1Manuscript received 10 August 2015; revision accepted 18 November 2015.

The authors thank the Furniss Foundation, the American Orchid Society, the Hugh M. Matheson Family Fund, and the City of Coral Gables for supporting the Million Orchid Project and the Batchelor Foundation for supporting science education at Fairchild Tropical Botanic Garden. The authors also thank Fairchild Director Dr. C. Lewis and Fairchild Director of Education A. Padolf for developing the program concept; Fairchild Orchid Research Assistant J. Arce for his help with collecting photo vouchers and for technical support in the laboratory; University of Chicago undergraduate and Fairchild volunteer D. Weiss for her exceptional mentoring and laboratory support; R. Ricks for her commitment to the students and staff; and A. Noble and M. Litzinger for their critical support with the internship logistics.

• **Premise of the study:** The Million Orchid Project at Fairchild Tropical Botanic Garden is an initiative to propagate native orchids for reintroduction into Miami’s urban landscapes. The aim of this study was to develop microsatellites for *Encyclia tampensis* and *Cyrtopodium punctatum* (Orchidaceae).

• **Methods and Results:** Ten microsatellites were developed for each species. For *E. tampensis* sampled from the natural population, allele numbers ranged from one to four, with an average observed heterozygosity ($H_o$) of 0.314 and average expected heterozygosity ($H_e$) of 0.281. For the individuals from cultivation, allele numbers ranged from one to six, with an average $H_o$ of 0.35 and an average $H_e$ of 0.224. For *C. punctatum*, allele numbers ranged from one to three, with an average $H_o$ of 0.257 and an average $H_e$ of 0.272.

• **Conclusions:** These microsatellites will be used to assess the genetic diversity of natural and cultivated populations with the intention of guiding genetic breeding under the Million Orchid Project.

**Key words:** commercially exploited plants; *Cyrtopodium punctatum*, *Encyclia tampensis*; microsatellites; native Florida orchids; Orchidaceae.

Fairchild Tropical Botanic Garden’s Million Orchid Project (hereafter FTBG and MOP) is a special initiative to reintroduce millions of exploited and threatened native orchids into the urban landscapes of the Miami metropolitan area. The project focuses on reestablishment in schoolyards, roadways, and other public spaces. The focal species for this study, *Encyclia tampensis* (Lindl.) Small and *Cyrtopodium punctatum* (L.) Lindl. (Orchidaceae), were selected for reintroduction through the MOP based on their conservation importance, potential to be grown epiphytically in street trees, and their history of human exploitation. Through volunteer and student efforts, this program has propagated thousands of orchids for reintroduction. However, the genetic diversity of existing wild and cultivated populations of these species in the region is unknown. *Encyclia tampensis*, also known as the butterfly orchid, is an epiphytic orchid native to southern Florida, Cuba, and The Bahamas (Luer, 1972). In southern Florida, it is found primarily in cypress swamps and tropical hammocks. The flowers, which look like butterflies, have varying amounts of red, green, and yellow hues in the petals (Subrahmanyam, 2008). The flowering period of *E. tampensis* in southern Florida is from May through August (Luer, 1972). In Florida, this species is considered commercially exploited according to a Florida state statute (Stat. No. 581.185 subsection 2(a); http://www.leg.state.fl.us/statutes/), suggesting that this species is subject to removal from the wild to be sold commercially.

*Cyrtopodium punctatum*, also known as the cigar or Florida cowhorn orchid, is a state-listed endangered orchid species native to southern Florida (Luer, 1972; Wunderlin et al., 2016). Wild populations of *C. punctatum* are also found in Mexico, the West Indies, and Central and South America (Romero-González and Fernández-Concha, 1999). *Cyrtopodium punctatum* is one of the only epiphytic species in the genus *Cyrtopodium* R. Br.,...
and in Florida is commonly found in cypress swamps and tropical hardwood hammocks (Chafin, 2000; Dutra et al., 2009). This orchid is characterized by bright yellow flowers splattered with dark burgundy spots and large pseudobulbs formed by former leaf bases. Populations have been degraded in southern Florida as a result of historic poaching, which has led to the legal protection of *C. punctatum* today (Stat. No. 581.185 subsection 2(a); [http://www.leg.state.fl.us/statutes/](http://www.leg.state.fl.us/statutes/)).

The objectives of this study were to develop microsatellite markers for each species and assess the degree of genetic diversity of the existing populations at FTBG used in propagation efforts. These microsatellites were also tested for efficacy on two congeneric species for each focal species available at FTBG; congeneric species included *E. alta* (Bateman) Schltr., *Encyclia* hybrid 'Cindy' Das Orch. (*E. tampensis × E. alata*), *C. macrobulbon* (La Llave & Lex.) G. A. Romero-González & Carnevali, and *G. flavum* Link & Otto ex Rchb.

**METHODS AND RESULTS**

Leaf tissue was collected from one plant of *E. tampensis* (accession no. 160744) and one plant of *C. punctatum* (accession no. 160984) for next-generation sequencing; both individuals are located at FTBG (Coral Gables, Florida, USA). Due to the rarity of these species and potential for poaching, GPS coordinates are not given for any individual plants in this study. Photo vouchers for each individual are deposited in the FTBG Herbarium (Coral Gables, Florida, USA). Genomic DNA was extracted from lyophilized tissue using the DNeasy Plant Mini Kit (QIAGEN, Venlo, The Netherlands) at FTBG laboratories. The total DNA was sent to the Georgia Genomics Facility at the University of Georgia (Athens, Georgia, USA) for next-generation sequencing using Illumina HiSeq 2000 (Illumina, San Diego, California, USA). The resulting 100-bp Illumina sequences were screened using the PERL script program PAL_FINDER_v0.02.03 to identify potential microsatellite repeat elements among the reads (Castoe et al., 2012). No additional sequencing was done after the Illumina run. Microsatellite repeats were detected in one direction; if one was found, the sequence was sent automatically to Primer3 version 2.0.0 primer pairs: 12 μL of genomic DNA, 11.5 μL of ddH₂O, and 10 μL of a primer mix; the total mixture included seven PCR primer pairs were manufactured at Integrated DNA Technologies (Coralville, Iowa, USA). These unlabeled primers were screened for unique products on the same individuals used for next-generation sequencing. The PCR products were prepared using 1 μL of genomic DNA, 11.5 μL of ddH₂O, 2.5 μL of TBT PAR (solution contains 750 mM trehalose [Sigma-Aldrich, St. Louis, Missouri, USA], 1 mg/mL nonacetylated bovine serum albumin [BSA; Sigma-Aldrich], 1% Tween-20 [Acros Organics, Geel, Belgium], and 8.5 mM Tris hydrochloride [pH 8.0: Fisher Scientific, Pittsburgh, Pennsylvania, USA]), and a 10-μL mixture of the primer pairs (10 μM concentration) using a Dyad Peltier Thermal Cycler (Bio-Rad Laboratories, Hercules, California, USA). The PCR conditions were as follows: initial denaturation at 94°C for 3 min; followed by 32 cycles of 94°C for 1 min, annealing for 1 min (temperature varied by species), and 72°C for 2 min; and elongation at 72°C for 30 min. Annealing temperatures were 62°C for the *E. tampensis* primer mix and 58°C for the *C. punctatum* primer mix (Tables 1 and 2). The PCR products were scored for presence or absence of a single appropriately sized DNA fragment using gel electrophoresis on 2% agarose gel. Based on these criteria, 13 and 11 of the 48 potential loci for *E. tampensis* and *C. punctatum*, respectively, were selected for dye-labeling at Applied Biosystems (Foster City, California, USA). Fragment analysis was then used to further detect any primer pairs that did not produce the expected PCR product, and any locus that showed multiple and/or overlapping peaks was omitted. For each species, the 10 best novel microsatellite loci were selected for their repeatability, potential polymorphism, and capacity for multiplexing (Tables 1 and 2).

Under these PCR conditions, 10 primers were then tested for polymorphism on a total of 20 individuals of *E. tampensis* from natural and cultivated sources, as well as one individual of *E. alata* and one individual of *Encyclia* hybrid 'Cindy'. Sampling for the natural population at FTBG consisted of 14 individuals, and the cultivated population was represented by six individuals. Cultivated individuals were obtained from a commercial nursery in Miami-Dade County, Florida. Ten primer pairs containing microsatellite regions were screened on 21 individuals of *C. punctatum*, two individuals of *C. macrobulbon*, and one individual of *C. flavum*. The PCR reactions consisted of 1 μL of genomic DNA, 14 μL of ddH₂O, and 10 μL of a primer mix; the total mixture included seven primer pairs: 12 μL of Y01, 24 μL of Y02, 36 μL of Y03, 24 μL of B01, 36 μL of B02 of 4°C for all loci.

http://www.bioone.org/loi/apps
Here we report 10 novel microsatellite loci each for two commercially exploited native Florida orchids, *E. tampensis* and *C. punctatum*. The microsatellites developed showed monomorphic and polymorphic differences in the two study populations, as well as some applicability for closely related taxa. Based on the number of alleles amplified and the average *H*<sub>o</sub> values for *E. tampensis*, these results suggest that the cultivated population is more genetically diverse than the natural population at FTBG; however, this conclusion is given with caution, because our sampling effort (number of plants sampled) was not representative of the entire population, and only one locus showed amplification of six alleles in the cultivated population. Allele numbers for the other *Encyclia* species were comparable to that of the *E. tampensis* natural population. The genetic diversity of *C. punctatum* individuals at FTBG, on average, was not significantly different than the *H*<sub>e</sub> (<2% difference). Because *C. punctatum* is an outcrossing species and the individuals sampled included several seedling volunteers, these findings indicate that an adequate amount of outcrossing is occurring in the garden population. Considering this evidence and the rarity of this species, this population may be an important source of diverse genetic material for diversifying the more vulnerable natural populations.

The resulting markers will be used to evaluate the genetic diversity, population demography, and potential gene flow of the remaining natural and cultivated populations in the region, with the intention of guiding the genetic breeding protocols for future reintroductions under the MOP. Specifically, we will assess the genetic diversity of all known individuals of *C. punctatum* and *E. tampensis* at FTBG. To ensure sufficiently diverse individuals are being selected for reintroduction, we will also screen offspring propagated from natural or artificial fruit set to be used for the MOP. More broadly, these microsatellite markers can be used to study genetic diversity of other populations within Miami and will be imperative in any future conservation efforts for these endangered orchid species.
