Abstract

We introduce a new class of Backward Stochastic Differential Equations in which the $T$-terminal value $Y_T$ of the solution $(Y, Z)$ is not fixed as a random variable, but only satisfies a weak constraint of the form $E[Ψ(Y_T)] \geq m$, for some (possibly random) non-decreasing map $Ψ$ and some threshold $m$. We name them BSDEs with weak terminal condition and obtain a representation of the minimal time $t$-values $Y_t$ such that $(Y, Z)$ is a supersolution of the BSDE with weak terminal condition. It provides a non-Markovian BSDE formulation of the PDE characterization obtained for Markovian stochastic target problems under controlled loss in Bouchard, Elie and Touzi [2].

We then study the main properties of this minimal value. In particular, we analyze its continuity and convexity with respect to the $m$-parameter appearing in the weak terminal condition, and show how it can be related to a dual optimal control problem in Meyer form. These last properties generalize to a non Markovian framework previous results on quantile hedging and hedging under loss constraints obtained in Föllmer and Leukert [6, 7], and in Bouchard, Elie and Touzi [2].

Key words: Backward stochastic differential equations, optimal control, stochastic target.

1 Introduction

Solving a backward stochastic differential equation (hereafter BSDE), with terminal data \( \xi \in L^2(F_T) \) and driver \( g \), consists in finding a pair of predictable processes \((Y, Z)\), with certain integrability properties, such that the dynamics of \( Y \) satisfies
\[
dY_t = -g(t, Y_t, Z_t)dt + Z_t dW_t \quad \text{and} \quad Y_T = \xi
\]
where \( W \) denotes a standard Brownian motion. It can be rephrased in: find an initial data \( Y_0 \) and a control process \( Z \) such that the solution \( Y^Z \) of the controlled stochastic differential equation
\[
Y^Z_t = Y_0 - \int_0^t g(s, Y^Z_s, Z_s)ds + \int_0^t Z_s dW_s, \quad 0 \leq t \leq T, \quad (1.1)
\]
satisfies \( Y^Z_T = \xi \). In cases where the previous problem does not admit a solution, a weaker formulation is to find an initial data \( Y_0 \) and a control \( Z \) such that
\[
Y^Z_T \geq \xi \quad \mathbb{P} - \text{a.s.} \quad (1.2)
\]
In most applications, one is interested in the minimal initial condition \( Y_0 \) and in the associated control \( Z \). This is for instance the case in the financial literature in which \( Y_0 \) represents the cost of the cheapest super-replication strategy for the contingent claim \( \xi \), and \( Z \) provides the associated hedging strategy, see e.g. [5].

Motivated by situations where this minimal value \( Y_0 \) is too large for practical applications, it was suggested to relax the strong constraint (1.2) into a weaker one of the form
\[
E[\ell(Y^Z_T - \xi)] \geq m, \quad (1.3)
\]
where \( m \) is a given threshold and \( \ell \) is a non-decreasing map. For \( \ell(x) = 1_{\{x \geq 0\}} \), this corresponds to matching the criteria \( Y^Z_T \geq \xi \) at least with probability \( m \). In financial terms, this is the so-called quantile hedging problem, see [6]. More generally, \( \ell \) is viewed as a loss function, one typical example being \( \ell(x) := -x^q \) with \( q \geq 1 \), see [7] for general non-Markovian but linear dynamics. Such problems were coined “stochastic target problems with controlled loss” by [2] who consider a non-linear Markovian formulation in a Brownian diffusion setting, see also [8] for the jump diffusions setting.

The aim of this paper is to study the non-linear non-Markovian setting in which the terminal constraint is of the form
\[
E[\Psi(Y^Z_T)] \geq m, \quad (1.4)
\]
In the above, \( m \in \mathbb{R} \) and \( \Psi \) is a (possibly random) non-decreasing real-valued map. Our problem can then be written as
\[
\text{Find the minimal } Y_0 \text{ such that (1.1) and (1.4) hold for some } Z. \quad (1.5)
\]
This leads to the introduction of a new class of BSDEs which we call BSDEs with weak terminal condition. More precisely, we refer to this problem by saying that we want to solve
\[\text{In fact, their original formulation also imposes a budget constraint constraint } Y^Z_T \geq 0 \quad \mathbb{P} - \text{a.s., which can be taken into account by imposing a criteria of the form (1.4) with } \Psi(Y^Z_T) := 1_{\{Y^Z_T \geq 0\}} - \infty 1_{\{Y^Z_T < 0\}}.\]
the BSDE with driver $g$ and weak terminal condition $(\Psi, m)$ to insist on the fact that the terminal condition $Y^Z_T$ is not fixed as a random variable, but only has to satisfy the weak constraint (1.4).

The first step in our analysis lies in a reformulation based on the martingale representation theorem, as suggested in [2]. More precisely, if $Y_0$ and $Z$ are such that (1.4) holds, then the martingale representation theorem implies that we can find an element $\alpha$ in the set $A_0$, of predictable square integrable processes, such that

$$\Psi(Y^Z_T) \geq M^\alpha_T := m + \int_0^T \alpha_s dW_s.$$  

On the other hand, since $\Psi$ is non-decreasing, one can introduce its left-continuous inverse $\Phi$ and note that the solution $(Y^\alpha, Z^\alpha)$ of the BSDE

$$Y^\alpha_t = \Phi(M^\alpha_T) + \int_t^T g(s, Y^\alpha_s, Z^\alpha_s) ds - \int_t^T Z^\alpha_s dW_s, \quad 0 \leq t \leq T,$$  

(1.6)

actually solves (1.1) and (1.4). We indeed show that the solution of (1.5) is given by

$$\inf \{Y^\alpha_0, \alpha \in A_0 \}.$$  

(1.7)

This leads to study its dynamical counterpart

$$\mathcal{Y}^\alpha := \text{essinf}\{Y^\alpha_{\tau}, \alpha' \in A_0 \text{ s.t. } \alpha' = \alpha \text{ on } [0, \tau]\}, \quad 0 \leq \tau \leq T.$$  

(1.8)

We verify that the family $\{\mathcal{Y}^\alpha, \alpha \in A_0\}$ satisfies a dynamic programming principle which can be seen as a counterpart of the geometric dynamic programming principle of [15] used in [2]. In particular, this implies that $\{\mathcal{Y}^\alpha, \alpha \in A_0\}$ is a $g$-submartingale family to which we can apply the non-linear Doob-Meyer decomposition of [11]. This provides a representation of the family $\{\mathcal{Y}^\alpha, \alpha \in A_0\}$ in terms of minimal supersolutions to a family of BSDEs with driver $g$ and (strong) terminal conditions $\{\Phi(M^\alpha_T), \alpha \in A_0\}$. This representation allows in particular to characterize the family $\{\mathcal{Y}^\alpha, \alpha \in A_0\}$ uniquely. Under additional convexity assumptions on the coefficients $g$ and $\Phi$, we observe that the essential infimum in (1.8) is attained. Hence, there exists an optimal $\hat{\alpha} \in A_0$ such that solving the BSDE with weak terminal condition $(\Psi, m)$ boils down to solving the BSDE with dynamics (1.6) and strong terminal condition $\Phi(M^\hat{\alpha}_T)$. In a Markovian framework, our approach provides in particular a BSDE formulation for the PDEs derived in [2].

We then study in details important properties of this family and focus in particular on the regularity of $\mathcal{Y}^\alpha$ with respect to the threshold parameter $m$. We exhibit, under weak conditions, a stability property of the solution with respect to the variations of the parameter $m$. We also observe that $\mathcal{Y}^\alpha$ is convex with respect to the threshold parameter. This observation allows us in particular to conclude that $\Phi$ (whenever it is deterministic) can be replaced by its more regular convex envelope in order to compute $\mathcal{Y}^\alpha$ on $[0, T)$. This was already observed in the restrictive Markovian setting of [2], in which it is proved by using PDE technics. We provide here a pure probabilistic argument. Similarly, it was also observed in [6], [7] and [2] that (1.5) admits a dual linear problem when $g$ is linear. We extend this result via probabilistic arguments to the semi-linear setting, for which the dual
formulation takes the form of a stochastic control problem in Meyer form.

The rest of the paper is organized as follows. In Section 2, we provide a precise formulation for (1.5) and relate this problem to a $g$-submartingale family satisfying a dynamic programming principle. Attainability of the optimal control $\hat{\alpha} \in A_0$ is also discussed. Section 3 collects the continuity and convexity properties as well as the dual formulation of the problem. Finally, Section 4 contains the proof of the BSDE representation for $\{Y^\alpha, \alpha \in A_0\}$.

We close this introduction with a series of notations that will be used all over this paper. Let $d \geq 1$ and $T > 0$ be fixed. We denote by $W := (W_t)_{t \in [0,T]}$ a $d$-dimensional Brownian motion defined on a probability space $(\Omega, \mathcal{F}, \mathbb{P})$ with $\mathbb{P}$-augmented natural filtration $\mathbb{F} = (\mathcal{F}_t)_{t \in [0,T]}$. The components of $W$ will be denoted by $W = (W^1, \cdots, W^d)$ and $E$ will stand for the expectation with respect to $\mathbb{P}$. For simplicity, we assume that $\mathcal{F} = \mathcal{F}_T$. Throughout the paper we will make use of the following spaces.

- $L_p(U, \mathcal{G})$ denotes the set of $p$-integrable $\mathcal{G}$-measurable random variables with values in $U$, $p \geq 0$, $U$ a Borel set of $\mathbb{R}^n$ for some $n \geq 1$ and $\mathcal{G} \subset \mathcal{F}$. When $U$ and $\mathcal{G}$ can be clearly identified by the context, we omit them. This will be in particular the case when $\mathcal{G} = \mathcal{F}$.
- $\mathcal{T}$ denotes the set of $\mathcal{F}$-stopping times in $[0, T]$. For $\tau_1 \in \mathcal{T}$, $\mathcal{T}_{\tau_1}$ is the set of stopping times $\tau_2$ in $\mathcal{T}$ such that $\tau_2 \geq \tau_1$ $\mathbb{P}$-a.s. The notation $E_\tau[\cdot]$ stands for the conditional expectation given $\mathcal{F}_\tau$, $\tau \in \mathcal{T}$.
- $S_2$ denotes the set of $\mathbb{R}$-valued, càdlàg$^2$ and $\mathcal{F}$-adapted stochastic processes $X = (X_t)_{t \in [0,T]}$ such that $\|X\|_{S_2} := E[\sup_{t \in [0,T]} |X_t|^2]^{1/2} < \infty$.
- $H_2$ denotes the set of $\mathbb{R}^n$-valued, $\mathcal{F}$-predictable stochastic processes $X = (X_t)_{t \in [0,T]}$ such that $\|X\|_{H_2} := E \left[ \int_0^T |X_t|^2 \, dt \right]^{1/2} < \infty$. In the following, the dimension $n$ will be given by the context.
- $K_2$ denotes the set of non-decreasing $\mathbb{R}$-valued and $\mathcal{F}$-adapted stochastic processes $X = (X_t)_{t \in [0,T]}$ such that $\|X\|_{S_2} < \infty$.

Inequalities between random variables are understood in the $\mathbb{P}$-a.s.-sense.

2 BSDE with weak terminal condition

2.1 Definitions and problem reformulation

We first define the main object of this paper.

**Definition 2.1 (Solution to a BSDE with weak terminal condition).** Given a measurable map $\Psi : \mathbb{R} \times \Omega \to U$, with $U \subset \mathbb{R} \cup \{-\infty\}$, $\tau \in \mathcal{T}$ and $\mu \in L_0(U, \mathcal{F}_\tau)$, we say that

[^2]: right-continuous with left limits
\((Y, Z) \in S_2 \times H_2\) is a supersolution of the BSDE with generator \(g : \Omega \times [0, T] \times \mathbb{R} \times \mathbb{R}^d \to \mathbb{R}\) and weak terminal condition \((\Psi, \mu, \tau)\), in short BSDE\((g, \Psi, \mu, \tau)\), if for any \(0 \leq s \leq t \leq T\),

\[
Y_s \geq Y_t + \int_s^t g(r, Y_r, Z_r)dr - \int_s^t Z_r dW_r, \quad \text{and} \quad E_\tau[\Psi(Y_T)] \geq \mu. \tag{2.1}
\]

Before discussing the well-posedness of Equation (2.1)-(2.2), let us emphasize that the difference with classical BSDEs lies in the fact that we do not prescribe a terminal condition to \(Y\) in the classical \(\mathbb{P}\) – a.s.-sense but only impose a weak condition in expectation form (which justifies the terminology of BSDE with weak terminal condition). Even if we were asking for equalities in (2.1)-(2.2), this would obviously be too weak to expect uniqueness, as any random variable \(\xi\) satisfying \(E_\tau[\Psi(\xi)] = \mu\) could serve as a terminal condition.

However, when \(\Psi\) is non-decreasing, the set

\[
\Gamma(\tau, \mu) := \{Y_\tau : (Y, Z) \in S_2 \times H_2\ \text{is a supersolution of BSDE}(g, \Psi, \mu, \tau)\}, \tag{2.3}
\]

defined for any \(\tau \in T\) and \(\mu \in L_0(U, \mathcal{F}_\tau)\), can be characterized by its lower-bound, whenever it is achieved.

Throughout the paper, we shall restrict to the case where \(g\) is Lipschitz continuous with linear growth, \(\Psi^+\) is bounded, and the domain of \(\Psi\) is bounded from below, in order to avoid un-necessary technicalities.

**Standing Assumption \((H_\Psi)\):** For \(\mathbb{P}\) – a.e. \(\omega \in \Omega\), the map \(y \in \mathbb{R} \mapsto \Psi(\omega, y)\) is non-decreasing, right-continuous, valued in \([0, 1] \cup \{-\infty\}\), and its left-continuous inverse \(\Phi(\omega, \cdot)\) satisfies \(\Phi : \Omega \times [0, 1] \mapsto [0, 1]\) is measurable.

By left-continuous inverse we mean the left-continuous map defined for \(\omega\) fixed by

\[
\Phi(\omega, x) := \inf\{y \in \mathbb{R} : \Psi(\omega, y) \geq x\},
\]

which satisfies

\[
\Phi \circ \Psi \leq \text{Id} \leq \Psi \circ \Phi. \tag{2.4}
\]

The left-hand side follows from the definition of \(\Phi\), the right-hand side holds by right-continuity of \(\Psi\). Note that the above assumption implies \(\Psi(\omega, \cdot) = -\infty\) on \((-\infty, 0)\) and \(\Psi(\omega, \cdot) = 1\) on \([1, \infty)\). In particular, the constraint in expectation (2.2) implies \(Y_T \geq 0\) \(\mathbb{P}\) – a.s. Obviously the set \([0, 1]\) is chosen for ease of notations and can be replaced by any closed interval.

**Standing Assumption \((H_g)\)** \(g\) is a measurable map from \(\Omega \times [0, T] \times \mathbb{R} \times \mathbb{R}^d\) to \(\mathbb{R}\) and \(g(\cdot, y, z)\) is \(\mathbb{F}\)-predictable, for each \((y, z) \in \mathbb{R} \times \mathbb{R}^d\). There exists a constant \(K_g > 0\) and a random variable \(\chi_g \in L_2(\mathbb{R}^+),\) such that

\[
|g(t, 0, 0)| \leq \chi_g \quad \mathbb{P} \ - \ a.s.
\]

\[
|g(t, y_1, z_1) - g(t, y_2, z_2)| \leq K_g(|y_1 - y_2| + |z_1 - z_2|) \quad \mathbb{P} \ - \ a.s.
\]

\[
\forall(t, y_i, z_i) \in [0, T] \times \mathbb{R} \times \mathbb{R}^d, \ i = 1, 2.
\]
Let \( A_{\tau,\mu} \) denote the set elements \( \alpha \in H_2 \) such that

\[
M^{(\tau,\mu),\alpha} := \mu + \int_{\tau}^{\tau^\vee} \alpha_s dW_s \quad \text{takes values in } [0, 1].
\]  

(2.5)

Then, (2.2) is equivalent to \( \Psi(Y_T) \geq M^{(\tau,\mu),\alpha}_T \) for some \( \alpha \in A_{\tau,\mu} \). In view of (2.4), this is equivalent to \( Y_T \geq \Phi(M^{(\tau,\mu),\alpha}_T) \) for some \( \alpha \in A_{\tau,\mu} \). This implies that supersolutions of BSDE\((g, \Psi, \mu, \tau)\) can be characterized in terms of \( g\)-expectations whose definition is recalled below.

**Definition 2.2 (\( g\)-expectation).** Given \( \tau_2 \in \mathcal{T} \) and \( \xi \in L_2(\mathbb{R}, F_{\tau_2}) \), let \((Y, Z) \in S_2 \times H_2\) denote the solution of

\[
Y = \xi + \int_{\tau_2}^{\tau_2} g(s, Y_s, Z_s)ds - \int_{\tau_2}^{\tau} Z_s dW_s,
\]

Then, we define the (conditional) \( g\)-expectation of \( \xi \) at the stopping time \( \tau_1 \leq \tau_2 \) as

\[
\mathcal{E}^g_{\tau_1, \tau_2}[\xi] := Y_{\tau_1}.
\]

When \( \tau_2 \equiv T \), we only write \( \mathcal{E}^g_T[\xi] \), and say that \((Y, Z)\) solves BSDE\((g, \xi)\).

Note that existence and uniqueness hold under Assumption \((H_g)\). In the following, we shall adopt the terminology of Peng [12] and call \( g\)-martingale (resp. \( g\)-submartingale) a process \( Y \) such that \( \mathcal{E}^g_{0,s}[Y_s] = Y_t \) (resp. \( \mathcal{E}^g_{0,s}[Y_s] \geq Y_t \)), for all \( t \leq s \leq T \).

**Proposition 2.1.** Fix \( \tau \in \mathcal{T}, \mu \in L_0([0, 1], F_\tau) \). Then, \((Y, Z) \in S_2 \times H_2\) is a supersolution of BSDE\((g, \Psi, \mu, \tau)\) if and only if \((Y, Z)\) satisfies (2.1) and there exists \( \alpha \in A_{\tau,\mu} \) such that \( Y_t \geq \mathcal{E}^g_t[\Phi(M^{(\tau,\mu),\alpha}_T)] \) for \( t \in [0, T] \) \( \mathbb{P} \)-a.s.

**Proof.** Let \((Y, Z)\) be a super solution of BSDE\((g, \Psi, \mu, \tau)\). Then there exists some element \( \rho \in L_0([0, 1], F_\tau) \) with \( \rho \geq \mu \), \( \mathbb{P} \)-a.s. and \( \hat{\alpha} \) in \( A_{\tau,\rho} \) such that \( \Psi(Y_T) = M^{(\tau,\rho),\hat{\alpha}}_T \). Set \( \tilde{\phi} := \inf \{ s \geq \tau, M^{(\tau,\rho),\hat{\alpha}}_s = 0 \} \). It is clear that \( \tilde{\phi} \) belongs to \( \mathcal{T} \) and that \( \alpha := \hat{\alpha} \mathbf{1}_{[0, \tilde{\phi}]} \) belongs to \( A_{\tau,\mu} \) and satisfies \( M^{(\tau,\rho),\tilde{\phi}}_T \geq M^{(\tau,\mu),\alpha}_T \), \( \mathbb{P} \)-a.s., since \( M^{(\tau,\rho),\tilde{\phi}}_T \geq 0 \) by definition of \( A_{\tau,\rho} \). The monotonicity of \( \Phi \) and (2.4) imply that

\[
Y_T \geq (\Phi \circ \Psi)(Y_T) \geq \Phi(M^{(\tau,\mu),\alpha}_T).
\]

By comparison for Lipschitz BSDEs, we obtain \( Y_t \geq \mathcal{E}^g_t[\Phi(M^{(\tau,\mu),\alpha}_T)] \) for \( t \in [0, T] \). Conversely, let \( \alpha \in A_{\tau,\mu} \) be such that \( Y_t \geq \mathcal{E}^g_t[\Phi(M^{(\tau,\mu),\alpha}_T)] \) for \( t \in [0, T] \) and assume that \((Y, Z)\) satisfies (2.1). Then, (2.4) implies

\[
\Psi(Y_T) \geq (\Phi \circ \Psi)(M^{(\tau,\mu),\alpha}_T) \geq M^{(\tau,\mu),\alpha}_T.
\]

Taking the conditional expectation on both sides leads to (2.2). \( \square \)

In view of Proposition 2.1, the lower bound of \( \Gamma(\tau, \mu) \) (which we recall, has been defined in (2.3)) can be expressed in terms of

\[
\mathcal{V}_\tau(\mu) := \inf_{\alpha \in A_{\tau,\mu}} \mathcal{E}^g_T[\Phi(M^{(\tau,\mu),\alpha}_T)], \quad \tau \in \mathcal{T}, \quad \mu \in L_0([0, 1], F_\tau).
\]  

(2.6)

This is the statement of the next corollary.
Corollary 2.1. \( \text{ess inf } \Gamma(\tau, \mu) = \mathcal{Y}_\tau(\mu), \forall \tau \in \mathcal{T}, \mu \in L_0([0,1], \mathcal{F}_\tau). \)

**Proof.** The fact that \( Y_\tau \in \Gamma(\tau, \mu) \) implies \( Y_\tau \geq \mathcal{Y}_\tau(\mu) \) follows from Proposition 2.1. On the other hand, the same proposition implies that each \( \mathcal{E}_T^g[\Phi(M^{(\tau,\mu)}_T)] \) with \( \alpha \in A_{\tau,\mu} \) belongs to \( \Gamma(\tau, \mu). \)

**Remark 2.1.** For later use, note that the assumptions \((H_g)\) and \((H_\Psi)\) ensure that we can find \( \eta \in S_2 \) such that \( |\mathcal{E}_T^g[\Phi(M)]| \lor |\mathcal{Y}_T(\mu)| \leq \eta_t, \) for all \( t \leq T \) and \( \mu \in L_0([0,1], \mathcal{F}_t), \) \( M \in L_0([0,1]). \) See (i) of Proposition 5.2 in the Appendix.

**Remark 2.2.** Note that \( \mathcal{Y}_\tau(\mu) = \mathcal{Y}_\tau(\mu_1)1_A + \mathcal{Y}_\tau(\mu_2)1_{A^c} \) whenever \( \mu := \mu_11_A + \mu_21_{A^c} \) for \( A \in \mathcal{F}_\tau, \mu_1, \mu_2 \in L_0([0,1], \mathcal{F}_\tau), \) and \( \tau \in \mathcal{T}. \) Indeed, \( \alpha := 1_{[\tau,T]}(\alpha_11_A + \alpha_21_{A^c}) \in A_{\tau,\mu} \) for all \( \alpha_i \in A_{\tau,\mu_i} \) with \( i = 1, 2. \) Since \( \mathcal{E}_T^g[\Phi(M^{(\tau,\mu)}_T)] = \mathcal{E}_T^g[\Phi(M^{(\tau,\mu_1,\alpha_1)}_T)1_A + \mathcal{E}_T^g[\Phi(M^{(\tau,\mu_2,\alpha_2)}_T)1_{A^c}], \) this implies \( \mathcal{Y}_\tau(\mu) \leq \mathcal{Y}_\tau(\mu_1)1_A + \mathcal{Y}_\tau(\mu_2)1_{A^c}. \) The converse inequality follows from the previous identity applied with \( \alpha_1 := \alpha 1_A \) and \( \alpha_2 := \alpha 1_{A^c} \) for any \( \alpha \in A_{\tau,\mu} \) so that \( \alpha_i \in A_{\tau,\mu_i}, \) for \( i = 1, 2. \)

**Remark 2.3.** Before going on with the study of the set \( \Gamma, \) let us notice that a similar analysis can be carried out for weak constraints of the form \( \mathcal{E}_T^h[\Psi(Y_T)] \geq \mu \) in place of \( E_\tau[\Psi(Y_T)] \geq \mu \) in (2.2), with \( \mathcal{E}_T^h \) defined as the \( h \)-expectation associated to some random map \( h \) satisfying similar conditions as \( g. \) In finance, the latter condition interprets as a risk-measure constraints, see e.g. [12], while our condition is more related to expected loss constraints, see [7]. Again, we try to avoid un-necessary additional technicalities and stick to the case \( h \equiv 0. \)

### 2.2 BSDE characterization of the minimal initial condition

The main result of this section is a BSDE characterization for the lower bound of the set \( \Gamma(\tau, \mu) \) of time-\( \tau \) initial conditions of supersolutions of BSDE\((g, \Psi, \mu, \tau). \) In particular, this extends to a non Markovian framework the PDE characterization of [2].

For ease of notations, we now fix \( m_o \in [0,1] \) and set

\[
M^{(0,m_o)}_t := M^{(0,m_o),\alpha}_t, \quad A^{(0,m_o)}_t := \{ \alpha' \in A_{\tau,M^{(0,m_o)}_T} : \alpha' = \alpha \, dt \otimes d\mathbb{P} \, \text{on } [0, T], \}
\]

\[
A_0 := A_{0,m_o} \quad \text{and} \quad \mathcal{Y}^{(0,m_o)}_t := \mathcal{Y}_t(M^{(0,m_o)}_t) \quad \text{for } \alpha \in A_0, \quad t \in [0, T],
\]

where we recall that \( M^{(0,m_o),\alpha} \) and \( A_{0,m_o} \) are given in (2.5).

**Theorem 2.1.** For any \( \alpha \in A_0, \) \( \mathcal{Y}^{(0,m_o)} \) is a \( g \)-submartingale, it is lâ€”dâ€”lâ€”ag \(^3\) on countable sets, and the following dynamic programming principle holds:

1. \( \mathcal{Y}^{(0,m_o)}_{\tau_1} = \text{ess inf}_{\alpha \in A^{(0,m_o)}_{\tau_1}} \mathcal{E}^{g}_{\tau_1,\tau_2}[\mathcal{Y}^{(0,m_o)}_{\tau_2}], \) for each \( \tau_1 \in \mathcal{T}, \tau_2 \in \mathcal{T}_{\tau_1}. \)

Under the additional assumption that

\[
m \in [0,1] \mapsto \Phi(\omega,m) \text{ is continuous for } \mathbb{P}-\text{a.e. } \omega \in \Omega,
\]

the following holds:

\(^3\)left and right-limited according to the french celebrated acronym
(ii) $\mathcal{Y}^\alpha$ is indistinguishable from a càdlàg $g$-submartingale, for each $\alpha \in A_0$.

(iii) There exists a family $(Z^\alpha, K^\alpha)_{\alpha \in A_0} \subset H_2 \times K_2$ satisfying

$$
\sup_{\alpha \in A_0} \|(Y^\alpha, Z^\alpha, K^\alpha)\|_{S_2 \times H_2 \times K_2} < \infty ,
$$

and such that, for all $\alpha \in A_0$, we have

$$
Y^\alpha = \Phi(M^\alpha_T) + \int^T_0 g(s, Y^\alpha_s, Z^\alpha_s)ds - \int^T_0 Z^\alpha_s dW_s + K^\alpha - K^\alpha_T ,
$$

and

$$
K^\alpha_{\tau_1} = \text{ess inf}_{\bar{\alpha} \in A_\tau_1} E \left[ K^\bar{\alpha}_{\tau_2} | \mathcal{F}_{\tau_1} \right] , \forall \tau_1 \in T , \tau_2 \in T_{\tau_1} ,
$$

and

$$
(Y^\alpha, Z^\alpha, K^\alpha)_{[0, \tau]} = (Y^\bar{\alpha}, Z^\bar{\alpha}, K^\bar{\alpha})_{[0, \tau]} , \forall \tau \in T , \bar{\alpha} \in A_\tau .
$$

(iv) $(Y^\alpha, Z^\alpha, K^\alpha)_{\alpha \in A_0}$ is the unique family of $S_2 \times H_2 \times K_2$ satisfying (2.8)-(2.9)-(2.10)-(2.11) for all $\alpha \in A_0$.

The proof of this theorem is reported in Section 4.

Remark 2.4. (i) The precise continuity assumption needed in the proof is : $\Phi(M^\alpha_{T_n})$ converges in $L_2$ to $\Phi(M^\alpha_T)$ whenever $\|M^\alpha_{T_n} - M^\alpha_T\|_{L_2}$ tends to 0, for any sequence $(\alpha_n)_{n} \subset A_0$. However, this condition implies that $\Phi$ is continuous, as soon as random variables with non-absolutely continuous law with respect to the Lebesgue measure might be considered (which is the case here).

(ii) We shall see in Proposition 3.3 below that $\Phi$ can be replaced by its $m$-convex envelope, under mild assumptions. In this case, the continuity assumption of the second part of Theorem 2.1 is not required anymore because the convex envelope of $\Phi$ is continuous, see Remark 3.1 below.

2.3 Representation as a BSDE with strong terminal condition

The previous section raises in particular one natural question: Does there exist an admissible control $\hat{\alpha}$ on the whole time interval $[0, T]$ allowing to match all time $t$-values of the minimal solution of a BSDE with weak terminal condition? Rephrasing, we wonder about the existence of a control $\hat{\alpha}$ in $A_0$ such that

$$
Y^\hat{\alpha}_t = \mathcal{E}^\hat{\alpha}_t \left[ \Phi(M^\hat{\alpha}_T) \right] , \quad 0 \leq t \leq T .
$$

Hereby, solving the BSDE with weak terminal condition $(\Psi, m_\alpha, 0)$ boils down to solving the classical BSDE with the optimal strong terminal one $\Phi(M^\hat{\alpha}_T)$: along the optimal path $\hat{\alpha}$, the compensator $K^{\hat{\alpha}}$ of the BSDE (2.9) must degenerate to 0.

Not surprisingly, the existence of an optimal control requires the addition of convexity assumptions on the coefficients of the BSDE. We shall therefore assume that:
(H_{conv}) For all \((\lambda, m_1, m_2, t, y_1, y_2, z_1, z_2) \in [0, 1] \times [0, 1]^2 \times [0, T] \times \mathbb{R}^2 \times [\mathbb{R}^d]^2\), the following holds \(P - a.s.:\)

\[
\Phi(\lambda m_1 + (1 - \lambda) m_2) \leq \lambda \Phi(m_1) + (1 - \lambda) \Phi(m_2)
\]

\[
g(t, \lambda y_1 + (1 - \lambda) y_2, \lambda z_1 + (1 - \lambda) z_2) \leq \lambda g(t, y_1, z_1) + (1 - \lambda) g(t, y_2, z_2)
\]

**Remark 2.6.** As detailed in Remark 3.2 below, the convexity assumption on the terminal moments, see e.g. [14, Proposition 7]: For any \(\tau \in T\), the map \(E_T^\tau[\Phi(\cdot)] : L_0([0, 1]) \to L_0\) is convex under Assumption (H_{conv}).

**Proposition 2.2.** Assume that Assumptions \((H_{conv})\) and (2.7) hold. Then, for any \((\tau, \alpha) \in T \times H_2\), there exists \(\hat{\alpha}_T^{\tau, \alpha} \in A_T^\alpha\) such that

\[
\mathcal{Y}_T^\alpha = E_T^\tau \left[ \Phi(M_T^{\hat{\alpha}_T^{\tau, \alpha}}) \right] = E_T^\tau \left[ \mathcal{Y}_T^{\hat{\alpha}_T^{\tau, \alpha}} \right], \quad \forall \tau' \in T.
\]

**Remark 2.6.** As detailed in Remark 3.2 below, the convexity assumption on the terminal map \(\Phi\) can be avoided in some cases. In particular, if \(\Phi\) is deterministic then it can be replaced by its convex envelope. Then, only the convexity assumption on \(g\) has to hold.

**Proof.** Lemma 4.1 below provides a sequence \((\alpha^n)_n\) valued in \(A_T^\alpha\) such that

\[
\mathcal{Y}_T^\alpha = \lim_{n \to \infty} \downarrow E_T^\tau \left[ \Phi(M_T^{\alpha^n}) \right], \quad P - a.s. \tag{2.12}
\]

Since the sequence \((M_T^{\alpha^n})_n\) is bounded in \([0, 1]\), we can find sequences of non-negative real numbers \((\lambda^n_i)_{i \geq 1}\) with \(\sum_{i \geq 1} \lambda^n_i = 1\), such that only a finite number of \(\lambda^n_i\) do not vanish, for each \(n\), and such that the sequence of convex combinations \((\tilde{M}_T^{\alpha^n})_n\) given by

\[
\tilde{M}_T^{\alpha^n} := \sum_{i \geq 1} \lambda^n_i M_T^{\alpha^n_i} \tag{2.13}
\]

converges \(P - a.s.\) to some \(\tilde{M}_T \in L_0([0, 1])\). By dominated convergence, the convergence holds in \(L_2\), in particular \(E_T[\tilde{M}_T] = M_T^{\alpha^n}\), and the martingale representation Theorem implies that we can find \(\hat{\alpha}_n \in A_T^\alpha\) such that \(\tilde{M}_T = M_T^{\hat{\alpha}_n}\). Using the convexity of \(\Phi\) and \(g\), see Remark 2.5, we deduce that

\[
\tilde{Y}_T^{\alpha^n} = \sum_{i \geq 1} \lambda^n_i E_T^\tau \left[ \Phi(M_T^{\alpha^n_i}) \right] \geq E_T^\tau \left[ \Phi(M_T) \right].
\]

By (2.12), \(\tilde{Y}_T^{\alpha^n} \to \mathcal{Y}_T^{\alpha^n} P - a.s.\). On the other hand, the convergence \(\tilde{M}_T^{\alpha^n} \to M_T^\alpha\) in \(L_2\) combined with the boundedness and a.s. continuity of \(\Phi\) implies that \(\tilde{Y}_T^{\alpha^n} \to \mathcal{Y}_T^{\alpha^n} \) in \(L_2\), after possibly passing to a subsequence. Therefore the convergence \(E_T^\tau \left[ \Phi(M_T^{\alpha^n}) \right] \to E_T^\tau \left[ \Phi(M_T) \right] \)

\(P - a.s.\) follows by Proposition 5.1 below. This gives \(\mathcal{Y}_T^{\alpha^n} \geq E_T^\tau \left[ \Phi(M_T^{\alpha^n}) \right],\) while the converse holds by definition of \(\mathcal{Y}_T^{\alpha^n}\).

It remains to show that \(\mathcal{Y}_T^{\alpha^n} = E_T^\tau \left[ \mathcal{Y}_T^{\hat{\alpha}_n} \right], \) for \(\tau' \in T\). To see this, first note that the above implies that \(\mathcal{Y}_T^{\alpha^n} = E_T^\tau \left[ E_T^{\tau'} \left[ \Phi(M_T^{\hat{\alpha}_n}) \right] \right] \geq E_T^\tau \left[ \mathcal{Y}_T^{\hat{\alpha}_n} \right]\) by standard comparison arguments and the fact that \(E_T^{\tau'} \left[ \Phi(M_T^{\hat{\alpha}_n}) \right] \geq \mathcal{Y}_T^{\hat{\alpha}_n}\) by definition. As above, we can find a sequence \((\hat{\alpha}^n) \in A_T^\alpha\), such that \(E_T^{\tau'} \left[ \Phi(M_T^{\hat{\alpha}^n}) \right] \to \mathcal{Y}_T^{\hat{\alpha}^n} P - a.s.\). In view of Remark 2.1, the convergence holds in \(L_2\) and Proposition 5.1 below implies

\[
\mathcal{Y}_T^{\alpha^n} \leq E_T^{\tau'} \left[ E_T^{\tau'} \left[ \Phi(M_T^{\hat{\alpha}^n}) \right] \right] \Rightarrow E_T^{\tau', \tau} \left[ \mathcal{Y}_T^{\hat{\alpha}^n} \right],
\]

where we used the fact that \(\hat{\alpha}^n \in A_T^\alpha \subset A_T^\alpha\) to obtain the left hand-side. \(\square\)
3 Main properties of the minimal initial condition process

In this section, we emphasize remarkable properties of the map \( \mathcal{Y}_t : \mu \in L_0([0,1], \mathcal{F}_t) \mapsto \mathcal{Y}_t(\mu) \), for \( t \in [0, T) \). We first derive the continuity of this map under a weak continuity assumption on \( \mathcal{E}_t^0[\Phi(\cdot)] \). Then, we verify that this map (or more precisely its l.s.c. envelope) is convex, and discuss the propagation of the convexity property to the time boundary \( T^- \). Finally, we retrieve, in this non-Markovian setting, a dual representation of the map \( \mathcal{Y}_0 \), using solely probabilistic arguments.

3.1 Continuity

Our continuity result is stated in terms of the quantities

\[
Err_t(\eta) := \text{esssup} \{ \mathcal{R}_t(M, M') : M, M' \in L_0([0,1]), E_t[|M - M'|^2] \leq \eta \},
\]

defined for \( \eta \in L_0([0,1]) \), in which

\[
\mathcal{R}_t(M, M') := |\mathcal{E}_t^0[\Phi(M)] - \mathcal{E}_t^0[\Phi(M')]|.
\]

Observe that classical a priori estimates on BSDEs ensure that \( Err_t(\eta_n) \to 0 \) as \( \eta_n \to 0 \) \( \mathbb{P} \)-a.s. with \( (\eta_n)_n \subset L_0([0,1]) \), whenever \( \Phi \) is a deterministic Lipschitz map, see e.g. Proposition 5.1 below. This observation remains valid when \( \Phi \) is simply continuous, via a classical convolution density argument for Lipschitz maps on bounded domains. The next result indicates that this property ensures the regularity of the map:

\( \mu \mapsto \mathcal{Y}_t(\mu) \).

**Proposition 3.1.** Let \( t < T, \mu_1, \mu_2 \in L_0([0,1], \mathcal{F}_t) \). Then,

\[
|\mathcal{Y}_t(\mu_1) - \mathcal{Y}_t(\mu_2)| \leq Err_t(\Delta(\mu_1, \mu_2)) + Err_t(\Delta(\mu_2, \mu_1)),
\]

where

\[
\Delta(\mu_i, \mu_j) := (1 - \frac{\mu_i}{\mu_j})1_{\{\mu_i < \mu_j\}} + \frac{\mu_i - \mu_j}{1 - \mu_j}1_{\{\mu_i > \mu_j\}}, \ i, j = 1, 2.
\]

Moreover,

\[
|\mathcal{Y}_t(\mu_1) - \mathcal{Y}_t(\mu_2)|1_{\{\mu_1 = 0\}} \leq \mathcal{R}_t(\mu_2, 0)
\]

and

\[
|\mathcal{Y}_t(\mu_1) - \mathcal{Y}_t(\mu_2)|1_{\{\mu_1 = 1\}} \leq \text{esssup} \{ \mathcal{R}_t(1, M) : M \in L_0([0,1]), E_t[|1 - M|^2] \leq 1 - \mu_2 \}.
\]

In particular, if \( Err_t(\eta_n) \to 0 \) \( \mathbb{P} \)-a.s. as \( \eta_n \to 0 \) \( \mathbb{P} \)-a.s., for all \( (\eta_n)_n \subset L_0([0,1]) \), then \( \mu \in L_0((0,1), \mathcal{F}_t) \mapsto \mathcal{Y}_t(\mu) \) is continuous for the sequential \( \mathbb{P} \)-a.s. convergence and the strong \( L_2 \) convergence.
Proof. Step 1. Fix $\mu_1, \mu_2 \in \mathbb{L}_0([0,1], \mathcal{F}_t)$. Given $\alpha_2 \in \mathbb{A}_{t,\mu_2}$, we define
\[
\lambda := \frac{1 - \mu_1}{1 - \mu_2} 1_{\{\mu_2 < \mu_1\}} + \frac{\mu_1}{\mu_2} 1_{\{\mu_1 < \mu_2\}} + 1_{\{\mu_1 = \mu_2\}},
\]
which is by construction valued in $[0,1]$. Since $M^{(t,\mu_2),\alpha_2}$ takes values in $[0,1]$,
\[
M^{(t,\mu_1),\lambda \alpha_2} = \mu_1 - \lambda \mu_2 + \lambda M^{(t,\mu_2),\alpha_2} \in [\mu_1 - \lambda \mu_2, \mu_1 + \lambda(1 - \mu_2)] \subset [0,1].
\]
In particular, $\lambda \alpha_2 \in \mathbb{A}_{t,\mu_1}$. Thus, (2.6) leads to
\[
\mathcal{Y}_t(\mu_1) \leq \mathcal{E}_t^g[\Phi(M_T^{(t,\mu_2),\alpha_2})] + (\mathcal{E}_t^g[\Phi(M_T^{(t,\mu_1),\lambda \alpha_2})] - \mathcal{E}_t^g[\Phi(M_T^{(t,\mu_2),\alpha_2})]) \quad (3.1)
\]
Besides,
\[
M_T^{(t,\mu_1),\lambda \alpha_2} - M_T^{(t,\mu_2),\alpha_2} = \mu_1 - \lambda \mu_2 + (\lambda - 1)M_T^{(t,\mu_2),\alpha_2}
\]
so that, since $M_T^{(t,\mu_2),\alpha_2}$ belongs to $[0,1]$, we have
\[
\mu_1 - 1 + \lambda(1 - \mu_2) \leq M_T^{(t,\mu_1),\lambda \alpha_2} - M_T^{(t,\mu_2),\alpha_2} \leq \mu_1 - \lambda \mu_2.
\]
In addition,
\[
\mu_1 - \lambda \mu_2 = 0, \quad \text{if } \mu_1 < \mu_2, \text{ and}
\mu_1 - 1 + \lambda(1 - \mu_2) = 0, \quad \text{if } \mu_1 \geq \mu_2.
\]
This directly leads to
\[
E_t[|M_T^{(t,\mu_1),\lambda \alpha_2} - M_T^{(t,\mu_2),\alpha_2}|] \leq \Delta(\mu_1, \mu_2).
\]
Since these two processes belong to $[0,1]$, we get
\[
E_t[|M_T^{(t,\mu_1),\lambda \alpha_2} - M_T^{(t,\mu_2),\alpha_2}|^2] \leq \Delta(\mu_1, \mu_2).
\]
Hence, the arbitrariness of $\alpha_2 \in \mathbb{A}_{t,\mu_2}$ together with (2.6) and (3.1) provides
\[
\mathcal{Y}_t(\mu_1) \leq \mathcal{Y}_t(\mu_2) + \text{Err}_t(\Delta(\mu_1, \mu_2)) .
\]
Interchanging the roles of $\mu_1$ and $\mu_2$ leads to
\[
\mathcal{Y}_t(\mu_2) \leq \mathcal{Y}_t(\mu_1) + \text{Err}_t(\Delta(\mu_2, \mu_1)) .
\]
Step 2. We next consider the case where $\mathbb{P}[\mu_1 = 0] > 0$. Without loss of generality, we can assume that $\mu_1 \equiv 0$. Fix $\alpha \in \mathbb{A}_{t,\mu_2}$. Since $\mathbb{A}_{t,\mu_1} = \{0\}$, $M_T^{(t,\mu_2),\alpha} \geq 0$ and $\Phi$ is non-decreasing, comparison implies that
\[
\mathcal{Y}_t(0) = \mathcal{E}_t^g[\Phi(0)] \leq \mathcal{E}_t^g[\Phi(M_T^{(t,\mu_2),\alpha})].
\]
In particular, $\mathcal{Y}_t(0) = \mathcal{E}_t^g[\Phi(0)] \leq \mathcal{Y}_t(\mu_2) \leq \mathcal{E}_t^g[\Phi(M_T^{(t,\mu_2),0})] = \mathcal{E}_t^g[\Phi(\mu_2)]$.

Step 3. We now consider the case where $\mathbb{P}[\mu_1 = 1] > 0$. Again, we can assume that $\mu_1 \equiv 1$ so that $\mathbb{A}_{t,\mu_1} = \{0\}$. By comparison as above, one has
\[
\mathcal{Y}_t(1) = \mathcal{E}_t^g[\Phi(1)] \geq \mathcal{Y}_t(\mu_2).
\]
On the other hand, since $M_T^{(t,\mu_2),\alpha}$ is a martingale taking values in $[0,1]$, we have
\[
E_t[|1 - M_T^{(t,\mu_2),\alpha}|^2] \leq E_t[1 - M_T^{(t,\mu_2),\alpha}] = 1 - \mu_2, \quad \alpha \in \mathbb{A}_{t,\mu_2},
\]
from which the result follows. □
3.2 Convexity

In [2] and [8], it is shown that the map \( m \in [0, 1] \mapsto \mathcal{Y}_0(m) \) is convex. This is done in a Markovian framework using PDE arguments. In this section, we provide a probabilistic proof of this result which hereby extends to our setting. The result is stated for the lower-semicontinuous envelope \( \mathcal{Y}_{t_*} \) of \( \mathcal{Y}_t \) defined as

\[
\mathcal{Y}_{t_*} := \lim_{\varepsilon \to 0^+} \text{essinf} \{ \mathcal{Y}_t(\mu') : |\mu' - \mu| \leq \varepsilon, \mu' \in \mathcal{L}_0([0, 1], \mathcal{F}_t) \},
\]

for any \( t \in [0, T] \). We refer to Proposition 3.1, the discussion before it and to (ii) of Remark 2.4 for conditions ensuring that \( \mathcal{Y}_* = \mathcal{Y} \).

We first make precise the notion of convexity adapted to our non-Markovian setting. Fix a time \( t \in [0, T] \).

**Definition 3.1** (\( \mathcal{F}_t \)-convexity).

(i) In the following, we say that a subset \( D \subset \mathcal{L}_\infty(\mathbb{R}, \mathcal{F}_t) \) is \( \mathcal{F}_t \)-convex if \( \lambda \mu_1 + (1 - \lambda)\mu_2 \in D \), for all \( \mu_1, \mu_2 \in D \) and \( \lambda \in \mathcal{L}_0([0, 1], \mathcal{F}_t) \).

(ii) Let \( D \) be an \( \mathcal{F}_t \)-convex subset of \( \mathcal{L}_\infty(\mathbb{R}, \mathcal{F}_t) \). A map \( \mathcal{J} : D \to \mathcal{L}_2(\mathbb{R}, \mathcal{F}_t) \) is said to be \( \mathcal{F}_t \)-convex if

\[
\text{Epi}(\mathcal{J}) := \{(\mu, Y) \in D \times \mathcal{L}_2(\mathbb{R}, \mathcal{F}_t) : Y \geq \mathcal{J}(\mu)\}
\]

is \( \mathcal{F}_t \)-convex.

(iii) Let \( \text{Epi}^c(\mathcal{Y}_t) \) be the set of elements of the form \( \sum_{n \leq N} \lambda_n (\mu_n, Y_n) \) with \( (\mu_n, Y_n, \lambda_n)_{n \leq N} \subset \text{Epi}(\mathcal{Y}_t) \times \mathcal{L}_0([0, 1], \mathcal{F}_t) \) such that \( \sum_{n \leq N} \lambda_n = 1 \), for some \( N \geq 1 \). We then denote by \( \overline{\text{Epi}}(\mathcal{Y}_t) \) its closure in \( \mathcal{L}_2 \). Finally, the \( \mathcal{F}_t \)-convex envelope of \( \mathcal{Y}_t \) is defined as

\[
\mathcal{Y}_t^c(\mu) := \text{essinf}\{Y \in \mathcal{L}_2(\mathbb{R}, \mathcal{F}_t) : (\mu, Y) \in \overline{\text{Epi}}(\mathcal{Y}_t)\}.
\]

We can now state the convexity property. It requires a right continuity property in time, which holds under the conditions of Theorem 2.1(ii), also recall (ii) of Remark 2.4.

**Proposition 3.2.** Assume that \( \mathcal{Y}_t(\mu) = \mathcal{Y}_{t+}(\mu) \) for any \( \mu \in \mathcal{L}_0([0, 1], \mathcal{F}_t) \) and \( t < T \). Then, the map \( \mu \in \mathcal{L}_0([0, 1], \mathcal{F}_t) \mapsto \mathcal{Y}_{t_*}(\mu) \) is \( \mathcal{F}_t \)-convex, for all \( t < T \).

**Proof.** Fix \( t \in [0, T) \) and set \( D := \mathcal{L}_0([0, 1], \mathcal{F}_t) \) for ease of notations. The proof is divided in several steps.

**Step 1.** \((\mu, \mathcal{Y}_t^c(\mu)) \in \overline{\text{Epi}}(\mathcal{Y}_t)\), for all \( \mu \in D \).

Indeed, the family \( F := \{Y \in \mathcal{L}_2(\mathbb{R}, \mathcal{F}_t) : (\mu, Y) \in \overline{\text{Epi}}(\mathcal{Y}_t)\} \) is directed downward (for every fixed element \( \mu \) in \( D \)) since \( Y^1 1_{\{Y^1 \leq Y^2\}} + Y^2 1_{\{Y^1 > Y^2\}} \in F \), by \( \mathcal{F}_t \)-convexity of \( \text{Epi}(\mathcal{Y}_t) \), for all \( Y^1, Y^2 \in F \). It then follows from [9, Proposition VI.1.1] that there exists a sequence \((Y^n)_{n\geq 1} \subset F\) such that \( Y^n \downarrow \mathcal{Y}_t^c(\mu) \) \( \mathbb{P} \)-a.s. Since \( Y^1 \) and \( \mathcal{Y}_t^c(\mu) \in \mathcal{L}_2 \), the monotone convergence Theorem implies that \( Y^n \to \mathcal{Y}_t^c(\mu) \) in \( \mathcal{L}_2 \), as \( n \) goes to infinity. The set \( \overline{\text{Epi}}(\mathcal{Y}_t) \) being closed in \( \mathcal{L}_2 \), this proves our claim.
Step 2. Let \( \eta \in S_2 \) be as in Remark 2.1. Then, \( |Y^\varepsilon_t(\mu)| \leq \eta_t \), for all \( t \leq T \) and \( \mu \in D \).

We first observe that \( Y \geq Y^\varepsilon \) by construction. Remark 2.1 thus implies that \( Y^\varepsilon_t(\mu) \leq \eta_t \).

On the other hand, let \( (Y^n_{\eta})_{n \geq 1} \) be as in the step above. We claim that it satisfies \( Y^n_{\eta} \geq -\eta_t \), for each \( n \geq 1 \). Then, the lower bound \( Y^\varepsilon_t(\mu) \geq -\eta_t \) is obtained by passing to the limit. To see this, it suffices to prove this property for any \( Y \in L_2(\mathbb{R}, \mathcal{F}_t) \) such that \( (\mu, Y) \in \overline{\text{Epi}}(Y_t) \).

But, such an element \( (\mu, Y) \) is obtained by taking the \( L_2 \) limit of elements of the form \( \sum_{n \leq N} \lambda_n(\mu_n, Y_n) \) with \( (\mu_n, Y_n, \lambda_n)_{n \leq N} \subset \text{Epi}(Y_t) \times L_0([0, 1], \mathcal{F}_t) \), such that \( \sum_{n \leq N} \lambda_n = 1 \).

Each \( Y_n \) of the latter family is bounded from below by \( -\eta_t \) by Remark 2.1, and hence so is \( Y \).

Step 3. The map \( \mu \in D \mapsto Y^\varepsilon_t(\mu) \) is \( \mathcal{F}_t \)-convex.

Fix \( \mu^1, \mu^2 \in D \) and \( \lambda \in L_0([0, 1], \mathcal{F}_t) \). Step 1 implies that \( (\mu^i, Y^\varepsilon_t(\mu^i)) \in \overline{\text{Epi}}(Y_t) \) for \( i = 1, 2 \). Clearly, \( \overline{\text{Epi}}(Y_t) \) is \( \mathcal{F}_t \)-convex. It follows that \( \lambda Y^\varepsilon_t(\mu^1) + (1-\lambda) Y^\varepsilon_t(\mu^2) \in \overline{\text{Epi}}(Y_t) \), so that \( \lambda Y^\varepsilon_t(\mu^1) + (1-\lambda) Y^\varepsilon_t(\mu^2) \geq Y^\varepsilon_t(\lambda Y^\varepsilon_t(\mu^1) + (1-\lambda) Y^\varepsilon_t(\mu^2)) \). Now, for any \( Y^* \) such that \( (\mu^i, Y^i) \in \text{Epi}(Y^\varepsilon_t) \), one has \( Y^i \geq Y^\varepsilon_t(\mu^i) \), \( i = 1, 2 \). This fact combined with the previous inequality thus implies \( \lambda Y^1 + (1-\lambda) Y^2 \geq Y^\varepsilon_t(\lambda Y^1 + (1-\lambda) Y^2) \). This means that \( \text{Epi}(Y^\varepsilon_t) \) is \( \mathcal{F}_t \)-convex.

Step 4. \( \mathcal{Y}_{\varepsilon_*}(\mu) \geq Y^\varepsilon_t(\mu) \), for all \( \mu \in D \).

Fix \( \varepsilon > 0 \) and set \( D^\varepsilon \mu := \{ \mu' \in L_0([0, 1], \mathcal{F}_t), |\mu' - \mu| \leq \varepsilon \} \). It follows from Remark 2.2 that the family \( \{\mathcal{Y}_{\varepsilon_*}(\mu') : \mu' \in D^\varepsilon \mu \} \) is directed downward. Then, we can find a sequence \( (\mu^\varepsilon_n)_{n \geq 1} \subset D^\varepsilon \mu \) such that \( \mathcal{Y}_{\varepsilon_*}(\mu^\varepsilon_n) \rightarrow Z_\varepsilon(\mu) := \text{essinf}\{\mathcal{Y}_{\varepsilon_*}(\mu') : \mu' \in D^\varepsilon \mu \} \quad \mathbb{P} - \text{a.s.} \)

Since \( (Z_\varepsilon(\mu))_{\varepsilon > 0} \) is non-decreasing, \( \lim_{N \rightarrow \infty} Z_{1/N}(\mu) = \mathcal{Y}_{\varepsilon_*}(\mu) \), recall (3.2). Note that Remark 2.1 implies that \( (\mathcal{Y}_{\varepsilon_*}(\mu^\varepsilon_1/N))_{n \geq 1} \rightarrow_{n} Z_{1/N}(\mu) \) in \( L^2 \) and define \( k_N := \min\{n \geq 1 : \|\mathcal{Y}_{\varepsilon_*}(\mu^\varepsilon_1/N) - Z_{1/N}(\mu)\|_{L^2} \leq 1/N \} \).

Then, \( (\mu^\varepsilon_1/N, \mathcal{Y}_{\varepsilon_*}(\mu^\varepsilon_1/N)) \rightarrow (\mu, \mathcal{Y}_{\varepsilon_*}(\mu)) \) in \( L^2 \) as \( N \rightarrow \infty \). Since \( \text{Epi}(\mathcal{Y}_{\varepsilon_*}) \subset \overline{\text{Epi}}(Y_t) \) and the latter is closed under \( L^2 \)-convergence, this implies that \( (\mu, \mathcal{Y}_{\varepsilon_*}(\mu)) \in \overline{\text{Epi}}(Y_t) \). We conclude by appealing to the definition of \( Y^\varepsilon_t \) in (3.3).

Step 5. \( Y^\varepsilon_t(\mu) \geq \mathcal{Y}_{\varepsilon_*}(\mu) \), for all \( \mu \in D \).

In view of Steps 3 and 4, the result of Step 5 actually proves that \( \mathcal{Y}_{\varepsilon_*} = Y^\varepsilon_t \) is \( \mathcal{F}_t \)-convex. We now proceed to the proof of Step 5 which is itself divided in two parts.

Step 5.a. It follows from Step 1, that there exists a sequence \( (\mu_n, Y_n, \lambda^N_n)_{n \geq 1, N \geq 1} \subset \text{Epi}(\mathcal{Y}_t) \times L_0([0, 1], \mathcal{F}_t) \) (3.4) such that \( \sum_{n \leq N} \lambda^N_n = 1 \), for all \( N \), and \( (\hat{\mu}_N, \hat{Y}_N) := \sum_{n \leq N} \lambda^N_n (\mu_n, Y_n) \rightarrow (\mu, Y^\varepsilon_t(\mu)) \) in \( L_2 \). (3.5)
Fix $N \geq 1$ and $\varepsilon > 0$. Let $\hat{\alpha}^N \in \mathbf{H}_2$ be such that $\hat{\mu}_N = \mu_0 + \int_0^t \hat{\alpha}_s^N \, dW_s$. Since the family $(\lambda^N_n)_{n \leq N}$ is composed of $\mathcal{F}_t$-measurable random variables summing to 1, one can find $\alpha^N \in \mathbf{H}_2$ and a random variable $\xi^N \in \mathbf{L}_2(\mathcal{F}_{t+\varepsilon})$ such that

$$\hat{\mu}_N + \int_t^{t+\varepsilon} \alpha^N_s \, dW_s = \xi^N_N \quad \text{and} \quad \mathbb{P}[\xi^N_N = \mu_n|\mathcal{F}_t] = \lambda^N_n, \quad \text{for } n \leq N. \quad (3.6)$$

Without loss of generality, we can assume that $\alpha^N = \hat{\alpha}^N$ $dt \times d\mathbb{P}$ on $[0,t]$. Then, (i) of Theorem 2.1 and Remark 2.2 yield

$$\mathcal{Y}_t(\hat{\mu}_N) = \mathcal{Y}_t^{\hat{\alpha}^N} \leq \mathcal{E}^g_{t,t+\varepsilon}(\mathcal{Y}_t^{\alpha^N}) = \mathcal{E}^g_{t,t+\varepsilon}(\mathcal{Y}_{t+\varepsilon}(\xi^N))$$

$$= \mathcal{E}^g_{t,t+\varepsilon} \left( \sum_{n \leq N} 1_{\xi^N_n = \mu_n} \mathcal{Y}_{t+\varepsilon}(\mu_n) \right). \quad (3.7)$$

We claim that

$$\liminf_{\varepsilon \to 0} \mathcal{E}^g_{t,t+\varepsilon} \left( \sum_{n \leq N} 1_{\xi^N_n = \mu_n} \mathcal{Y}_{t+\varepsilon}(\mu_n) \right) \leq \sum_{n \leq N} \lambda^N_n \mathcal{Y}_t(\mu_n). \quad (3.8)$$

Then, (3.7), (3.8), (3.4) and (3.5) lead to

$$\mathcal{Y}_t(\hat{\mu}_N) \leq \sum_{n \leq N} \lambda^N_n \mathcal{Y}_t(\mu_n) \leq \sum_{n \leq N} \lambda^N_n Y_n = \hat{Y}_N.$$ 

Appealing to (3.5), we deduce that

$$\liminf_{N \to \infty} \mathcal{Y}_t(\hat{\mu}_N) \leq \mathcal{Y}^\varepsilon_t(\mu).$$

Since $\hat{\mu}_N \to \mu$ $\mathbb{P}$ - a.s., this together with Remark 2.2 implies that

$$Z_\varepsilon(\mu) \leq \liminf_{N \to \infty} \mathcal{Y}_t(\hat{\mu}_N) = \liminf_{N \to \infty} \left( \mathcal{Y}_t(\hat{\mu}_N)1_{|\hat{\mu}_N - \mu| \leq \varepsilon} + \mathcal{Y}_t(\mu)1_{|\hat{\mu}_N - \mu| > \varepsilon} \right)$$

$$\leq \mathcal{Y}^\varepsilon_t(\mu),$$

for all $\varepsilon > 0$, where

$$\hat{\mu}_N := \hat{\mu}_N 1_{|\hat{\mu}_N - \mu| \leq \varepsilon} + \mu 1_{|\hat{\mu}_N - \mu| > \varepsilon} \in D_\varepsilon^\mu,$$

see Step 4 for the definitions of $Z_\varepsilon(\mu)$ and $D_\varepsilon^\mu$. Since $Z_\varepsilon(\mu) \uparrow \mathcal{Y}_t(\mu)$ as $\varepsilon$ goes to 0 by (3.2), this shows the required result.

**Step 5.b** It finally remains to prove the claim (3.8).

Remark 2.1 and (ii) of Proposition 5.2 in the Appendix imply that

$$\mathcal{E}^g_{t,t+\varepsilon} \left( \sum_{n \leq N} 1_{\xi^N_n = \mu_n} \mathcal{Y}_{t+\varepsilon}(\mu_n) \right) \leq E_t \left[ \sum_{n \leq N} 1_{\xi^N_n = \mu_n} \mathcal{Y}_{t+\varepsilon}(\mu_n) \right] + \eta_\varepsilon$$

$$\leq E_t \left[ \sum_{n \leq N} 1_{\xi^N_n = \mu_n} \mathcal{Y}_t(\mu_n) \right] + \eta_\varepsilon$$

$$+ \sum_{n \leq N} E_t \left[ |\mathcal{Y}_{t+\varepsilon}(\mu_n) - \mathcal{Y}_t(\mu_n)| \right],$$

14
where \( \eta \rightarrow 0 \) \( \mathbb{P} \) – a.s. as \( \varepsilon \rightarrow 0 \). The right-hand side of (3.6) then leads to

\[
\mathcal{E}_{t,t+\varepsilon}^g \left( \sum_{n \leq N} 1_{\xi_n = \mu_n} \mathcal{Y}_{t+\varepsilon}(\mu_n) \right) \leq \sum_{n \leq N} \lambda_n^N \mathcal{Y}(\mu_n) + \eta \varepsilon + \sum_{n \leq N} E_t \left[ |\mathcal{Y}_{t+\varepsilon}(\mu_n) - \mathcal{Y}(\mu_n)| \right].
\]

Recall that \( \mathcal{Y}_{t+}(\mu_n) = \mathcal{Y}(\mu_n) \) by assumption, and that \( \langle \mathcal{Y}(\mu_n) \rangle_n \) is bounded by some \( \eta \in S_2 \), see Remark 2.1. Sending \( \varepsilon \rightarrow 0 \) in the above inequality and appealing to the Lebesgue dominated convergence Theorem proves (3.8). \[\square\]

In the context of PDEs, convexity in the domain propagates up to the boundary, which leads to a boundary layer phenomenon. In [2] and [8] this translates in the fact that the natural \( T \)-time boundary condition should be stated in terms of the \( m \)-convex envelope of \( \Phi \). We observe hereafter that this property extends to our non-Markovian setting, whenever \( \Phi \) is deterministic.

We recall from Theorem 2.1 (i) that \( \mathcal{Y} \) is lådlåg on countable sets. Under the following condition, it will actually be càdlàg up to undistinguishability. As opposed to Proposition 3.2, we shall not need to impose any right-continuity for the following.

**Proposition 3.3.** Assume that \( \Phi \) is deterministic and let \( \hat{\Phi} \) denote its convex envelope. Then,

\[
\lim_{t \uparrow T} \mathcal{Y}_t^\alpha = \hat{\Phi}(M_T^\alpha) \quad \text{and} \quad \mathcal{Y}_\tau^\alpha = \operatorname{ess inf}_{\alpha' \in A_\tau} \mathcal{E}_\tau^g \left[ \hat{\Phi}(M_T^\alpha) \right],
\]

for all \( \alpha \in \mathcal{A}_0 \) and \( \tau \in T \) such that \( \tau < T \).

Before proving this result, let us make some observations.

**Remark 3.1.** Since \( \Phi \) is non-decreasing, its convex envelope is continuous on \([0,1)\). Moreover, \( \hat{\Phi} \) is left-continuous, so that \( \hat{\Phi} \) has to be continuous at 1 as well.

**Remark 3.2.** In Section 2.3, we observed that the essential infimum in the dynamic programming principle is attained whenever \( \Phi \) and \( g \) are convex. Hence, the previous proposition allows straightforwardly to avoid the convexity requirement on \( \Phi \), whenever it is deterministic.

**Remark 3.3.** The proof below can easily be adapted to the case where \( \Phi(\omega, m) = \phi(m)\xi(\omega) \) for some non-negative random variable \( \xi \) and a deterministic map \( \phi \). This is due to the fact that the \( m \)-convex envelope of \( \Phi \) is fully characterized by the convex envelope \( \hat{\phi} \) of \( \phi : \hat{\Phi}(\omega, m) = \hat{\phi}(m)\xi(\omega) \). This allows one to follow the construction used in our proof. In particular, in the quantile hedging problem of Föllmer and Leukert [6], one has \( \Phi(\omega, m) = 1_{\{m > 0\}}\xi(\omega) \) (\( m \in [0,1] \)), with \( \xi \) taking non-negative values, so that \( \hat{\Phi}(\omega, m) = m\xi(\omega) \), see also [2].

**Proof of Proposition 3.3.** We prove each assertion separately.
Step 1. By definition of the convex envelope, we can find a measurable map \( m \in [0,1] \mapsto (\varphi(m), \overline{\varphi}(m), \varepsilon(m)) \in [0,1]^3 \) such that  
\( \varphi(m) \leq m \leq \overline{\varphi}(m), \varepsilon(m)\varphi(m) + (1-\varepsilon(m))\overline{\varphi}(m) = m \) 
and  
\( \hat{\Phi}(m) = \varepsilon(m)\Phi(\varphi(m)) + (1-\varepsilon(m))\Phi(\overline{\varphi}(m)) \),

for any \( m \in [0,1] \). Let \( t_n \uparrow T \). Then, one can find \( \alpha^n \in A^n_{t_n} \) and \( \xi^n \in L_0([0,1]) \) such that \( M^n_T = M^n_{t_n} + \int_{t_n}^T \alpha^n_s dW_s = \xi^n \), where \( \mathbb{P}[\xi^n = \bar{\varphi}(M^n_{t_n})|\mathcal{F}_{t_n}] = \varepsilon(M^n_{t_n}) \) and \( \mathbb{P}[\xi^n = \overline{\varphi}(M^n_{t_n})|\mathcal{F}_{t_n}] = 1 - \varepsilon(M^n_{t_n}) \). It follows from the above and (iii) of Proposition 5.2 in the Appendix that  
\[ Y^n_{t_n} \leq E_{t_n}\left[\Phi(\xi^n)\right] + \eta_n = \hat{\Phi}(M^n_{t_n}) + \eta_n, \]

where \( \eta_n \to 0 \) as \( n \to \infty \). Since \( Y \) is càdlàg on countable sets (by Proposition 4.2), passing to the limit implies that  
\[ \lim_{n \to \infty} Y^n_{t_n} \leq \hat{\Phi}(M^0_T). \] (3.9)

We now prove the converse inequality. We use (iii) in Proposition 5.2 in the Appendix and Jensen’s inequality to deduce that  
\[ Y^{\alpha'}_{t_n} := E^g_{t_n,\mathcal{T}}[\Phi(M^{\alpha'}_T)] \geq E_{t_n}\left[\hat{\Phi}(M^{\alpha'}_T)\right] - \eta_n \geq \hat{\Phi}(M^n_{t_n}) - \eta_n, \quad \alpha' \in A^n_{t_n}, \]

where \( \eta_n \to 0 \) as \( n \to \infty \). Combining the arbitrariness of \( \alpha' \in A^n_{t_n} \) with the càdlàg property of \( Y \) on countable sets, we get that  
\[ \lim_{n \to \infty} Y^{\alpha'}_{t_n} \geq \liminf_{n \to \infty} \inf_{\alpha' \in A_{t_n}^{\alpha}} Y^{\alpha'}_{t_n} \geq \hat{\Phi}(M^0_T). \]

Step 2. It follows from Theorem 2.1 (i) that  
\[ Y^{n}_{\tau} = \inf_{\alpha' \in A^{\alpha}_{\tau}} E^g_{\tau,\mathcal{T}_{\tau\lor\tau}}[Y^{\alpha'}_{\tau\lor\tau}], \quad n \in \mathbb{N}. \]

The process \( Y^{\alpha'}_{\tau\lor\tau} \) being càdlàg on the set \( \{t_n, n \geq 1\} \), \( \lim_{n \to \infty} Y^{\alpha'}_{\tau\lor\tau} \) is well-defined and coincides with \( \lim_{n \to \infty} Y^{\alpha'}_{t_n} \). Moreover, it follows from the bound in Remark 2.1 that the convergence holds in \( L_2 \). In view of the stability result of Proposition 5.1 and Step 1. above, passing to the limit as \( n \to \infty \) leads to  
\[ Y^{\alpha}_{\tau} \leq \inf_{\alpha' \in A^{\alpha}_{\tau}} E^g_{\tau}[\lim_{n \to \infty} Y^{\alpha'}_{t_n}] = \inf_{\alpha' \in A^{\alpha}_{\tau}} E^g_{\tau}[\hat{\Phi}(M^{\alpha'}_T)]. \]

Since \( \Phi \geq \hat{\Phi} \), the reverse inequality holds by definition of \( Y^{n}_{\tau} \) in (2.6). Since \( \hat{\Phi} \) is continuous by Remark 3.1, we can now appeal to the second statement of Proposition 4.2 to assert that, up to indistinguishability, \( Y^{\alpha} \) is càdlàg, so that \( \lim_{t \uparrow T} Y^{\alpha}_t = \lim_{n \to \infty} Y^{n}_{t_n} \).

3.3 Dual representation

In this section, we provide a dual formulation for the minimal initial condition at time 0, \( m \mapsto Y_0(m) \). It requires the introduction of the Fenchel transforms of \( g \) and \( \Phi \).
We therefore define
\[ \tilde{\Phi} : (\omega, l) \in \Omega \times \mathbb{R} \mapsto \sup_{m \in [0,1]} (ml - \Phi(\omega, m)) \]
and
\[ \tilde{g} : (\omega, t, u, v) \in \Omega \times [0, T] \times \mathbb{R} \times \mathbb{R}^d \mapsto \sup_{(y, z) \in \mathbb{R} \times \mathbb{R}^d} \left( yu + z^T v - g(\omega, t, y, z) \right). \]

**Remark 3.4.** It follows from the assumption \((H_\Psi)\) that the domain of \(\tilde{g}(\omega, t, \cdot), \text{dom}(\tilde{g}(\omega, t, \cdot))\), is contained in \([-K_y, K_y]^{d+1}\) for \(\mathbb{P}\)-a.e. \(\omega \in \Omega\) and all \(t \leq T\). The assumption \((H_\Psi)\) ensures that the domain of \(\tilde{\Phi}(\omega, \cdot)\) is the whole real line, \(\mathbb{R} - \text{a.s.}\).

In the following, we denote by \(\Lambda\) the set of predictable processes \(\lambda\) with values in \(\mathbb{R} \times \mathbb{R}^d\) such that \(\lambda_t(\omega) \in \text{dom}(\tilde{g}(\omega, t, \cdot))\) for \(\text{Leb} \times \mathbb{P}\)-a.e. \((\omega, t) \in \Omega \times [0, T] \).

To \(\lambda = (\nu, \vartheta) \in \Lambda\), we associate the process \(L_\lambda\) defined by
\[ L_t^\lambda = 1 + \int_0^t L_s^\nu \, ds + \int_0^t L_s^\vartheta \, dW_s, \quad t \in [0, T]. \]

Our dual formulation for \(\mathcal{Y}_0\) is stated in terms of
\[ X_0(l) := \inf_{\lambda \in \Lambda} X_0^{l,\lambda}, \quad l > 0, \]
where
\[ X_0^{l,\lambda} := E \left[ \int_0^T L_s^\lambda \tilde{g}(s, \lambda_s) \, ds + L_T^\lambda \tilde{\Phi}(l/L_T^\lambda) \right], \quad \lambda \in \Lambda, \quad l > 0. \]

The fact that the Fenchel transform of \(X_0\) provides a lower bound for \(\mathcal{Y}_0\) is straightforward, and detailed in Proposition 3.4 below for the convenience of the reader. For ease of notations, we now write \(A_m\) for \(A_{0,m}\), \(M^{0,\alpha}\) for \(M^{(0,0),\alpha}\), and denote by \((Y^{m,\alpha}, Z^{m,\alpha})\) the solution of the BSDE\((g, \Phi(M^{m,\alpha}))\), \(\alpha \in A_m\).

**Proposition 3.4.** \(\mathcal{Y}_0(m) \geq \sup_{l>0} (1m - \mathcal{X}_0(l))\), for all \(m \in [0,1]\).

**Proof.** Fix \(\alpha \in A_m\) and \(\lambda = (\nu, \vartheta) \in \Lambda\). Then, it follows from the definition of \(\tilde{\Phi}\) and \(\tilde{g}\) that
\[ E \left[ Y_T^{m,\alpha} L_T^\lambda \right] = Y_0^{m,\alpha} \]
\[ + E \left[ \int_0^T L_s^\lambda \left( \nu_s Y_s^{m,\alpha} + \vartheta_s^T Z_s^{m,\alpha} - g(s, Y_s^{m,\alpha}, Z_s^{m,\alpha}) \right) \, ds \right] \]
\[ \leq Y_0^{m,\alpha} + E \left[ \int_0^T L_s^\lambda \tilde{g}(s, \lambda_s) \, ds \right], \]
and
\[ Y_T^{m,\alpha} L_T^\lambda = \Phi(M_T^{m,\alpha}) L_T^\lambda \geq l M_T^{m,\alpha} - L_T^\lambda \tilde{\Phi}(l/L_T^\lambda), \]
for \(l > 0\). Note that, in the above, we have cancelled the expectation of the local martingale part \(\int_0^T (L_s^\lambda Z_s^{m,\alpha} + Y_s^{m,\alpha} L_s^\lambda \vartheta_s) \, dW_s\) although \(L^\lambda Z^{m,\alpha}\) might not belong to \(H_2\). If not, one
may use a localization argument since all other terms belongs to $L^1$ uniformly in time. Combining the above and using the martingale property of $M^{m,\alpha}$ yields

$$Y_0^{m,\alpha} \geq im - E \left[ \int_0^T L_s \hat{\Phi}(l/L_T) ds + L_T \hat{\Phi}(l/L_T) \right] = im - X_0^{l,\lambda}.$$ 

The result follows from the arbitrariness of $l > 0$, $\lambda \in \Lambda$, and $\alpha \in \mathcal{A}_m$. \hfill \Box

We now show that equality is satisfied in Proposition 3.4 whenever existence holds in the dual problem. This is proved under the following assumptions. Let $C^1_b$ be the set of continuously differentiable maps with bounded first derivatives.

**Assumption (H^1_d)** The following holds for $\text{Leb} \times \mathbb{P}$-a.e. $(t, \omega) \in [0, T] \times \Omega$:

(a) the maps $\hat{\Phi}(\omega, \cdot)$ and $\hat{g}(\omega, \cdot)$ are $C^1_b$ on their domain, and $\text{dom}(\hat{g}(\omega, t, \cdot))$ is closed;

(b) $|\nabla \hat{\Phi}(\omega, \cdot)| + |\nabla \hat{g}(\omega, t, \cdot)| \leq \chi_{\hat{\Phi}, \hat{g}}^{(\omega)}$, for some $\chi_{\hat{\Phi}, \hat{g}}^{(\omega)} \in L_2(\mathbb{R})$;

(c) $\Phi(\omega, m) = \sup_{l > 0} \left( im - \hat{\Phi}(\omega, l) \right)$, for all $m \in [0, 1]$;

(d) $g(\omega, t, y, z) = \max_{(u,v) \in \text{dom}(\hat{g}(\omega, t, \cdot))} (yu + z^T v - \hat{g}(\omega, t, u, v))$, for all $(y,z) \in \mathbb{R} \times \mathbb{R}^d$.

In the above, $\nabla \hat{\Phi}$ and $\nabla \hat{g}$ stands for the gradient with respect to $l$ and $(u,v)$ respectively.

Note that (a) and (b) are of technical nature, while (c) and (d) mean that $\hat{\Phi}$ and $g$ are convex, i.e. coincide with their bi-dual. The latter is a minimal requirement if one wants the duality to hold.

**Proposition 3.5.** Let Assumption (H^1_d) hold. Assume further that there exists $\hat{l} > 0$ and $\hat{\lambda} \in \Lambda$ such that

$$\sup_{l > 0} (im - \mathcal{X}_0(l)) = \hat{l}m - \mathcal{X}_0(\hat{l}) = \hat{l}m - X_0^{l,\hat{\lambda}}. \tag{3.10}$$

Then, there exists $\hat{\alpha} \in \mathcal{A}_m$ such that

$$\mathcal{X}_0(m) = Y_0^{m,\hat{\alpha}} = \hat{l}m - \mathcal{X}_0(\hat{l}).$$

It satisfies

$$g(\cdot, Y_0^{m,\hat{\alpha}}, Z_0^{m,\hat{\alpha}}) = \hat{\lambda}^T (Y_0^{m,\hat{\alpha}}, Z_0^{m,\hat{\alpha}}) - \hat{g}(\cdot, \hat{\lambda}) \ , \ \Phi(M^{m,\hat{\alpha}}_T) = M^{m,\hat{\alpha},0}_T \hat{\lambda}_T - \hat{\Phi}(\hat{l}/L_T^\lambda). \tag{3.11}$$

Before to provide the proof, let us make the following observation which pertains for the case of a linear driver $g$.

**Remark 3.5.** Assume that $g$ is linear, i.e. there exist bounded predictable processes $A^Y$ and $A^Z$ such that $g : (\omega, t, y, z) \mapsto g(\omega, t, 0, 0) + A^Y(\omega)y + A^Z(\omega)z$. In this case, $\Lambda = \{ (A^Y, A^Z) \}$ and therefore

$$\mathcal{X}_0(l) = E \left[ \int_0^T L_s \hat{g}(s, A^Y_s, A^Z_s) ds + L_T \hat{\Phi}(l/L_T) \right],$$

18
with $L$ given by
\[ L_t = 1 + \int_0^t L_s A_s^Y ds + \int_0^t L_s A_s^Z dW_s, \quad t \in [0, T]. \]

Then, the dual formulation of Proposition 3.5 above drops down to finding $\hat{\lambda}$ which maximizes $lm - \mathcal{X}_0(l)$. This generalizes the result of [6] and [2] obtained for quantile hedging problems in linear models of financial markets.

**Proof of Proposition 3.5.** We split the proof in two steps.

**Step 1.** For ease of notations, we set $\hat{L} := L^{\hat{\lambda}}$. By optimality of $\hat{\lambda}$, one has
\[ \hat{\lambda}_n - E \left[ \hat{L}_T \Phi(\hat{l}/\hat{L}_T) \right] \geq m(\hat{l} + \iota) - E \left[ \hat{L}_T \Phi((\hat{l} + \iota)/\hat{L}_T) \right], \]
for all $\iota > -\hat{\lambda}$. Since $\Phi$ is by construction $\mathbb{P}$-a.s. convex, this implies that $\zeta := \nabla \Phi((\hat{l} + \iota)/\hat{L}_T)$ satisfies $m \iota \leq E[\zeta]$ for all $\iota > -\hat{\lambda}$, recall (3.12), (3.13) and the relation $\nabla \Phi((\hat{l} + \iota)/\hat{L}_T)$ satisfies $m = E[\zeta]$ where $\zeta := \nabla \Phi(\hat{l}/\hat{L}_T)$. (3.12)

We now appeal to (H4) (c) to deduce that
\[ \Phi(\zeta) = (\hat{l}/\hat{L}_T) \geq \Phi(\hat{l}/\hat{L}_T). \] (3.13)

By construction, $\Phi$ is $\mathbb{P}$-a.s. 1-Lipschitz and non-decreasing, i.e. $\zeta \in \mathcal{L}_0([0, 1])$. In view of (3.12), the martingale representation Theorem then implies that we can find $\hat{\alpha} \in \mathcal{A}_m$ such that $\hat{M}_T := M^{\hat{\alpha}_n}_T = \zeta$.

**Step 2.** We now write $(\hat{\nu}, \hat{\theta}) := \lambda$ and fix $\lambda = (\nu, \theta) \in \mathcal{A}$ to be chosen later on. Clearly, $\mathcal{A}$ is convex. Hence, $\lambda^\varepsilon := (1 - \varepsilon)(\hat{\nu}, \hat{\theta}) + \varepsilon(\nu, \theta) \in \mathcal{A}$, $\varepsilon \in [0, 1]$. Moreover, direct computations show that
\[ \frac{\partial}{\partial \varepsilon} \mathcal{L}^\lambda_{\varepsilon} \big|_{\varepsilon=0} = \hat{L}\hat{R} \quad \text{where} \quad \hat{R} := \int_0^T (\hat{\delta}_s - \delta \hat{\nu}_s \hat{\theta}_s) ds + \int_0^T \delta \hat{\nu}_s dW_s, \]
in which we use the notations $\delta \lambda := (\delta \nu, \delta \theta) := (\nu - \hat{\nu}, \theta - \hat{\theta})$.

Recalling that elements of $\mathcal{A}$ take bounded values, see Remark 3.4, and arguing as in Step 1, one easily checks that the optimality condition $X_0^\varepsilon \geq X_0^0$, for all $\varepsilon \in [0, 1]$, implies that $\hat{\eta} := \nabla \hat{g}(:, \lambda)$ satisfies
\[ 0 \leq E \left[ \int_0^T \hat{L}_s \left( \hat{R}_s \hat{g}(s, \hat{\lambda}_s) + \hat{\eta}_s^\top \delta \lambda_s \right) ds + \hat{R}_T \hat{L}_T (\Phi(\hat{l}/\hat{L}_T)) \right] + E \left[ -(\hat{l}/\hat{L}_T) \nabla \Phi(\hat{l}/\hat{L}_T) \right] \]
\[ = E \left[ \int_0^T \hat{L}_s \left( \hat{R}_s \hat{g}(s, \hat{\lambda}_s) + \hat{\eta}_s^\top \delta \lambda_s \right) ds - \hat{R}_T \hat{L}_T \Phi(\hat{M}_T) \right], \quad \text{(3.14)} \]
in which we used (3.12), (3.13) and the relation $\zeta = \hat{M}_T$ to deduce the second equality. Let $(\hat{Y}, \hat{Z})$ be defined by
\[ \hat{Y} := \hat{L}^{-1} E \left[ \hat{L}_T \Phi(\hat{M}_T) - \int_0^T \hat{L}_s \hat{g}(s, \hat{\lambda}_s) ds \right] \quad \text{and} \quad \hat{Z} := \hat{Z} - \hat{Y} \hat{\theta}, \quad \text{(3.15)} \]
Where \( \tilde{Z} \in \mathbb{H}_2 \) is implicitly given by

\[
\tilde{L}_t \tilde{y}_t = \tilde{L}_T \Phi(\tilde{M}_T) - \int_0^T \tilde{L}_s \tilde{g}(s, \tilde{\lambda}_s) ds - \int_0^T \tilde{L}_s \tilde{Z}_s dW_s, \quad 0 \leq t \leq T.
\]  

(3.16)

The above combined with (3.14) implies

\[
0 \leq E \left[ \int_0^T \hat{L}_s \left( \hat{R}_s \hat{g}(s, \hat{\lambda}_s) + \hat{\eta}_s \delta \hat{\lambda}_s \right) ds - \hat{R}_T \hat{L}_T \hat{y}_T \right].
\]

(3.17)

Recalling the definition of \( \hat{R} \) and \( \hat{\eta} \) and applying Itô’s Lemma, this leads to

\[
0 \leq E \left[ \int_0^T \hat{L}_s \left( \hat{\eta}_s - \left( \hat{Y}_s, \hat{Z}_s \right) \right)^\top \delta \hat{\lambda}_s ds \right]
= E \left[ \int_0^T \hat{L}_s \left( \nabla \hat{g}(s, \hat{\lambda}_s) - \left( \hat{Y}_s, \hat{Z}_s \right) \right)^\top \delta \hat{\lambda}_s ds \right].
\]

By Assumption \((H^4)\) (a), Remark 3.4 and [1, Theorem 18.19, p. 605], one can choose \( \hat{\lambda} \in \mathcal{A} \) such that

\[
\hat{\lambda} = \text{argmin}\{ f(\cdot, u, v), (u, v) \in \text{dom}(\tilde{g}(\cdot)) \} \quad \text{Leb} \times \mathbb{P}-\text{a.e.}
\]

where

\[
f : (\omega, s, u, v) \mapsto \left( \nabla \tilde{g}(\omega, s, \hat{\lambda}_s(\omega)) - \left( \hat{Y}_s(\omega), \hat{Z}_s(\omega) \right) \right)^\top (u - \hat{v}_s(\omega), v - \hat{\vartheta}_s(\omega)).
\]

Considering now Relation (3.17) with \( \lambda \) chosen to be equal to \( \hat{\lambda}_1 \{ f(\cdot, \lambda) < 0 \} \), we see that, for \( \text{Leb} \times \mathbb{P}-\text{a.e.} \ (\omega, t) \in \Omega \times [0, T] \), the gradient \( \Delta_t(\omega) \) of \( \hat{\lambda}_t(\omega) \) of the convex map

\[
(u, v) \in \text{dom}(\tilde{g}(\omega, t, \cdot)) \mapsto F(\omega, t, u, v) := \tilde{g}(\omega, t, u, v) - u \hat{Y}_t(\omega) - v^\top \hat{Z}_t(\omega)
\]

satisfies

\[
\Delta_t(\omega)^\top (b - \hat{\lambda}_t(\omega)) \geq 0, \quad \text{for all } b \in \text{dom}(\tilde{g}(\omega, t, \cdot)).
\]

This implies that \( \hat{\lambda}_t(\omega) \) minimizes \( F(\omega, t, \cdot) \) for \( \text{Leb} \times \mathbb{P}-\text{a.e.} \ (\omega, t) \in \Omega \times [0, T] \) and therefore we compute

\[
\tilde{g}(\cdot, \hat{\lambda}) = \hat{\lambda}^\top (\hat{Y}, \hat{Z}) - g(\cdot, \hat{Y}, \hat{Z}) \quad \text{Leb} \times \mathbb{P}-\text{a.e.}
\]

by \((H^4)\) (d). Combining the above identity with (3.16) leads to \( (\hat{Y}, \hat{Z}) = (Y^{m, \hat{\alpha}}, Z^{m, \hat{\alpha}}) \).

Then, by using (3.12), (3.13) and (3.15), in which \( \hat{L}_0 = 1 \), we obtain

\[
Y_0^{m, \hat{\alpha}} = E \left[ \hat{L}_T \Phi(\hat{M}_T) - \int_0^T \hat{L}_s \tilde{g}(s, \hat{\lambda}_s) ds \right]
= E \left[ \hat{L}_T \left( \hat{\iota}/\hat{L}_T - \hat{\Phi}(\hat{\iota}/\hat{L}_T) \right) - \int_0^T \hat{L}_s \tilde{g}(s, \hat{\lambda}_s) ds \right]
= \hat{l}m - E \left[ \hat{L}_T \hat{\Phi}(\hat{\iota}/\hat{L}_T) + \int_0^T \hat{L}_s \tilde{g}(s, \hat{\lambda}_s) ds \right].
\]

In view of Proposition 3.4, this concludes the proof. \( \square \)

We now state the reciprocal statement: existence in the primal problem provides existence in the dual one. Here again, we need to impose some additional technical conditions.

**Assumption \((H^2)\)** The following holds for \( \text{Leb} \times \mathbb{P}-\text{a.e.} \ (t, \omega) \in [0, T] \times \Omega:

20
(a) the maps $\Phi(\omega, \cdot)$ and $g(\omega, t, \cdot)$ are $C^1_b$ on $[0, 1]$ and $\mathbb{R} \times \mathbb{R}^d$ respectively;

(b) $|\nabla \Phi(\omega, \cdot)| \leq \chi_\Phi(\omega)$, for some $\chi_\Phi \in L_2(\mathbb{R})$.

**Proposition 3.6.** Let Assumption (H^3_d) hold. Let $l > 0$ be fixed and assume that there exists $\tilde{m} \in [0, 1]$ and $\tilde{\alpha} \in A_{\tilde{m}}$ such that

$$
\sup_{m \in [0, 1]} \sup_{\alpha \in A_m} (ml - Y_0(m)) = \tilde{m}l - Y_0^{\tilde{m}, \tilde{\alpha}}.
$$

Then, there exists $\tilde{\lambda} \in \Lambda$ such that

$$
Y_0(\tilde{m}) = \tilde{m}l - \lambda_0 = \tilde{m}l - X_0^{\tilde{m}, \tilde{\alpha}}
$$

and $\tilde{\lambda}$ satisfies (3.11) with $m = \tilde{m}$ and $l = l$.

**Proof.** Given $\varepsilon \in [0, 1]$, a martingale $M$ with values in $[0, 1]$, $m := M_0$, we set $m_\varepsilon := \tilde{m} + \varepsilon (m - \tilde{m})$, $M^\varepsilon := M + \varepsilon (M - \tilde{M})$, where $\tilde{M} := M^{\tilde{m}, \tilde{\alpha}}$. For ease of notation, we set $(\tilde{Y}, \tilde{Z}) := (Y^{\tilde{m}, \tilde{\alpha}}, Z^{\tilde{m}, \tilde{\alpha}})$ and denote by $(Y^\varepsilon, Z^\varepsilon)$ the solution of BSDE($g, \Phi(M^\varepsilon)$), $\delta m := m - \tilde{m}$, $(\delta M, \delta Y^{\varepsilon}, \delta Z^{\varepsilon}) := (M - \tilde{M}, Y^{\varepsilon} - \tilde{Y}, Z^{\varepsilon} - \tilde{Z})$.

**Step 1.** We first show that $\varepsilon^{-1}(\delta Y^\varepsilon, \delta Z^\varepsilon)$ converges in $S_2 \times H_2$ as $\varepsilon \to 0$ to the solution $(\nabla Y, \nabla Z)$ of

$$
\nabla Y_t = \nabla \Phi(\tilde{M}) \delta M_T + \int_t^T \nabla g(s, \tilde{Y}_s, \tilde{Z}_s) \nabla (\nabla Y_s, \nabla Z_s) ds - \int_t^T \nabla Z_s dW_s.
$$

First note that existence and uniqueness of the solution to the above BSDE is guaranteed by Assumption (H^3_d).

Letting $\xi^\varepsilon := \varepsilon^{-1}(\Phi(M^\varepsilon) - \Phi(\tilde{M}))$, one easily checks that $\varepsilon^{-1}(\delta Y^\varepsilon, \delta Z^\varepsilon)$ solves

$$
\frac{\delta Y^\varepsilon}{\varepsilon} = \xi^\varepsilon - \int_s^T \frac{\delta Z^\varepsilon}{\varepsilon} dW_r + \int_s^T \left( A^Y_r \frac{\delta Y^\varepsilon}{\varepsilon} + A^Z_r \frac{\delta Z^\varepsilon}{\varepsilon} \right) dr,
$$

where

$$
A^Y_r := \int_0^1 \partial_y g(r, \theta \tilde{Y}_r, \theta \tilde{Z}_r) d\theta \quad \text{and} \quad A^Z_r := \int_0^1 \partial_z g(r, \theta \tilde{Y}_r, \theta \tilde{Z}_r) d\theta.
$$

In the above, $\partial_y g$ and $\partial_z g$ denotes respectively the partial gradients of $g$ with respect to $y$ and $z$, recall (H^3_d). The Assumption (H_g) implies $|A^Y^\varepsilon| + |A^Z^\varepsilon| \leq K_g$.

We now set $U^\varepsilon := \varepsilon^{-1} \delta Y^\varepsilon - \nabla Y$, $V^\varepsilon := \varepsilon^{-1} \delta Z^\varepsilon - \nabla Z$ and $\zeta^\varepsilon := \xi^\varepsilon - \nabla \Phi(\tilde{M}) \delta M$. The pair $(U^\varepsilon, V^\varepsilon)$ is an element of $S_2 \times H_2$ and solves

$$
U^\varepsilon_s = \zeta^\varepsilon - \int_s^T V^\varepsilon_r dW_r + \int_s^T \left( A^Y_r U^\varepsilon_r + A^Z_r V^\varepsilon_r + R^\varepsilon_r \right) dr, \quad 0 \leq s \leq T,
$$

with

$$
R^\varepsilon_r := \nabla Z_r (A^Z_r - \partial_z g(r, \tilde{Y}_r, \tilde{Z}_r)) + \nabla Y_r (A^Y_r - \partial_y g(r, \tilde{Y}_r, \tilde{Z}_r)), \quad 0 \leq r \leq T.
$$
Hence, by stability for Lipschitz BSDEs (see Proposition 5.1 in the Appendix) there exists a constant $C > 0$ (which does not depend on $\varepsilon$) such that

$$
\|U^\varepsilon\|_{S_2}^2 + \|V^\varepsilon\|_{H^2_2}^2 \leq C \left( \|\xi^\varepsilon\|_{L_2}^2 + \|R^\varepsilon\|_{H^2_2}^2 \right).
$$

(3.20)

The result of Step 1. will follow if we prove that the right-hand side of the inequality (3.20) vanishes as $\varepsilon$ tends to zero. The convergence of $\|R^\varepsilon\|_{H^2_2}$ to 0 follows from Assumption $(H^2_2)$ and the convergence of $M^\varepsilon_T$ to $M_T$. As for the second term, it suffices to prove that $(Y^\varepsilon, Z^\varepsilon)_\varepsilon$ converges in $S_2 \times H_2$ to $(\hat{Y}, \hat{Z})$, and to appeal to $(H_g)$ and $(H^3_3)$. The latter is obtained by standard stability results, see Proposition 5.1 below, which imply the existence of a constant $C > 0$ (which does not depend on $\varepsilon$) such that

$$
\|Y^\varepsilon - \hat{Y}\|_{S_2}^2 + \|Z^\varepsilon - \hat{Z}\|_{H_2}^2 \leq C \|\Phi(M^\varepsilon_T) - \Phi(\hat{M}_T)\|_{L_2}^2 \to \varepsilon \to 0.
$$

In the latter, the convergence follows from Lebesgue’s dominated convergence Theorem and assumption $(H^3_3)$.

**Step 2.** By optimality of $(\hat{m}, \hat{\alpha})$, $Y^\varepsilon_0 - m_{\hat{\alpha}}l - \hat{Y}_0 + \hat{m}l \geq 0$, for any $\varepsilon > 0$. In view of Step 1, dividing by $\varepsilon > 0$ and sending $\varepsilon \to 0$ leads to

$$
0 \leq \nabla \Phi(\hat{M}_T)\delta M_T - l\delta m + \int_0^T \nabla g(s, \hat{Y}_s, \hat{Z}_s)^\top (\nabla Y_s, \nabla Z_s) ds - \int_0^T \nabla Z_s dW_s
$$

$$
= \nabla Y_0 - l\delta m,
$$

after possibly passing to a subsequence.

Set $\tilde{L} := L^\lambda$ where $\lambda := \nabla g(\cdot, \hat{Y}, \hat{Z})$. Observe that the latter belongs to $\Lambda$. For later use, also notice that

$$
g(\cdot, \hat{Y}, \hat{Z}) = (\hat{\nu}, \hat{\vartheta})^\top (\hat{Y}, \hat{Z}) - \hat{g}(\cdot, \hat{\nu}, \hat{\vartheta}),
$$

(3.21)

see e.g. [13]. Then, it follows from (3.19) that $\tilde{L}\nabla Y$ is a martingale. The previous inequality thus implies that

$$
0 \leq \tilde{L}_0 \nabla Y_0 - l\delta m = E \left[ \tilde{L}_T \nabla Y_T \right] - l\delta m = E \left[ \tilde{L}_T \delta M_T \left( \nabla \Phi(\hat{M}_T) - l/\tilde{L}_T \right) \right],
$$

in which we used the fact that $\tilde{L}_0 = 1$ and $E[\delta M_T] = \delta m$. Since $M_T$ can be any arbitrary random variable with values in $[0, 1]$, this shows that, $\mathbb{P}$ a.s., $M_T(\omega)$ minimizes $m \in [0, 1] \mapsto \Phi(\omega, m) - ml/\tilde{L}_T(\omega)$. Hence,

$$
\tilde{M}_T l - \tilde{L}_T \Phi(\tilde{M}_T) = \tilde{L}_T \Phi(l/\tilde{L}_T),
$$

see e.g. [13]. Combining the above identity together with (3.21) and using Itô’s Lemma leads to $l\hat{m} - \hat{Y}_0 = X^T_{\hat{\alpha}}$. One concludes by appealing to Proposition 3.4. \qed

### 4 Proof of Theorem 2.1

In all this section, we use the notations introduced at the beginning of Section 2.2. The first main result provides a dynamic programming principle for the family $\{Y^\alpha_T, \tau \in T, \alpha \in A_0\}$.  

Proposition 4.1. For all \((\tau_1, \tau_2, \alpha) \in \mathcal{T} \times \mathcal{T} \times A_0\) such that \(\tau_1 \leq \tau_2\), we have

\[
\mathcal{Y}_{\tau_1}^{\alpha} = \operatorname{ess} \inf_{\alpha' \in A_{\tau_1}} \mathcal{E}_{\tau_1, \tau_2}^{\alpha'} [\mathcal{Y}_{\tau_2}^{\alpha'}] .
\]

Proof. We prove the two corresponding inequalities separately.

Step 1. \(\mathcal{Y}_{\tau_1}^{\alpha} \geq \operatorname{ess} \inf_{\alpha' \in A_{\tau_1}} \mathcal{E}_{\tau_1, \tau_2}^{\alpha'} [\mathcal{Y}_{\tau_2}^{\alpha'}]\).

It follows from Lemma 4.1 below that there exists \((\alpha^n)_n\) in \(A_{\tau_1}^n\) such that the sequence \((\mathcal{E}_{\tau_1, \tau_2}^{\alpha^n} [\Phi(M_T^n)])_n\) is non-increasing and

\[
\lim_{n \to \infty} \mathcal{E}_{\tau_1, \tau_2}^{\alpha^n} [\Phi(M_T^n)] = \mathcal{Y}_{\tau_1}^{\alpha} , \quad \mathbb{P} - \text{a.s.} \quad (4.1)
\]

Since \(\alpha^n \in A_{\tau_2}^\alpha\) for every \(n \geq 1\), we deduce that

\[
\mathcal{Y}_{\tau_2}^{\alpha^n} \leq \mathcal{E}_{\tau_2, \tau_2}^{\alpha^n} [\Phi(M_T^n)] .
\]

By comparison for BSDEs with Lipschitz continuous drivers on the time interval \([\tau_1, \tau_2]\), this implies

\[
\mathcal{E}_{\tau_1, \tau_2}^{\alpha^n} [\mathcal{Y}_{\tau_2}^{\alpha^n}] \leq \mathcal{E}_{\tau_1, \tau_2}^{\alpha^n} [\mathcal{E}_{\tau_1, \tau_2}^{\alpha^n} [\Phi(M_T^n)]] = \mathcal{E}_{\tau_1, \tau_2}^{\alpha^n} [\Phi(M_T^n)] ,
\]

leading to

\[
\operatorname{ess} \inf_{\alpha' \in A_{\tau_1}} \mathcal{E}_{\tau_1, \tau_2}^{\alpha'} [\mathcal{Y}_{\tau_2}^{\alpha'}] \leq \mathcal{E}_{\tau_1, \tau_2}^{\alpha^n} [\mathcal{Y}_{\tau_2}^{\alpha^n}] ,
\]

Letting \(n\) go to infinity in the above inequality, (4.1) provides directly

\[
\operatorname{ess} \inf_{\alpha' \in A_{\tau_1}} \mathcal{E}_{\tau_1, \tau_2}^{\alpha'} [\mathcal{Y}_{\tau_2}^{\alpha'}] \leq \mathcal{Y}_{\tau_1}^{\alpha} .
\]

Step 2. \(\mathcal{Y}_{\tau_1}^{\alpha} \leq \operatorname{ess} \inf_{\alpha' \in A_{\tau_1}} \mathcal{E}_{\tau_1, \tau_2}^{\alpha'} [\mathcal{Y}_{\tau_2}^{\alpha'}]\).

Fix \(\alpha'\) in \(A_{\tau_1}^\alpha\). Lemma 4.1 below ensures the existence of a sequence \((\alpha'_n)_n\) in \(A_{\tau_2}^\alpha\) such that \((\mathcal{E}_{\tau_2, \tau_2}^{\alpha'_n} [\Phi(M_T^{\alpha'_n})])_n\) is non-increasing and

\[
\lim_{n \to \infty} \mathcal{E}_{\tau_2, \tau_2}^{\alpha'_n} [\Phi(M_T^{\alpha'_n})] = \mathcal{Y}_{\tau_2}^{\alpha'} , \quad \mathbb{P} - \text{a.s.}
\]

In view of Remark 2.1, the convergence holds in \(L_2\) as well. Thus the stability result of Proposition 5.1 below indicates that \(\mathcal{E}_{\tau_2, \tau_2}^{\alpha'_n} [\Phi(M_T^{\alpha'_n})]\) converges to \(\mathcal{E}_{\tau_1, \tau_2}^{\alpha} [\mathcal{Y}_{\tau_2}^{\alpha'}]\) in \(L_2\). In addition, \(\alpha'_n \in A_{\tau_2}^\alpha \subset A_{\tau_1}^\alpha\) by construction. Combining the above leads to

\[
\mathcal{E}_{\tau_1, \tau_2}^{\alpha} [\mathcal{Y}_{\tau_2}^{\alpha'}] = \lim_{n \to \infty} \mathcal{E}_{\tau_1, \tau_2}^{\alpha'_n} [\Phi(M_T^{\alpha'_n})] \geq \mathcal{Y}_{\tau_1}^{\alpha} .
\]

The arbitrariness of \(\alpha' \in A_{\tau_1}^\alpha\) allows one to conclude

\[
\operatorname{ess} \inf_{\alpha' \in A_{\tau_1}^\alpha} \mathcal{E}_{\tau_1, \tau_2}^{\alpha'} [\mathcal{Y}_{\tau_2}^{\alpha'}] \geq \mathcal{Y}_{\tau_1}^{\alpha} .
\]

\[\square\]
Lemma 4.1. Fix $\theta, \tau \in T$, with $\theta \geq \tau$, $\mu \in L_0([0,1],F_\tau)$ and $\alpha \in A_{\tau,\mu}$. Then, there exists a sequence $(\alpha'_n) \subset A^0_{\tau,\mu} := \{ \alpha \in A_{\tau,\mu}, \alpha'_1(0,\theta) = \alpha 1_{(0,\theta)} \}$ such that $\lim_n \inf_{\theta \in (0,\theta]} \mathcal{E}_{\theta,T}^g[\Phi(M^{\tau,\mu}_T)] = \mathcal{Y}_\theta^\alpha(M^{\tau,\mu}_{T\theta}) \mathbb{P} - \text{a.s.}$

Proof. It suffices to show that the family $\{ J(\alpha') := \mathcal{E}_{\theta,T}^g[\Phi(M^{\tau,\mu}_T)] : \alpha' \in A^0_{\tau,\mu} \}$ is directed downward, see e.g. [9]. Fix $\alpha'_{1}, \alpha'_{2}$ in $A^0_{\tau,\mu}$ and set

$$\tilde{\alpha}' := \alpha 1_{(0,\theta)} + 1_{[\theta,T]}(\alpha'_1 A + \alpha'_2 A^c)$$

where $A := \{ J(\alpha'_1) \leq J(\alpha'_2) \} \in F_\theta$, so that $\tilde{\alpha}' \in A^0_{\tau,\mu}$ and

$$J(\tilde{\alpha}') = \mathcal{E}_{\theta,T}^g[\Phi(M^{\tau,\mu}_T)A + \Phi(M^{\tau,\mu}_T)A^c] = \min\{J(\alpha'_1), J(\alpha'_2)\}.$$

We now observe that the family $(\mathcal{Y}^\alpha)_{\alpha \in H_2}$ is lãõlâ on countable sets. If in addition $\Phi$ is assumed to be continuous, the process $(\mathcal{Y}^\alpha)_{\alpha \in H_2}$ is even indistinguishable from a càdlâg process.

Proposition 4.2. Fix $\alpha \in A_0$. Then, $\mathcal{Y}^\alpha$ is lãõlâ on countable sets. Besides, if $m \in [0,1] \mapsto \Phi(\omega, m)$ is continuous for $\mathbb{P}$-a.e. $\omega \in \Omega$, then $\mathcal{Y}^\alpha$ is indistinguishable from a càdlâg process.

Proof. Fix $\alpha \in A_0$. Proposition 4.1 and Remark 2.1 imply that $-\mathcal{Y}^\alpha$ is a $-g(-)$-supermartingale in the sense of [3] (a $g$-submartingale in the sense of [11]). It follows from the non-linear up-crossing Lemma, see [3, Theorem 6]4, that the following limits

$$\lim_{s \in D \cap (t,T) \setminus \mu} \mathcal{Y}^\alpha_s \quad \text{and} \quad \lim_{s \in D \cap [0,t] \setminus t} \mathcal{Y}^\alpha_s$$

are well-defined for every $t \in [0,T]$, $\mathbb{P}$ - a.s., and for all countable set $D$. So is the process

$$\tilde{\mathcal{Y}}^\alpha_t := \lim_{s \in \mathbb{Q} \cap (t,T) \setminus \mu} \mathcal{Y}^\alpha_s, \quad t \in [0,T].$$

Besides, $\tilde{\mathcal{Y}}^\alpha$ is by definition càd. Assuming that $\Phi$ is continuous, we will prove that, for every stopping time $\tau$, it holds that:

$$\tilde{\mathcal{Y}}^\alpha_\tau = \text{ess inf}_{\alpha' \in A^0_\tau} \mathcal{E}_{\tau,T}^g[\Phi(M^{\tau,\mu}_T)] (= \mathcal{Y}^\alpha_\tau) \quad \mathbb{P} - \text{a.s.} \quad (4.2)$$

By [4, Chapter IV, (86), p. 220], the relation (4.2) entails that $\mathcal{Y}^\alpha$ and $\tilde{\mathcal{Y}}^\alpha$ are undistinguishable showing that $\mathcal{Y}^\alpha$ is undistinguishable from a càdlâg process. The rest of the proof is devoted to (4.2).

4Note that [3, Theorem 6] restricts to positive $g$-supermartingales. However, the proof can be reproduced without difficulty under the integrability condition of Remark 2.1. In addition, [3, Theorem 6] implies that $E^\mathbb{Q}[D^e_b(\mathcal{Y}^\alpha, n)] \leq \mathcal{Y}^\alpha_\infty \wedge b \leq b$, where $D^e_b(\mathcal{Y}^\alpha, n)$ denotes the number of down crossing of $\mathcal{Y}^\alpha$ from an interval $[a,b]$ on a discrete time-grid $0 = t_0 \leq t_1 \leq \cdots \leq t_n = T$ and $\mathbb{Q}$ is a particular measure absolutely continuous with respect to $\mathbb{P}$. To conclude, it is enough to reproduce the proof of [4, Chapter VI Theorem (2) point 1].
For this purpose, let us introduce \((\tau_n)_n\), a decreasing sequence of stopping times with values in \([0,T] \cap \mathbb{Q}\) such that \(\tau \leq \tau_n \leq \tau + n^{-1}\) and \(\bar{Y}_\tau^\alpha = \lim_{n \to \infty} Y_{\tau_n}^\alpha\).

**Step 1.** \(\bar{Y}_\tau^\alpha \leq \text{ess inf}_{\alpha' \in A_2} \mathcal{E}_{\tau,T}^g \{ \Phi(M_T^{\alpha'}) \} \).

**a.** Fix \(\alpha' \in A_2^\alpha\) and set

\[
\lambda_n := \left( \frac{M_{\tau_n}^{\alpha'}}{M_{\tau_n}^{\alpha'}} - \frac{1}{1 - M_{\tau_n}^{\alpha'}} \right) 1_{\{M_{\tau_n}^{\alpha'} \notin \{0,1\}\}} \in [0,1],
\]

with the convention \(a/b = \infty\) for \(a > 0\). Using the fact that \(M_{\tau_n}^{\alpha'} + \int_{\tau_n}^T \alpha'_s dW_s = M_T^{\alpha'} \in [0,1]\), direct computations lead to

\[
0 \leq M_{\tau_n}^{\alpha} - \lambda_n M_{\tau_n}^{\alpha'} \leq M_{\tau_n}^{\alpha} + \lambda_n \int_{\tau_n}^T \alpha'_s dW_s \leq M_{\tau_n}^{\alpha} + \lambda_n(1 - M_{\tau_n}^{\alpha'}) \leq 1.
\]

We set \(\alpha'_n := \alpha 1_{[0,\tau_n]} + \lambda_n \alpha' 1_{[\tau_n,T]}\). The above implies that \(\alpha'_n\) belongs to \(A_{\tau_n}^\alpha\).

**b.** Now we prove that \(M_T^{\alpha'}\) converges \(M_T^{\alpha}\) in \(L_2\) as \(n\) goes to infinity, possibly up to a subsequence. Since both have norms bounded by 1, it suffices to show the \(\mathbb{P}\) – a.s. convergence, possibly up to a subsequence. To see this, first note that

\[
M_T^{\alpha'} - M_T^{\alpha''} = M_{\tau_n}^{\alpha} - M_{\tau_n}^{\alpha'} + \int_{\tau_n}^T (\lambda_n - 1)\alpha'_s dW_s,
\]

from which we deduce that

\[
M_T^{\alpha''} - M_T^{\alpha'} = M_{\tau_n}^{\alpha} - M_{\tau_n}^{\alpha'} + (\lambda_n - 1) 1_{\{M_{\tau_n}^{\alpha'} \notin \{0,1\}\}} \int_{\tau_n}^T \alpha'_s dW_s
\]

\[- 1_{\{M_{\tau_n}^{\alpha} \notin \{0,1\}\}} \int_{\tau_n}^T \alpha'_s dW_s.
\]

Since \(\tau_n \to \tau\ \mathbb{P}\)-a.s. and \(\alpha'' = \alpha\) on \([0,\tau]\), the above construction implies that \(\lim_{n \to \infty} M_{\tau_n}^{\alpha} - M_{\tau_n}^{\alpha'} = 0\ \mathbb{P}\)-a.s. and \(\lim_{n \to \infty} \lambda_n = \lim_{n \to \infty} 1_{\{M_{\tau_n}^{\alpha'} \notin \{0,1\}\}} \mathbb{P}\)-a.s. It thus only remains to prove that \(1_{\{M_{\tau_n}^{\alpha} \notin \{0,1\}\}} \int_{\tau_n}^T \alpha'_s dW_s \to 0\ \mathbb{P}\)-a.s. First note that \(\alpha' 1_{[\tau_n,T]} = 0\) on \(\{M_{\tau_n}^{\alpha'} \in \{0,1\}\}\). This follows from the martingale property of this process with values in \([0,1]\). Hence, it suffices to consider \(1_{\{M_{\tau_n}^{\alpha'} \neq M_{\tau_n}^{\alpha} \in \{0,1\}\}} \int_{\tau_n}^T \alpha'_s dW_s\). But, since \(M_T^{\alpha'} = M_T^{\alpha}\),

\[
\mathbb{P}[M_{\tau_n}^{\alpha'} \neq M_{\tau_n}^{\alpha} \in \{0,1\}] \leq \mathbb{P}[M_{\tau_n}^{\alpha'} \neq M_{\tau_n}^{\alpha}] = \mathbb{P} \left[ \left| \int_{\tau}^{\tau_n} (\alpha_s - \alpha'_s) dW_s \right| > 0 \right] \to_{n \to \infty} 0.
\]

**c.** Now, since \(\Phi\) is continuous and \(M_T^{\alpha'} \in L_0([0,1])\), we get that \(\Phi(M_T^{\alpha'}) \to \Phi(M_T^{\alpha'})\) in \(L_2\), after possibly passing to a subsequence. The stability property for Lipschitz BSDEs given in Proposition 5.1 implies that

\[
\left\| \mathcal{E}_{\tau,T}^g \left[ \Phi(M_T^{\alpha''}) \right] - \mathcal{E}_{\tau,T}^g \left[ \Phi(M_T^{\alpha'}) \right] \right\|_{L_2} \to_{n \to \infty} 0. \tag{4.3}
\]

On the other hand, the bound of Remark 2.1 implies that

\[
\left\| \mathcal{E}_{\tau,T}^g \left[ \Phi(M_T^{\alpha''}) \right] - \mathcal{E}_{\tau,T}^g \left[ \Phi(M_T^{\alpha'}) \right] \right\|_{L_2} \to_{n \to \infty} 0, \tag{4.4}
\]
by Lebesgue’s dominated convergence Theorem and by continuity of the process $E^\alpha_{\tau,T} \left[ \Phi(M^n_T) \right]$. Combining (4.3) and (4.4) leads to

$$
\mathcal{Y}_\tau^\alpha = \lim_{n \to \infty} \mathcal{Y}_\tau^\alpha_n \leq \lim_{n \to \infty} E^\alpha_{\tau,n,T} \left[ \Phi(M^n_T) \right] = E^\alpha_{\tau,T} \left[ \Phi(M_T^\alpha) \right].
$$

We conclude by arbitrariness of $\alpha' \in A^\alpha_T$.

**Step 2.** $\mathcal{Y}_\tau^\alpha \geq \text{ess inf}_{\alpha' \in A^\alpha_T} E^\alpha_{\tau,T} \left[ \Phi(M_T^{\alpha'}) \right]$.

Applying on $[\tau, \tau^n]$ the stability result of Proposition 5.1 for the BSDEs with parameters $(\mathcal{Y}_\tau^\alpha, 0)$ and $(\mathcal{Y}_\tau^\alpha, g1_{[0, \tau^n)})$, we get

$$
\| \mathcal{Y}_\tau^\alpha - E^\alpha_{\tau,\tau^n} [\mathcal{Y}_\tau^{\alpha^n}] \|_{L^2} \leq C \left( \| \mathcal{Y}_\tau^\alpha - \mathcal{Y}_\tau^{\alpha^n} \|_{L^2} + E \left[ \int_\tau^{\tau^n} |g(s, \mathcal{Y}_\tau^\alpha, 0)|^2 \, ds \right] \right)
$$

$$
\leq C \| \mathcal{Y}_\tau^\alpha - \mathcal{Y}_\tau^{\alpha^n} \|_{L^2} + \frac{C}{n}, \quad n \in \mathbb{N},
$$

for some $C > 0$, since the bound of Remark 2.1 holds for $\mathcal{Y}_\tau^\alpha$, recall that Assumption $(H_0)$ is in force. Therefore, $E^\alpha_{\tau,\tau^n} [\mathcal{Y}_\tau^{\alpha^n}]$ converges to $\mathcal{Y}_\tau^\alpha$ as $n$ goes to infinity. Proposition 4.1 implies $E^\alpha_{\tau,\tau^n} [\mathcal{Y}_\tau^{\alpha^n}] \geq \mathcal{Y}_\tau^\alpha$. Passing to the limit leads to the required inequality: $\mathcal{Y}_\tau^\alpha \geq \mathcal{Y}_\tau^\alpha = \text{ess inf}_{\alpha' \in A^\alpha_T} E^\alpha_{\tau,T} \left[ \Phi(M_T^{\alpha'}) \right]$. \hfill $\Box$

In the rest of this section, we complete the proof of Theorem 2.1.

**Proof of Theorem 2.1.** Items (i) and (ii) are already proved in Proposition 4.1 and Proposition 4.2, it remains to prove (iii) and (iv). For $\alpha \in A_0$, it follows from Proposition 4.1, Proposition 4.2 and standard comparison results for BSDEs that $\mathcal{Y}^\alpha$ is a càdlàg strong $g$-submartingale in the sense of [11]. Hence, the existence of a process $(\mathcal{Z}^\alpha, K^\alpha) \in H_2 \times K_2$ such that (2.9) holds follows from [11, Theorem 3.3]. We now verify successively that the family $(\mathcal{Y}^\alpha, \mathcal{Z}^\alpha, K^\alpha)_{\alpha \in H_2}$ satisfies (2.8), (2.10), (2.11) and the uniqueness of solution for (2.8)-(2.9)-(2.10)-(2.11).

The bound (2.8) follows directly from Remark 2.1 and the representation Theorem 3.3 in [11], note that the driver function $g$ does not depend on $\alpha \in A_0$.

**Step 1. The irrelevance of future property (2.11)**

For $(\alpha, \tau) \in A_0 \times T$, observe that $A^\alpha \times [0, \tau]$ when $\alpha' \in A_0^\tau$. The definition of $\mathcal{Y}$ thus implies that $\mathcal{Y}^\alpha = \mathcal{Y}^\alpha \mathcal{1}_{[0, \tau]} = \mathcal{Y}^\alpha \mathcal{1}_{[0, \tau]}$ for $\alpha' \in \mathcal{A}^\alpha_{\tau_1}$. Hence (2.11) follows from the uniqueness of the representation provided in [11, Theorem 3.3].

**Step 2. The minimality property (2.10)**

We follow the arguments in the proof [16, Theorem 4.6]. We fix $(\alpha, \tau_1, \tau_2) \in H_2 \times T \times T$ such that $\tau_1 \leq \tau_2$. For any $\alpha' \in A_{\tau_1}$, we denote by $(\mathcal{Y}^{\alpha'}, Z^{\alpha'})$ the solution of the classical BSDE

$$
\mathcal{Y}^{\alpha'}_t = \Phi(M^{\alpha'}_T) + \int_t^T g(s, \mathcal{Y}^{\alpha'}_s, Z^{\alpha'}_s) \, ds - \int_t^T Z^{\alpha'}_s \, dW_s, \quad 0 \leq t \leq T.
$$

26
Let $L^{\alpha'}$ be the process whose dynamics is given by

$$L_t^{\alpha'} = \exp \left( \int_{\tau_1}^t \Lambda_s^z dW_s + \int_{\tau_1}^t \left( \Lambda_s^y - \frac{|\Lambda_s^y|^2}{2} \right) ds \right) , \quad \tau_1 \leq t \leq T ,$$

where $(\Lambda^y, \Lambda^z)$ is the linearization process given by

$$\Lambda^y := \frac{g(Y_\alpha, Z_\alpha) - g(Y_{\alpha'}^y, Z_{\alpha'}^y)}{Y_\alpha - Y_{\alpha'}^y} \mathbf{1}_{\{Y_{\alpha'}^y \neq Y_\alpha\}} ,$$

$$\Lambda^z := \frac{g(Y_\alpha, Z_\alpha) - g(Y_{\alpha'}^z, Z_{\alpha'}^z)}{|Z_\alpha - Z_{\alpha'}^y|^2} (Z_\alpha - Z_{\alpha'}^y) \mathbf{1}_{\{Z_{\alpha'}^y \neq Z_\alpha\}} .$$

This linearization procedure implies that $Y_{\tau_1}^{\alpha'} - Y_{\tau_1}^\alpha$ rewrites as

$$Y_{\tau_1}^{\alpha'} - Y_{\tau_1}^\alpha = E_{\tau_1} \left[ L_{\tau_2}^{\alpha'} (Y_{\tau_2}^{\alpha'} - Y_{\tau_2}^\alpha) \right] + E_{\tau_1} \left[ \int_{\tau_1}^{\tau_2} L_s^{\alpha'} dK_s^{\alpha'} \right] \geq E_{\tau_1} \left[ (K_{\tau_2}^{\alpha'} - K_{\tau_1}^{\alpha'}) \inf_{[\tau_1, \tau_2]} L_s^{\alpha'} \right] ,$$

where we used the fact that $Y_\alpha - Y_{\alpha'} \geq 0$. Using Hölder inequality, this implies

$$E_{\tau_1} \left[ (K_{\tau_2}^{\alpha'} - K_{\tau_1}^{\alpha'})^3 \right] \leq E_{\tau_1} \left[ (K_{\tau_2}^{\alpha'} - K_{\tau_1}^{\alpha'}) \inf_{[\tau_1, \tau_2]} L_s^{\alpha'} \right] E_{\tau_1} \left[ \sup_{[\tau_1, \tau_2]} (1/L_s^{\alpha'}) \right] E_{\tau_1} \left[ (K_{\tau_2}^{\alpha'} - K_{\tau_1}^{\alpha'})^2 \right] \leq C E_{\tau_1} \left[ (K_{\tau_2}^{\alpha'} - K_{\tau_1}^{\alpha'})^2 \right] (Y_{\tau_1}^{\alpha'} - Y_{\tau_1}^\alpha) ,$$

for some $C > 0$ that depends on the uniform bounds on $(\Lambda^y, \Lambda^z)$, recall $(H_y)$. Hence, the estimate (2.8) together with the monotonicity of $K$ implies

$$0 \leq E_{\tau_1} \left[ (K_{\tau_2}^{\alpha'} - K_{\tau_1}^{\alpha'}) \right] \leq C \eta_{\tau_1}^{\alpha'} (Y_{\tau_1}^{\alpha'} - Y_{\tau_1}^\alpha)^{1/3} , \quad \alpha' \in A_{\tau_1}^\gamma ,$$

where

$$\eta_{\tau_1}^{\alpha'} := \text{ess sup} \sum_{\alpha \in A_{\tau_1}^\gamma} E_{\tau_1} \left[ (K_{\tau_2}^{\alpha} - K_{\tau_1}^{\alpha})^2 \right]^{1/3} .$$

By the same arguments as in Lemma 4.1, we can find a sequence $(\alpha_n')_n \subset A_{\tau_1}^\gamma$ such that

$$\eta_{\tau_1}^{\alpha_n'} = \lim_{n \to \infty} \sup_{\alpha \in A_{\tau_1}^\gamma} E_{\tau_1} \left[ (K_{\tau_2}^{\alpha_n'} - K_{\tau_1}^{\alpha_n'})^2 \right]^{1/3} .$$

The monotone convergence Theorem together with Jensen’s inequality and Relation (2.8) imply that

$$E[\eta_{\tau_1}^{\alpha_n'}] = \lim_{n \to \infty} \sup_{\alpha \in A_{\tau_1}^\gamma} E \left[ (K_{\tau_2}^{\alpha_n'} - K_{\tau_1}^{\alpha_n'})^2 \right]^{1/3} < \infty .$$

Since $\eta_{\tau_1}^{\alpha_n'}$ is in addition non-negative, it is a.s. bounded. Hence, combining (2.11) and (4.6), we obtain for $\alpha' \in A_{\tau_1}^\gamma$

$$0 \leq E_{\tau_1} \left[ K_{\tau_2}^{\alpha'} - K_{\tau_1}^{\alpha'} \right] \leq C \left( E_{\tau_1, \tau_2}^{\alpha'} [Y_{\tau_2}^{\alpha'}] - Y_{\tau_1}^{\alpha'} \right)^{1/3} \leq C \left( E_{\tau_1}^{\alpha'} [\Phi(M_{\tau_1}^{\alpha'})] - Y_{\tau_1}^{\alpha'} \right)^{1/3} .$$

27
Taking the essential infimum in the above inequality and appealing to (2.6) leads to (2.10).

**Step 3. The uniqueness property for (2.8)-(2.9)-(2.10)-(2.11)**

Let us now consider a family \((\tilde{Y}^\alpha, \tilde{Z}^\alpha, \tilde{K}^\alpha)_{\alpha \in \mathcal{A}_0}\) of \(S_2 \times H_2 \times K_2\) satisfying (2.8)-(2.9)-(2.10)-(2.11). Then, (2.6) together with (2.9)-(2.11) applied to \((\tilde{Y}^\alpha, \tilde{Z}^\alpha, \tilde{K}^\alpha)_{\alpha \in \mathcal{A}_0}\) imply via a direct comparison argument that

\[
\mathcal{Y}^\alpha_t = \text{ess inf}_{\alpha' \in \mathcal{A}_t} \mathcal{E}_t^g(\Phi(M^\alpha_T)) \geq \tilde{Y}^\alpha_t, \quad \alpha \in \mathcal{A}_0, \quad 0 \leq t \leq T.
\]

On the other hand, following the exact same line of arguments as the one developed in Step 2 in order to derive (4.5), one easily shows that there exists a \(S_2\)-uniformly bounded family of processes \((\tilde{L}^\alpha)_{\alpha \in \mathcal{A}_0}\) such that

\[
\mathcal{E}_t^g(\Phi(M^\alpha_T)) - \tilde{Y}^\alpha_t = E_t \left[ \int_t^T \tilde{L}^\alpha_s d\tilde{K}^\alpha_s \right] \leq CE_t \left[ |\tilde{K}^\alpha_T - \tilde{K}^\alpha_t|^2 \right]^{1/2}
\]

for all \(\alpha \in \mathcal{A}_0, \ 0 \leq t \leq T, \) for some \(C > 0.\)

Now observe that (2.10), applied to \(\tilde{K}^\alpha,\) and the same arguments as in Lemma 4.1 provide the existence of \((\hat{\alpha}^n)_n \subset \mathcal{A}_0^0\) such that \(E_t[|\hat{K}^\alpha_T - \tilde{K}^\alpha_T|^2] \to 0, \mathbb{P}\)-a.s. Hence, (2.8) ensures that \(E_t[|\hat{K}^\alpha_T - \tilde{K}^\alpha_T|^2] \to 0.\) Since (2.11) implies \((\hat{Y}^\alpha_t, \hat{K}^\alpha_t) = (\tilde{Y}^\alpha_t, \tilde{K}^\alpha_t)\) for \(n \in \mathbb{N},\) we deduce

\[
\mathcal{E}_t^g(\Phi(M^\alpha_T)) - \hat{Y}^\alpha_t \leq CE_t \left[ |\hat{K}^\alpha_T - \tilde{K}^\alpha_T|^2 \right]^{1/2} \to_{n \to \infty} 0.
\]

Combined with (4.7), this shows that

\[
\hat{Y}^\alpha_t = \text{ess inf}_{\alpha' \in \mathcal{A}_t} \mathcal{E}_t^g(\Phi(M^\alpha_T)) = \mathcal{Y}^\alpha_t, \quad \alpha \in \mathcal{H}_2, \quad 0 \leq t \leq T.
\]

The fact that \((\hat{Z}^\alpha, \hat{K}^\alpha)_{\alpha \in \mathcal{A}_0} = (Z^\alpha, K^\alpha)_{\alpha \in \mathcal{A}_0}\) then follows from the uniqueness of the non-linear Doob-Meyer decomposition of [11, Theorem 3.3].

### 5 Appendix

We report here some standard results for Lipschitz BSDEs. The first one can be found in, e.g., Theorem 1.5 in [10]. The second one is proved for completeness, and by lack of a good reference.

**Proposition 5.1. (Stability for Lipschitz BSDEs)** Let \((Y^1, Z^1)\) and \((Y^2, Z^2)\) in \(S_2 \times H_2\) be solutions on \([0, T]\) of Lipschitz BSDEs associated to parameters \((\xi^1, g^1)\) ad \((\xi^2, g^2)\). Then the following stability result holds:

\[
\|Y^1 - Y^2\|_{S_2}^2 + \|Z^1 - Z^2\|_{H_2}^2 \\
\leq C \left( \|\xi^1 - \xi^2\|_{L_2}^2 + \int_0^T E |g^1 - g^2|^2 (t, Y^1, Z^1) dt \right),
\]

for some constant \(C > 0\) depending only on \(T\) and on the Lipschitz constants of \(g^1\) and \(g^2\).
Proposition 5.2. Let the conditions (Hₙ) hold. Then:

(i) There exists $C > 0$ which only depends on $K_g$ and $T$ such that
\[
\text{esssup}_{\xi \in \mathcal{L}_0([0,1])} |\mathcal{E}^g_t[\xi]| \leq C(1 + E_t \left[ |\chi_g|^2 \right]^{1/2}), \quad 0 \leq t \leq T.
\]

(ii) For some $\xi \in \mathcal{L}_2$ and $t \in [0, T]$, consider a family $(\xi^\varepsilon)_{\varepsilon \geq 0} \subset \mathcal{L}_0(\mathbb{R}^d)$ satisfying $|\xi^\varepsilon| \leq \xi$ and $\xi^\varepsilon \in L^0(\mathcal{F}_{(t+\varepsilon)\wedge T})$, for any $\varepsilon > 0$. Then, there exists a family $(\eta_\varepsilon)_{\varepsilon > 0} \subset \mathcal{L}_0(\mathbb{R})$ which converges to $0 \mathbb{P}$-a.s. as $\varepsilon \to 0$ such that
\[
|\mathcal{E}^g_{t,t+\varepsilon}[\xi^\varepsilon] - E_t[\xi^\varepsilon]| \leq \eta_\varepsilon, \quad \forall \varepsilon \in [0, T-t].
\]

(iii) Let $(\xi^\varepsilon)_{\varepsilon \geq 0}$ and $t \in [0, T]$ be as in (ii). Then, there exists a family $(\eta_\varepsilon)_{\varepsilon > 0} \subset \mathcal{L}_0(\mathbb{R})$ which converges to $0 \mathbb{P}$-a.s. as $\varepsilon \to 0$ such that
\[
|\mathcal{E}^g_{t-\varepsilon,t}[\xi^\varepsilon] - E_t[\xi^\varepsilon]| \leq \eta_\varepsilon, \quad \forall \varepsilon \in [0, t].
\]

Proof. a. We first prove (ii) (property (iii) being similar) using the standard linearization argument. Fix $t \in [0, T]$ and set $Y^\varepsilon := \mathcal{E}^g_{t,t+\varepsilon}[\xi^\varepsilon]$. Assumption (Hₙ) implies that we can find a family of predictable processes $(\rho^\varepsilon, \gamma^\varepsilon)$ with values in $[-K_g, K_g]^{d+1}$ such that
\[
L^\varepsilon Y^\varepsilon + \int_t^s L^\varepsilon_g(r, 0, 0)dr
\]
is a martingale on $[t, t + \varepsilon]$, with
\[
L^\varepsilon_s = 1 + \int_t^s \rho^\varepsilon L^\varepsilon_dr + \int_t^s \gamma^\varepsilon L^\varepsilon_dr W_r, \quad t \leq s \leq t + \varepsilon.
\]
In particular,
\[
\mathcal{E}^g_{t,t+\varepsilon}[\xi^\varepsilon] = L^\varepsilon_t Y^\varepsilon_t = E_t \left[ L^\varepsilon_{t+\varepsilon} \xi^\varepsilon + \int_t^{t+\varepsilon} L^\varepsilon_g(r, 0, 0)dr \right].
\]
Condition (Hₙ) and the assumption on $(\xi^\varepsilon)_{\varepsilon > 0}$ thus leads to
\[
|\mathcal{E}^g_{t,t+\varepsilon}[\xi^\varepsilon] - E_t[\xi^\varepsilon]| \leq \eta_\varepsilon,
\]
in which
\[
\eta_\varepsilon := E_t \left[ |\xi| L^\varepsilon_{t+\varepsilon} - L^\varepsilon_t | + \chi_g \int_t^{t+\varepsilon} L^\varepsilon_r dr \right].
\]
We have:
\[
|\eta_\varepsilon| \leq E_t[|\xi|^2]^{1/2} E_t[L^\varepsilon_{t+\varepsilon} - L^\varepsilon_t|^2]^{1/2} + E_t[|\chi_g|^2]^{1/2} E_t \left[ \left| \int_t^{t+\varepsilon} L^\varepsilon_r dr \right|^2 \right]^{1/2}
\]
\[
\leq E_t[|\xi|^2]^{1/2} E_t[L^\varepsilon_{t+\varepsilon} - L^\varepsilon_t|^2]^{1/2} + \varepsilon E_t[|\chi_g|^2]^{1/2} E_t \left[ \sup_{t \leq r \leq t+\varepsilon} |L^\varepsilon_r|^2 \right]^{1/2}.
\]
In addition,

\[ E_t[|L^\varepsilon_{t+\varepsilon} - L^\varepsilon_t|^2] \leq C E_t \left[ \int_t^{t+\varepsilon} |L^\varepsilon_r|^2 dr \right] \]

\[ \leq \varepsilon C E_t \left[ \sup_{t \leq r \leq t+\varepsilon} |L^\varepsilon_r|^2 \right]. \]

Hence,

\[ E_t[|L^\varepsilon_{t+\varepsilon} - L^\varepsilon_t|^2] \leq \varepsilon C \left( 1 + E_t \left[ \sup_{t \leq r \leq t+\varepsilon} |L^\varepsilon_r - L^\varepsilon_t|^2 \right] \right). \]

Since \( \gamma^\varepsilon \) and \( \rho^\varepsilon \) are bounded, the quantity \( \sup_{t \leq r \leq t+\varepsilon} E_t[|L^\varepsilon_{t+\varepsilon} - L^\varepsilon_t|^2] \) is uniformly bounded. Plugging back this estimate in (5.1) and recalling that \( \sup_{t \in [0,T]} E_t[|\xi|^2] \) is finite \( \mathbb{P} \)-a.s. we get that \( E_t[|\xi|^2]^{1/2} E_t[|L^\varepsilon_{t+\varepsilon} - L^\varepsilon_t|^2]^{1/2} \) tends to 0 uniformly in \( t, \mathbb{P} \)-a.s. as \( \varepsilon \) goes to 0. The second term of (5.1) can be estimated in the same way.

b. We now prove (i). Pick any \( t \in [0,T] \) and \( \xi \in L_0([0,1]) \). The same arguments as above yield

\[ |\xi^g_t[\xi]| \leq E_t \left[ L^\xi_T \xi + \int_t^T L^\xi_r g(r,0,0) dr \right] \leq E_t \left[ |L^\xi_T| + T |\chi_g| \sup_{t \leq r \leq T} |L^\xi_r| dr \right], \]

where \( L^\xi \) solves

\[ L^\xi_s = 1 + \int_t^s \rho^\varepsilon L^\xi_r dr + \int_t^s \gamma^\varepsilon L^\xi_r dW_r, \quad t \leq s \leq T, \]

for some predictable processes \( (\rho^\varepsilon, \gamma^\varepsilon) \) with values in \([-K_g, K_g]^{d+1}\). Hence,

\[ |\xi^g_t[\xi]| \leq E_t \left[ |L^\xi_T| + T |\chi_g| \sup_{t \leq r \leq T} |L^\xi_r| dr \right]. \]

Since \( (\rho^\varepsilon, \gamma^\varepsilon) \) are valued in \([-K_g, K_g]^{d+1}\), standard estimates imply that we can find \( C > 0 \), which only depends on \( K_g \) such that \( E_t \left[ \sup_{t \leq r \leq T} |L^\xi_r|^2 \right] \leq C^2 \mathbb{P} \)-a.s. The above leads to

\[ |\xi^g_t[\xi]| \leq (C + TC E_t \left[ |\chi_g|^2 \right]^{1/2}), \]

and the arbitrariness of \( \xi \in L_0([0,1]) \) concludes the proof. \( \square \)
