}{M_{N+1}} \right) \right].
$$

Here the notation $'$ means that only the term with $\lambda = -1$ is retained in the sum if $N < n$, and $''$ means that only the terms with $\lambda = -1$ (if $N < n$) and $\lambda' = -1$ (if $N < n - 1$) are retained. One can see that the parameter $a$ receives the contribution only from intra-Landau-level ($N \leftrightarrow N$) transitions while the parameter $b$ contains also the contributions from the transitions between adjacent Landau levels $N \leftrightarrow N \pm 1$.

The polarization function at zero frequency and momentum $[29]$ obeys the following relation [28]:

$$
\Pi(0,0) = \int \frac{d\epsilon D(\epsilon)}{4T \cosh^2 \left( \frac{\epsilon - \mu}{2T} \right)},
$$
where $D(\epsilon)$ is the density of states (DOS) in multilayer graphene with impurities in a magnetic field,

$$D(\epsilon) = \frac{1}{\pi l^2} \sum_{N=0}^{\infty} \sum_{\lambda=\pm1}^{\prime} \frac{\Gamma_N}{(\epsilon - \lambda M_N)^2 + \Gamma_N^2}. \quad (32)$$

Obviously, $\Pi(0, 0)$ is an oscillating function of chemical potential and magnetic field. At zero temperature and finite scattering rate it is simply equal to the DOS at the Fermi surface $\Pi(0, 0) = D(\mu)$. We would like to remind the reader that the screening of the Coulomb potential at large distances is determined by the magnitude of the Thomas-Fermi wave vector $k_F = (4\pi e^2/\kappa) \Pi(0, 0)$. When the Fermi level lies between Landau levels (that corresponds to an integer filling) $\Pi(0, 0)$ reaches a minimum (zero for $T = 0, \Gamma_N = 0$) and the screening is minimal. On the other hand, if the Fermi level is inside a Landau level, then the screening is maximal. The corresponding screening properties of electronic environment on an isolated charged impurity in a magnetic field were recently observed experimentally in monolayer graphene in Ref. [29]. It was demonstrated that, in the presence of a magnetic field, the strength of the impurity can be tuned by controlling the occupation of Landau levels with a gate voltage. It would be interesting to repeat such experiments in multilayer graphene.

The static polarization functions Eqs. (33) and (34) simplify in the case of zero width Landau levels $\Gamma_N = 0$ when they are described by Eqs. (35) and (36). The quantity $\Pi(0, 0)$, which is related to the Thomas-Fermi screening vector, is given in the clean ABC-stacked multilayer graphene by the expression

$$\Pi(0, 0) = \frac{1}{4\pi l^2 T} \sum_{N=n}^{\infty} \sum_{\lambda=\pm1} \frac{1}{\text{ch}^2 \left( \frac{\mu - \lambda M_N}{2T} \right)} + \frac{1}{4\pi l^2 T} \sum_{\lambda=\pm1}^{n} \frac{n}{\text{ch}^2 \left( \frac{\mu + \Delta}{2T} \right)}. \quad (33)$$

The weak-magnetic-field limit ($l \rightarrow \infty$) of the above expression can be obtained by replacing $N \rightarrow k^2 l^2 / 2$, with the sum turning into the integral

$$\Pi(0, 0) = \frac{1}{4\pi T n(a_n)^{2/n}} \int_{-\infty}^{\infty} d\epsilon |\epsilon^2 - \Delta^2|^{1/n-1} \Theta(\epsilon^2 - \Delta^2) \cosh^2 \left( \frac{\epsilon^2}{2T} \right), \quad (34)$$

which at $T = 0$ gives the density of states of chiral multilayer graphene at the Fermi surface in the absence of the magnetic field

$$\Pi_{T=0}(0, 0) = D(\mu) = \frac{|\mu|}{n\pi \hbar^2 v^2_F} \left( \frac{\gamma^2}{\mu^2 - \Delta^2} \right)^{1-\frac{2}{n}} \Theta(\mu^2 - \Delta^2). \quad (35)$$

![FIG. 4: (Color online) $\Pi(0, 0)$ as a function of $\mu$ in the gapless case $\Delta = 0$, and magnetic field $B = 1$ T. (a) $n = 1$ ($T = 5 \cdot 10^{-3} \gamma_1$), (b) $n = 2$ ($T = 8 \cdot 10^{-4} \gamma_1$), (c) $n = 3$ ($T = 8 \cdot 10^{-4} \gamma_1$), and (d) $n = 5$ ($T = 5 \cdot 10^{-4} \gamma_1$).](image)
In Eq. (B9) are the same. Therefore, by using this result, we find that Eqs. (25) and (26) imply the following dynamical polarization functions in clean and [31] fields. Ref. [10] suggest that the LAF state is the ground state of rhombohedral trilayer graphene in the absence of external µ asymmetry of this function with respect to the change to the quantum anomalous Hall (QAH) state [32, 33] with broken time-reversal symmetry. One can observe an Eξσ layer antiferromagnetic (LAF) state [33–35] with the gap ∆ = 0 that reflects the degeneracy of this level. These results for the DOS agree with those discussed in Refs. [30] (from the zero-field DOS given by Eq. (35): for large µ it grows for n = 1, becomes constant for n = 2, and decreases for n ≥ 3. The strength of the peak corresponding to the zero energy LL also increases as the number of layers grows that reflects the degeneracy of this level. These results for the DOS agree with those discussed in Refs. [31] (n = 1) and [31] (n = 2, 3).

In Fig. 5 we show the dependence of the dimensionless quantity Π(0, 0) = (2h2vF 2/γ1)Π(0, 0) for n = 1, 2, 3, 5 in gapless rhombohedral graphene. Comparing the behavior of the DOS as the number of layers n increases one can see that the LLL contribution is enhanced because Landau levels are getting denser near zero energy for n > 2 (notice the change of scale of the vertical axis). Furthermore, the DOS envelope function itself reflects the behavior of the zero-field DOS given by Eq. [35]: for large µ it grows for n = 1, becomes constant for n = 2, and decreases for n ≥ 3. We note that the recent experimental data in Ref. [10] suggest that the LAF state is the ground state of rhombohedral trilayer graphene in the absence of external fields.

B. Dynamical screening

In this section, we analyze the dynamical screening in clean rhombohedral graphene. For ΓN = 0 all denominators in Eq. [35] are the same. Therefore,

\[ Z^{\lambda'}_{N,N'}(\omega, 0, \mu, T) + Z^{-\lambda',-\lambda}_{N,N'}(\omega, 0, \mu, T) = Z^{\lambda}_{N,N}(\omega, 0, \mu, T) - Z^{-\lambda',-\lambda}_{N,N'}(\omega, 0, \mu, T) = n_F(\lambda' M_{N'}) - n_F(\lambda M_N). \] (36)

By using this result, we find that Eqs. [26] and [26] imply the following dynamical polarization functions in clean rhombohedral graphene:

\[ \Pi_{11}(\omega, k) = -\frac{e^{-g}}{4\pi l^2} \sum_{N,N'=0}^{\infty} (-1)^{N+N'} \sum_{\lambda,\lambda'=\pm 1} \frac{n_F(\lambda M_N) - n_F(\lambda' M_{N'})}{M_N M_{N'}(\lambda M_N - \lambda' M_{N'}) - \omega} \]
\[
\times \left[ (M_N - \lambda \Delta)(M_{N'} - \lambda' \Delta)L_{N,N'}^{y,-N'}(y)L_{N,N'}^{y,-N}(y) + (M_N + \lambda \Delta)(M_{N'} + \lambda' \Delta)L_{N,N'}^{y,-N'}(y)L_{N,N'}^{y,-N}(y) \right],
\]

(37)

\[
\Pi_{1n}(\omega, k) = -\frac{e^{-\gamma^2 \omega^2}}{2\pi i^2} \sum_{N, N'} \frac{(-1)^{N+N'} N!}{(N-n)!} \left( L_{N,N'}^{y,-N}(y)L_{N,N'}^{y,-N'}(y) \right.
\times \sum_{\lambda, \lambda' = \pm 1} \lambda \lambda' (n_F (\lambda M_N) - n_F (\lambda' M_{N'})) \lambda M_N \lambda M_{N'} (\lambda M_N - \lambda' M_{N'} - \omega),
\]

(38)

The three-dimensional (3D) plot of dimensionless dynamical polarization function \( \bar{\Pi} = \frac{2e^2}{\gamma_1} \Pi \) for ABC-stacked trilayer graphene is presented in Fig. 6. As is seen, the polarization is maximal at small frequency and momentum and decreases with the increase of \( \omega \). In Fig. 7 we plot the dimensionless screened Coulomb interactions \( \bar{V}_{\text{eff}}(\omega, k) = V_{\text{eff}}(\omega, k)\kappa \gamma_1/(2\pi e^2 \hbar v_F) \) and \( \bar{V}_{13,\text{eff}}(\omega, k) = V_{13,\text{eff}}(\omega, k)\kappa \gamma_1/(2\pi e^2 \hbar v_F) \) in gapless trilayer graphene at fixed energy \( \omega = 0.05 \gamma_1 \) with \( \kappa = 5 \). For comparison, we display also the dimensionless bare intralayer, \( \bar{V}(k) = V(k)\kappa \gamma_1/(2\pi e^2 \hbar v_F) \), and interlayer, \( \bar{V}_{13}(k) = V_{13}(k)\kappa \gamma_1/(2\pi e^2 \hbar v_F) \), Coulomb interactions. As one can see, the dynamical polarization strongly reduces the effective potentials.

![Figure 6](image1)

![Figure 7](image2)

\[\Pi(\omega, y) \approx A + By,\]

(39)
where

\[
A = -\frac{2i}{\pi l^2 \omega} \sum_{N=0}^{\infty} \sum_{\lambda=\pm 1}^{\Gamma_N} \frac{Z_N^\lambda(\omega, \Gamma, \mu, T) + (\mu \rightarrow -\mu)}{\omega + 2i \Gamma_N} \sum_{\lambda'=\pm 1} \left[ Z_N^\lambda(\omega, \Gamma, \mu, T) + (\mu \rightarrow -\mu) \right],
\]

\[
B = \frac{1}{\pi l^2} \sum_{N=0}^{\infty} \sum_{\lambda, \lambda'=\pm 1} \left[ 2N + 1 - n \left( 1 + \lambda \frac{\Delta}{M_N} \right) \right] S(N, N, \lambda, \lambda, \omega) \]

\[
- \frac{1}{4\pi l^2} \sum_{N=0}^{\infty} \sum_{\lambda, \lambda'=\pm 1} \left( S(N, N + 1, \lambda, \lambda', \omega) + S(N + 1, N, \lambda', \lambda, \omega) \right)
\]

\[
\times \left[ 2(N+1) \left( 1 + \lambda \lambda' \frac{M_N}{M_{N+1}} \right) - n \left( 1 + \lambda \frac{\Delta}{M_N} \right) \left( 1 + \lambda' \frac{\Delta}{M_{N+1}} \right) \right],
\]

(41)

the notations \(\sum', \sum''\) are explained after Eq. (29) and the functions \(Z\) and \(S\) are given in Appendix B. At zero scattering rate and finite \(\omega\) the coefficient \(A\) vanishes, while the coefficient \(B\) takes the form

\[
B = \frac{1}{2\pi l^2} \sum_{N=0}^{\infty} \sum_{\lambda, \lambda'=\pm 1} \frac{n(\lambda M_N - \lambda' M_{N+1})(n_F(\lambda M_N) - n_F(\lambda' M_{N+1}))}{(\lambda M_N - \lambda' M_{N+1})^2 - \omega^2}
\]

\[
\times \left[ 2(N+1) \left( 1 + \lambda \lambda' \frac{M_N}{M_{N+1}} \right) - n \left( 1 + \lambda \frac{\Delta}{M_N} \right) \left( 1 + \lambda' \frac{\Delta}{M_{N+1}} \right) \right].
\]

(42)

On the other hand, the limit \(\omega \rightarrow 0\) of the coefficient \(A\) at finite \(\Gamma_N\) is given by Eq. (29). One can see that the static long-wavelength polarization function \(\Pi(0, 0)\) in the magnetic field does not depend on the order of taking limits \(\omega \rightarrow 0\) and \(\mathbf{k} \rightarrow 0\), unlike in the absence of the magnetic field.

The strong-magnetic-field limit \((l \rightarrow 0)\) of the polarization function \(\Pi(\omega, \mathbf{k})\) depends on the ratio between the scattering rate and frequency. For \(\Gamma_N/\omega \neq 0\), the main contribution comes from the first \(n\) Landau levels and is given by the expression

\[
\Pi_{l \rightarrow 0}(\omega, y) = -\frac{1}{2\pi l^2} \sum_{N=0}^{n-1} \frac{\Gamma_N}{\omega(\omega + 2i \Gamma_N)} \sum_{\lambda=\pm 1} \left[ \psi \left( \frac{1}{2} + \frac{\lambda(\mu + \Delta) + \omega + i\Gamma_N}{2\pi iT} \right) - \psi \left( \frac{1}{2} + \frac{\lambda(\mu + \Delta) + i\Gamma_N}{2\pi iT} \right) \right].
\]

(43)

This contribution vanishes in clean rhombohedral graphene for nonzero \(\omega\). In this case, the leading at \(\mathbf{k} \rightarrow 0\) term has the form

\[
\Pi_{l \rightarrow 0}(\omega, y) = \frac{k^2 n^2}{2\pi \varepsilon n} \sum_{N=n-1}^{\infty} \frac{\sqrt{(N-n+1)!}}{N!} \frac{1}{\sqrt{N+1 + \sqrt{N-n+1}}},
\]

(44)

which is equivalent to the static long-wavelength limit of the polarization function in clean gapless graphene at zero temperature in the case when only \(n\) lower Landau levels are filled.

V. SUMMARY

In this paper, neglecting the trigonal warping effects and using the low-energy model, we have derived analytical expressions for the one-loop dynamical polarization functions \(\Pi_{11}(\omega, \mathbf{k})\) and \(\Pi_{1n}(\omega, \mathbf{k})\) in ABC-stacked \(n\)-layer graphene at finite temperature, chemical potential, quasiparticle gap, in the presence of a magnetic field and taking into account the finite width of Landau levels. The general results are given in terms of the digamma functions and generalized Laguerre polynomials and have the form of double sums over Landau levels given by Eqs. (25) and (26). These equations are a generalization of the corresponding expressions for the polarization function in monolayer graphene obtained in Ref. (30). We analyzed the intralayer and interlayer screened Coulomb potentials in chiral multilayer graphene and found that, for a number of layers less than or equal to eight, they are very well approximated by the simple expression where only the dynamical polarization function \(\Pi = \Pi_{11} + \Pi_{1n}\) is present. The derived polarization functions can be used to calculate the dispersion relation and the decay rate of magnetoplasmons as functions of temperature, impurity rate, and magnetic field.

We found that the magnetic field qualitatively changes the behavior of the polarization functions at small wave vectors \(|\mathbf{k}| \leq l^{-1}\). Indeed, while the static polarization function \(\Pi(0, \mathbf{k})\) diverges as \(\mathbf{k} \rightarrow 0\) for \(n \geq 3\) in the gapless case without magnetic field (18), it is no longer divergent in the presence of a magnetic field [see, Eq. (28)].
The long-range behavior of the screened static Coulomb potential in a magnetic field is governed by the Thomas-Fermi wave vector $k_F = (4\pi e^2/\kappa)\Pi(0,0)$, and the strength of screening is found to oscillate as a function of chemical potential or magnetic field. If both scattering rate and temperature are small, these oscillations turn into a sequence of delta-like functions and, for integer fillings, the screening is absent. This suggests a possibility to tune, for example, the strength of the impurity by controlling the occupation of Landau level states with a gate voltage. Such a possibility was demonstrated recently in experiments in monolayer graphene [29] and it would be interesting to observe the corresponding behavior in multilayer graphene.

Appendix A: Fermion propagator

We determine the Green’s function through the expansion over the eigenfunctions ($\Delta_{\xi s} \equiv \Delta$),

$$S(r, r'; \omega) = \sum_{N=0, \alpha = \pm 1} \int_{-\infty}^{\infty} dk \frac{\Psi(N, k, \alpha; x, y) \otimes \Psi^\dagger(N, k, \alpha; x', y')}{\omega - E_N \alpha}$$

$$= \frac{1 - \tau^3}{2(\omega + \Delta)} \int_{-\infty}^{\infty} dk e^{ik(y-y')}[u_0(\eta)u_0(\eta') + \ldots + u_{n-1}(\eta)u_{n-1}(\eta')] + \sum_{N=n}^{\infty} \frac{1}{\omega^2 - M_N^2} \int_{-\infty}^{\infty} dk e^{ik(y-y')}$$

$$\times \left[ (\omega + \tau^3 \Delta) \left[ \begin{array}{ccc} u_{N-n}(\eta)u_{N-n}(\eta') & 0 & 0 \\ u_N(\eta)u_N(\eta') & 0 & 0 \end{array} \right] \right] - \xi n \sqrt{M_N^2 - \Delta^2} (-i\tau^3)^n \left[ \begin{array}{ccc} 0 & u_{N-n}(\eta)u_N(\eta') \\ 0 & 0 \end{array} \right]$$

(A1)

Using the following formula 7.378 in Ref. [36],

$$\int_{-\infty}^{\infty} e^{-x^2} H_m(x + y) H_n(x + z) dx = 2^n \pi^{1/2} m! \tau^{n-m} L_m^{n-m} (-2yz), \quad m \leq n,$$  

(A2)

where $L_m^{n}(z)$ are the generalized Laguerre polynomials, we can calculate the integral over $k$,

$$\int_{-\infty}^{\infty} dk e^{ik(y-y')} u_m(\eta)u_n(\eta') = \frac{1}{2\pi i^2} \exp \left( -\frac{(r-r')^2}{4l^2} - i \frac{(x+x')(y-y')}{2l^2} \right)$$

$$\times \sqrt{\frac{2^n m!}{2^n n!}} \left( -\frac{(x-x') - i(y-y')} {2l} \right)^{n-m} L_m^{n-m} \left( \frac{(r-r')^2}{2l^2} \right).$$

(A3)

The Green’s function can be represented as follows:

$$S(r, r'; \omega) = \exp(i\Phi) \tilde{S}(r - r'; \omega),$$

(A4)

where $\tilde{S}(r - r'; \omega)$ is the translation invariant part and $\Phi = \frac{ie}{\hbar c} \int r A_i^x(z) dz_i$ is the Schwinger phase, which is not translation invariant. We find

$$\tilde{S}(r - r'; \omega) = \frac{1}{2\pi i^2} e^{-z/2} \left\{ \sum_{N=0}^{\infty} \frac{1}{\omega^2 - M_N^2} \left( \omega + \tau^3 \Delta \left( \frac{1 - \tau^3}{2} L_N(z) + \frac{1 + \tau^3}{2} L_{N-n}(z) \right) \right) \right.$$  

$$- \frac{i n \xi n \alpha n}{2} L_m^{n-n}(z) \left[ \begin{array}{ccc} 0 & [(x-x') + i(y-y')]^{n} \\ 0 & [(x-x') + i(y-y')]^{n} \end{array} \right] \right\}, \quad z = \frac{(r-r')^2}{2l^2}.$$  

(A5)
For completeness, we present here the momentum space expression for the translation invariant part of the fermion Green’s function

\[
\hat{S}(k, \omega) = 2e^{-k^2l^2} \left\{ \sum_{N=0}^{\infty} \frac{(-1)^N}{\omega^2 - M_N^2} \left[ \left( \frac{1 - \frac{\tau^3}{2} L_N(2k^2l^2)}{\omega + \frac{\tau^3}{2} L_N(2k^2l^2)} \right) + (-1)^n \frac{1 + \tau^3}{2} L_{N-n}(2k^2l^2) \right] \right\}
\]

- \( (-1)^n (2\xi)^n a_n L_{N-n}(2k^2l^2) \left( \frac{(k_x + i k_y)^n}{(k_x + i k_y)^n} \right) \right\}

\[
= 2e^{-k^2l^2} \sum_{N=0}^{\infty} \frac{(-1)^N}{\omega^2 - M_N^2} \left( (-1)^n (2\xi)^n a_n L_{N-n}(2k^2l^2) \left( \frac{(k_x + i k_y)^n}{(k_x + i k_y)^n} \right) \right)
\]

(by definition \( L_{-m} = 0, \ m > 0 \)).

**Appendix B: Summation over Matsubara frequencies**

In order to find the polarization functions in momentum space, we use the following integrals:

\[
\Pi_{n,n}^{(n)}(k, \omega) = \int d^2 r e^{-ikr} e^{-z L_{N-n}(z)L_{N-n}(-z)n^2}
\]

\[
= 4\pi l^2 (2l^2)^n (-1)^n \frac{N!}{(N-n)!} \int_0^\infty dx x e^{-x^2} J_0 \left( \sqrt{2k^2l^2 x} \right) L_{N-n}^{n-1}(x^2) L_{N-n}^n(x^2)
\]

\[
= 2\pi l^2 (-1)^{N+K} (2)^n \frac{N!}{(N-n)!} e^{-y} L_{N-n}^{K-N}(y) L_{N-n}^{n-K}(y), \quad z = \frac{r^2}{2l^2}, \quad y = \frac{k^2l^2}{2},
\]

where we used Eq. (7.422.2) in Ref. [30] and the following property of the Laguerre polynomials for \( l, k \geq 0 \):

\[
L_l^k(x) = (-x)^{-k} \frac{(l+k)!}{l!} L_{l+k}(-x) \implies x^n L_{N-n}^n(x) = (-1)^n \frac{N!}{(N-n)!} L_{N-n}^{n}(x),
\]

where \( l, k \geq 0 \). (For more details of calculations of similar integrals, see Appendix A in Ref. [30].)

The dynamical polarization functions \([21]\) at finite temperature, chemical potential, and nonzero width \( \Gamma_N \) take the form

\[
\Pi_{11}(i\Omega_p, k) = -\frac{T}{\pi l^2} \sum_{m=-\infty}^{+\infty} \sum_{N, N' = 0}^{+\infty} \left( \frac{(-1)^{N+K} e^{-y}}{(i\omega_m + \mu + i\Gamma_N \text{sgn} \omega_m)^2 - M_N^2} \left( (i\omega_{m-p} + \mu + i\Gamma_N \text{sgn} \omega_{m-p})^2 - M_{N'}^2 \right) \right)
\]

\[
\times \left[ (i\omega_{m} + \mu) (i\Gamma_N \text{sgn} \omega_{m} - \Delta) (i\omega_{m-p} + \mu) (i\Gamma_N \text{sgn} \omega_{m-p} - \Delta) L_{N-N'}^{n-n'(y)} L_{N-N-n'}^{n'}(y) \right],
\]

\[
\Pi_{1a}(i\Omega_p, k) = -\frac{T}{\pi l^2} \sum_{m=-\infty}^{+\infty} \sum_{N, N' = 0}^{+\infty} \left( \frac{(-1)^{N+K} e^{-y}}{(i\omega_m + \mu + i\Gamma_N \text{sgn} \omega_m)^2 - M_N^2} \left( (i\omega_{m-p} + \mu + i\Gamma_N \text{sgn} \omega_{m-p})^2 - M_{N'}^2 \right) \right)
\]

\[
\times 2 \left( \frac{2}{N(N-1) \ldots (N-n+1)} \right) L_{N-N-n'}^{n-n'(y)} L_{N-N-n'}^{n'}(y).
\]

The summation over Matsubara frequencies is performed as usual \( T \sum_{m=-\infty}^{+\infty} f(i\omega_m + \mu) = \frac{1}{\pi r} \gamma n_F(\omega)f(\omega)d\omega \), where \( n_F(x) = \{ \exp(x/\beta) + 1 \}^{-1} \) is the Fermi distribution, with subsequent deformation of the contour over the poles of the function \( f(\omega) \). It is convenient also to use the identities

\[
\frac{1}{x^2 - b^2} = \frac{1}{2b} \left( \frac{1}{x - b} - \frac{1}{x + b} \right) = \sum_{\lambda=\pm 1} \frac{\lambda}{2b(x - \lambda b)},
\]

\[
\frac{x + a}{x^2 - b^2} = \frac{b + a}{2b} \frac{1}{x - b} - \frac{b - a}{2b} \frac{1}{x + b} = \sum_{\lambda=\pm 1} \frac{b + \lambda a}{2b(x - \lambda b)}.
\]
Thus, we arrive at the equations

\[
\begin{align*}
S_1 &= T \sum_{m=-\infty}^{\infty} \frac{1}{(i\omega_m + \mu + i\Gamma_N \text{sgn}\omega_m)^2 - M_N^2} \\
&= \sum_{\lambda, \lambda'=\pm 1} \frac{\lambda' S}{4M_N M_{N'}} \text{(B6)},
\end{align*}
\]

\[
\begin{align*}
S_2 &= T \sum_{m=-\infty}^{\infty} \frac{(i\omega_m + \mu + i\Gamma_N \text{sgn}\omega_m + \Delta)(i\omega_{m-p} + \mu + i\Gamma_N \text{sgn}\omega_{m-p} + \Delta)}{((i\omega_m + \mu + i\Gamma_N \text{sgn}\omega_m)^2 - M_N^2)((i\omega_{m-p} + \mu + i\Gamma_N \text{sgn}\omega_{m-p})^2 - M_N^2)} \\
&= \sum_{\lambda, \lambda'=\pm 1} \frac{(M_N + \lambda\Delta)(M_{N'} + \lambda'\Delta) S}{4M_N M_{N'}} \text{(B7)},
\end{align*}
\]

where

\[
\begin{align*}
S &= T \sum_{m=-\infty}^{\infty} \frac{1}{(i\omega_m + \mu + i\Gamma_N \text{sgn}\omega_m - \lambda M_N)(i\omega_{m-p} + \mu + i\Gamma_N \text{sgn}\omega_{m-p} - \lambda' M_{N'})} \text{(B8)}.
\end{align*}
\]

To evaluate the sum we expand it in terms of partial fractions and, using the summation formula,

\[
\sum_{m=0}^{\infty} \left( \frac{1}{m+a} - \frac{1}{m+b} \right) = \psi(b) - \psi(a),
\]

we obtain

\[
\begin{align*}
S(N, N', \lambda, \lambda', i\Omega_p) &= -\frac{Z_{NN'}^{\lambda,\lambda'}(i\Omega_p, \Gamma, \mu, T)}{\lambda M_N - \lambda' M_{N'} - i\Omega_p - i(\Gamma_N - \Gamma_{N'})} - \frac{Z_{NN'}^{-\lambda,\lambda'}(i\Omega_p, \Gamma, -\mu, T)}{\lambda M_N - \lambda' M_{N'} + i\Omega_p + i(\Gamma_N - \Gamma_{N'})} \\
&+ \frac{Z_{NN'}^{\lambda,\lambda'}(i\Omega_p, \Gamma, -\mu, T)}{\lambda M_N - \lambda' M_{N'} - i\Omega_p - i(\Gamma_N + \Gamma_{N'})}.
\end{align*}
\]

(B9)

where we introduced a new function

\[
Z_{NN'}^{\lambda,\lambda'}(\omega, \Gamma, \mu, T) = \frac{1}{2\pi i} \left( \psi \left( \frac{1}{2} + \frac{\mu + \omega + i\Gamma_N - \lambda M_N}{2\pi i T} \right) - \psi \left( \frac{1}{2} + \frac{\mu + \omega - \lambda' M_{N'}}{2\pi i T} \right) \right) \text{(B10)}
\]

in terms of the digamma function \(\psi(z)\). When deriving Eq. \(\text{(B9)}\) we used also the following relation

\[
Z_{NN'}^{\lambda,\lambda'}(-i\Omega_p, -\Gamma, -\mu, T) = Z_{NN'}^{-\lambda,\lambda'}(i\Omega_p, \Gamma, -\mu, T),
\]

which is easily proved by making use of the formula

\[
\psi(1-z) = \psi(z) + \pi \cot(\pi z). \text{(B12)}
\]

Thus, we arrive at the equations

\[
\Pi_{11}(i\Omega_p, y) = -\frac{e^{-y}}{4\pi T} \sum_{N,N'=0}^{\infty} \frac{(-1)^{N+N'} M_{N} M_{N'}}{M_{N} M_{N'}} \sum_{\lambda, \lambda'=\pm 1} S(N, N', \lambda, \lambda', i\Omega_p) \\
\times \left[ (M_N - \lambda\Delta)(M_{N'} - \lambda'\Delta)L_{N'}^{N'-N}(y)L_{N}^{N-N'}(y) + (M_N + \lambda\Delta)(M_{N'} + \lambda'\Delta)L_{N'}^{N-N'}(y)L_{N}^{N'-N}(y) \right], \text{(B13)}
\]

\[
\Pi_{1n}(i\Omega_p, y) = -\frac{e^{-y} \xi_n^2}{2\pi T} \sum_{N,N'=0}^{\infty} \frac{(-1)^{N+N'} M_{N} M_{N'}}{(N-n)!} L_{N'}^{N'-N}(y)L_{N}^{N-N'}(y) \sum_{\lambda, \lambda'=\pm 1} \lambda' S(N, N', \lambda, \lambda', i\Omega_p). \text{(B14)}
\]

Making the analytical continuation from Matsubara frequencies by replacing \(i\Omega_p \to \omega + i0\), we obtain Eqs. 25 and 26 in the main text.
Appendix C: The polarization functions in the static limit

Taking the limit $\omega \to 0$ in Eqs. (25) and (26) and using Eq. (B10), it is not difficult to see that the third term in Eq. (B9) vanishes. Then, for $\lambda N \neq \lambda' N'$, $S$ is

$$S(\lambda N \neq \lambda' N') = -\frac{1}{\pi} \Im \left\{ \psi \left( \frac{1}{2} + \frac{\Gamma_N}{2\pi T} + \frac{\mu - \lambda M_N}{2\pi iT} \right) - \psi \left( \frac{1}{2} + \frac{\Gamma'_{N'}}{2\pi T} + \frac{\mu - \lambda' M_{N'}}{2\pi iT} \right) \right\}$$

(C1)

For $\lambda N = \lambda' N'$, Eq. (B9) implies for $\omega \to 0$

$$S = -\frac{1}{2\pi^2 T} \Re \psi' \left( \frac{1}{2} + \frac{\Gamma_N}{2\pi T} + \frac{\mu - \lambda M_N}{2\pi iT} \right).$$

(C2)

Thus, we have the following static polarization functions:

$$\Pi_{11}(0, y) = \frac{e^{-y}}{8\pi^2 T^2} \sum_{N=0}^{\infty} \sum_{\lambda = \pm 1} \frac{1}{M_N^2} \Re \psi' \left( \frac{1}{2} + \frac{\Gamma_N}{2\pi T} + \frac{\mu - \lambda M_N}{2\pi iT} \right) \left( (M_N - \lambda\Delta) (L_N(y))^2 + (M_N + \lambda\Delta) (L_{N-n}(y))^2 \right)$$

$$+ \frac{e^{-y}}{4\pi^2 T^2} \sum_{N,N'=0}^{\infty} \sum_{\lambda,\lambda' = \pm 1} \frac{\psi^{N,N'}}{M_N M_{N'}} \Im \left\{ \psi \left( \frac{1}{2} + \frac{\Gamma_N}{2\pi T} + \frac{\mu - \lambda M_N}{2\pi iT} \right) - \psi \left( \frac{1}{2} + \frac{\Gamma'_{N'}}{2\pi T} + \frac{\mu - \lambda' M_{N'}}{2\pi iT} \right) \right\}$$

$$\times \left[ (M_N - \lambda\Delta)(M_{N'} - \lambda'\Delta) \left( \frac{N_+}{N_+} \right) \left( L_{N-N'}(y)^2 \right) + (M_N + \lambda\Delta)(M_{N'} + \lambda'\Delta) \left( \frac{N_-}{N_-} \right) \left( L_{N-N'}(y)^2 \right) \right]$$

(C3)

$$\Pi_{1n}(0, y) = \frac{e^{-y}}{8\pi^2 T^2} \sum_{N=n}^{\infty} \sum_{\lambda = \pm 1} \frac{2\sigma^2_\rho}{M_N^2} \frac{N!}{(N-n)!} L_N(y) L_{N-n}(y) \Re \psi' \left( \frac{1}{2} + \frac{\Gamma_N}{2\pi T} + \frac{\mu - \lambda M_N}{2\pi iT} \right)$$

$$+ \frac{e^{-y}}{4\pi^2 T^2} \sum_{N,N'=n}^{\infty} \sum_{\lambda,\lambda' = \pm 1} \frac{2\sigma^2_\lambda \lambda'}{M_N M_{N'}} \frac{N_+!}{(N_+ - n)!} \left( L_{N-N'}(y)^2 \right) \Im \left\{ \psi \left( \frac{1}{2} + \frac{\Gamma_N}{2\pi T} + \frac{\mu - \lambda M_N}{2\pi iT} \right) - \psi \left( \frac{1}{2} + \frac{\Gamma'_{N'}}{2\pi T} + \frac{\mu - \lambda' M_{N'}}{2\pi iT} \right) \right\}$$

(C4)

where $N_+ = \min\{N, N'\}$, $N_- = \max\{N, N'\}$, and we used also Eq. (B3). We note that the last term in the second curly brackets in Eq. (C3) is considered to be equal identically zero for $N_+ - n < 0$. The expressions (C3) and (C4) are obviously real functions and, by using the formulas

$$\Im \psi ' \left( \frac{1}{2} + \frac{\mu - \lambda M_N}{2\pi iT} \right) = \frac{\pi}{2} \left( 1 - 2n_F (\lambda M_N) \right),$$

(C5)

$$\Re \psi' \left( \frac{1}{2} + \frac{\mu - \lambda M_N}{2\pi iT} \right) = \frac{\pi^2}{2} \frac{1}{\cosh^2 \left( \frac{\mu - \lambda M_N}{2\pi iT} \right)},$$

(C6)
they give the following static polarization functions in clean rhombohedral graphene:

\[
\Pi_{11}(0, y) = -\frac{e^{-y}}{4\pi l^2} \sum_{N,N'=-n}^{N,N'=n} \sum_{\lambda,\lambda'=\pm 1} \frac{n_F(\lambda M_N) - n_F(\lambda' M_{N'})}{\lambda M_N - \lambda' M_{N'}} \times y^{N-N'} \left[ (M_N - \lambda \Delta)(M_{N'} - \lambda' \Delta) \left( \frac{N_\text{<}}{N_\text{>}} \right)^2 \left( L_{N_\text{<}}^{N-N'}(y) \right)^2 \right. \\
+ \left. (M_N + \lambda \Delta)(M_{N'} + \lambda' \Delta) \left( \frac{N_\text{<}-n}{N_\text{>}-n} \right)! \left( L_{N_\text{<}-n}^{N-N'}(y) \right)^2 \right] \\
- \frac{e^{-y}}{16\pi l^2 T} \sum_{N=-n}^{N=n} \sum_{\lambda=\pm 1} \left( 1 - \frac{\lambda \Delta}{M_N} \right) \frac{n_F(\lambda M_N) - n_F(-\Delta)}{\lambda M_N + \Delta} \sum_{K=0}^{n-1} y^{N-K} \frac{K!}{N!} \left( L_{N-K}^N(y) \right)^2 \\
+ \frac{e^{-y}}{4\pi l^2 T} \sum_{N=-n}^{N=n} \sum_{\lambda=\pm 1} \frac{1}{\text{ch}^2 \left( \frac{\mu - \lambda M_N}{2T} \right)} \sum_{N',N'=0}^{N',N'=n} y^{N-N'} \left( \frac{N_\text{<}}{N_\text{>}} \right)! \left( L_{N_\text{<}}^{N-N'}(y) \right)^2, 
\]

\[
\Pi_{1n}(0, y) = -\frac{e^{-y}}{16\pi l^2 T} \sum_{N=-n}^{N=n} \sum_{\lambda=\pm 1} \left( 2E_n^2 \right) \frac{M_N}{\left( N-n \right)!} L_N(y) L_{N-n}(y) \frac{1}{\text{ch}^2 \left( \frac{\mu - \lambda M_N}{2T} \right)} \\
- \frac{e^{-y}}{4\pi l^2 T} \sum_{N,-n}^{N,n} \sum_{\lambda,\lambda'=\pm 1} \left( 2E_n^2 \lambda \lambda' \right) \frac{M_N M_{N'}}{\left( N_\text{>}-n \right)!} \frac{\left( N_\text{<} \right)!}{\left( N_\text{>}-n \right)!} y^{N-N'} L_{N_\text{<}}^{N-N'}(y) L_{N_\text{<}-n}^{N-N'}(y) \\
\times \frac{n_F(\lambda M_N) - n_F(\lambda' M_{N'})}{\lambda M_N - \lambda' M_{N'}}.
