Dietary Supplement Use in Children and Adolescents Aged ≤19 Years — United States, 2017–2018

Bryan Stierman, MD1,2; Suruchi Mishra, PhD1; Jaime J. Gahche, PhD3; Nancy Potischman, PhD3; Craig M. Hales, MD1

Dietary supplement use is common among children and adolescents. During 2013–2014, approximately one third of children and adolescents (persons aged ≤19 years) in the United States were reported to use a dietary supplement in the past 30 days, and use varied by demographic characteristics (1,2). Dietary supplements can contribute substantially to overall nutrient intake, having the potential to both mitigate nutrient shortfalls as well as to lead to nutrient intake above recommended upper limits (3). However, because nutritional needs should generally be met through food consumption according to the 2015–2020 Dietary Guidelines for Americans, only a few dietary supplements are specifically recommended for use among children and adolescents and only under particular conditions (4). The most recently released data from the National Health and Nutrition Examination Survey (NHANES) during 2017–2018 were used to estimate the prevalence of use among U.S. children and adolescents of any dietary supplement, two or more dietary supplements, and specific dietary supplement product types. Trends were calculated for dietary supplement use from 2009–2010 to 2017–2018. During 2017–2018, 34.0% of children and adolescents used any dietary supplement in the past 30 days, with no significant change since 2009–2010. Use of two or more dietary supplements increased from 4.3% during 2009–2010 to 7.1% during 2017–2018. Multivitamin-mineral products were used by 23.8% of children and adolescents, making these the products most commonly used. Because dietary supplement use is common, surveillance of dietary supplement use, combined with nutrient intake from diet, will remain an important component of monitoring nutritional intake in children and adolescents to inform clinical practice and dietary recommendations.

NHANES is a cross-sectional survey designed to monitor the health and nutrition of the civilian noninstitutionalized resident U.S. population (https://www.cdc.gov/nchs/nhanes/index.htm).

The survey was approved by the National Center for Health Statistics Research Ethics Review Board. Signed consent from parents/guardians or participants aged ≥18 years, as well as documented assent from minor participants aged 7–17 years,
were obtained. Information on dietary supplement use was obtained during an in-home interview. Participants aged ≥16 years and emancipated minors were interviewed directly. An adult proxy provided information for participants aged <16 years. Participants were asked to show product containers for all dietary supplements taken in the past 30 days. The interviewer recorded information from the product labels. The NHANES interview response rate for children and adolescents during 2017–2018 was 59.3%.

Age groups were categorized as <2, 2–5, 6–11, and 12–19 years. Self-reported race and Hispanic origin were divided into five categories: non-Hispanic White, non-Hispanic Black, non-Hispanic Asian, Hispanic, and “other.” The “other” category included non-Hispanic persons reporting other races or more than one race and was included in total estimates but not shown separately. Family income was categorized as ≤130%, >130% to ≤350%, and >350% of the federal poverty level (FPL) which accounts for inflation, family size, and geographic location. Highest educational attainment of the household head was divided into three categories: less than high school, high school graduate or equivalent or some college or an associate degree, and college graduate or above. All products were classified using mutually exclusive categories in the following order: 1) multivitamin-mineral products containing ≥3 vitamins and ≥1 mineral; 2) products containing primarily calcium with or without other ingredients; 3) products containing primarily omega-3 fatty acids with or without other ingredients; 4) products containing primarily probiotics with or without other ingredients; 5) products containing primarily fiber with or without other ingredients; 6) products containing primarily melatonin with or without other ingredients; 7) botanical products containing ≥1 botanical ingredient and no vitamins or minerals; 8) multivitamins containing ≥2 vitamins with no minerals; 9) amino acid products containing ≥1 amino acid; and 10) single nutrient supplements, categorized separately, such as single vitamins (e.g., vitamin D, vitamin C) and single minerals (e.g., iron). Results are presented for the product types most frequently used by children and adolescents, i.e., those with ≥1% prevalence of use.

Two participants with missing dietary supplement use data were excluded from analysis. All other 2017–2018 NHANES participants aged ≤19 years comprised the sample (n = 3,683). Analyses used 2-year interview weights and accounted for the survey’s complex, multistage probability design. Standard errors for proportions were calculated using Taylor series linearization, and 95% confidence intervals were constructed using the Korn and Graubard method. Reliability of estimates was assessed using the National Center for Health Statistics Data Presentation Standards for Proportions. Differences in dietary supplement use by sex, age group, and race and Hispanic origin were evaluated using univariate two-sided t-statistics. Trends across income and education of household head were tested using linear regression including categories as continuous variables. Recent
trends over the last 10 years from 2009–2010 to 2017–2018 were tested using orthogonal polynomial regression with 2-year NHANES cycles. Differences in product use by age group were tested using F-based second-order Rao-Scott tests. All reported differences are statistically significant (p<0.05). All analyses were performed using R (version 3.6.0; R Foundation for Statistical Computing), SAS (version 9.4; SAS Institute), and SUDAAN (version 11; RTI International).

During 2017–2018, overall prevalence of dietary supplement use among children and adolescents in the preceding 30 days was 34.0% (Table 1). Supplement use among females (37.3%) was higher than that among males (30.8%), and use prevalence was highest among those aged 2–5 years (43.3%) followed by those aged 6–11 years (37.5%), 12–19 years (29.7%), and <2 years (21.8%). Prevalence was higher among non-Hispanic Asian (41.1%) and non-Hispanic White children and adolescents (39.9%) compared with that among non-Hispanic Black (20.8%) and Hispanic (26.9%) children and adolescents. Dietary supplement use increased with increasing income and education of the head of household. Prevalence of use of two or more dietary supplements was 7.1% and varied by age, race and Hispanic origin, income, and education of the head of household.

Among persons aged 12–19 years, use of any dietary supplement increased significantly in a linear fashion from 2009–2010 (22.1%) to 2017–2018 (29.7%) (Figure). Use of two or more dietary supplements increased significantly from 2009–2010 to 2017–2018 among all children and adolescents (from 4.3% to 7.1%) as well as among those aged 2–5 years (from 6.8% to 8.3%) and 12–19 years (from 3.2% to 8.5%).

Multivitamin-minerals were the most used product type (23.8% of children and adolescents) (Table 2). Prevalence of use of single ingredient vitamin D (3.6%), single ingredient vitamin C (3.0%), probiotic (1.8%), melatonin (1.3%), omega-3 fatty acid (1.3%), botanical (1.1%), and multivitamin (1.0%) products all met or exceeded 1.0%. Multivitamin-mineral, single ingredient vitamin D, probiotic, and botanical product use differed by age group.

### TABLE 1. Prevalence of any dietary supplement use and use of two or more dietary supplements in the past 30 days among children and adolescents (persons aged ≤19 years), by selected characteristics — United States, 2017–2018

| Characteristic                           | No.   | Any dietary supplement | ≥2 dietary supplements |
|-----------------------------------------|-------|------------------------|------------------------|
| Total                                    | 3,683 | 34.0 (30.2–37.9)       | 7.1 (5.6–8.9)          |
| Sex                                      |       |                        |                        |
| Female                                  | 1,829 | 37.3 (33.7–41.0)       | 7.7 (5.9–9.8)          |
| Male                                     | 1,854 | 30.8 (25.2–36.9)*      | 6.5 (4.5–9.2)          |
| Age group (yrs)                          |       |                        |                        |
| <2                                      | 591   | 21.8 (16.3–28.2)       | 2.4 (0.6–6.1)†         |
| 2–5                                     | 784   | 43.3 (37.6–49.2)§       | 8.3 (6.1–10.9)§        |
| 6–11                                    | 1,115 | 37.5 (33.5–41.6)§,¶     | 5.9 (3.6–8.9)          |
| 12–19                                   | 1,193 | 29.7 (24.1–35.7)§,¶,**  | 8.5 (5.9–11.6)§        |
| Race, Hispanic origin                    |       |                        |                        |
| White, non-Hispanic                      | 1,214 | 39.9 (33.5–46.5)†,§,§§ | 8.6 (5.9–11.9)††       |
| Black, non-Hispanic                      | 816   | 20.8 (16.4–25.8)       | 1.8 (0.7–3.7)          |
| Asian, non-Hispanic                      | 357   | 41.1 (32.1–50.6)†,§,§§ | 9.3 (5.3–14.8)††       |
| Hispanic                                 | 935   | 26.9 (20.9–33.6)       | 6.0 (3.6–9.2)††        |
| Family income relative to poverty level  |       |                        |                        |
| ≤130% of FPL                             | 1,328 | 23.5 (16.6–31.7)       | 4.0 (1.9–7.2)†         |
| >130% to ≤350% of FPL                    | 1,209 | 34.5 (29.2–40.2)       | 7.0 (5.5–8.7)          |
| >350% of FPL                             | 706   | 45.9 (39.2–52.8)¶¶      | 11.1 (6.7–17.0)¶¶      |
| Education of household head              |       |                        |                        |
| Less than high school graduation or equivalent | 638   | 17.8 (11.9–25.0)       | 1.8 (0.6–4.2)          |
| High school graduation or equivalent or some college or associate degree | 2,030 | 33.7 (29.0–38.6)       | 6.9 (5.2–8.8)          |
| College graduate or above                | 788   | 46.0 (39.3–52.9)***     | 10.8 (7.6–14.6)***     |

Abbreviation: CI = confidence interval.
* p-values calculated using F-based second-order Rao-Scott test.

Discussion

During 2017–2018, approximately one third of children and adolescents used dietary supplements in the past 30 days. Prevalence among female children and adolescents exceeded that among males. Sex-differences in any dietary supplement use among all children and adolescents combined have not been reported previously; however, a 2013–2014 study found a large, non-significant difference in any dietary supplement use among adolescent females and males (1). As previously reported, dietary supplement use prevalence increased with income and education of household head (2). Patterns of dietary supplement use by age group and race and Hispanic origin also remained similar (2).

Use of two or more dietary supplements varied by age group, race and Hispanic origin, income, and education of household head and increased from 2009–2010 to 2017–2018. Few studies have examined use of multiple dietary supplements in children and adolescents. Dietary supplements may contain 100% or more of daily nutrient intake recommendations (7); therefore, use of two or more dietary supplements could lead to intakes above recommended upper limits if the products contain any of the same ingredients. Future studies could examine common combinations of dietary supplements used and their contribution to overall nutrient intake.

As with previous studies, multivitamin-minerals were the most frequently used dietary supplement products (1,2). Use of some product types varied by age. A recent study found that among U.S. children and adolescents who use dietary supplements, 18% took a dietary supplement under the recommendation of a health care provider (2). Few dietary supplement products are recommended for use among children and adolescents, and these are recommended only under specific circumstances. For example, the American Academy of Pediatrics (AAP) recommends that breastfeeding infants ages >4 months receive iron supplementation until introduction of iron-containing complementary foods and that all exclusively breastfed infants receive vitamin D supplementation (8,9).

Other circumstances warranting dietary supplement use in children or adolescents include restrictive diets, pregnancy, and various illnesses. The 2015–2020 Dietary Guidelines for Americans recommend that nutritional needs be met primarily through food consumption; however, it recognizes that dietary supplements might be useful in some cases to compensate for nutrients that would otherwise be underconsumed (4). Dietary supplement use might mitigate nutrient shortfalls but might also lead to intake above recommended upper limits for some nutrients (3). AAP recommends that pediatric health care providers inquire about dietary supplement use among patients (10).

The findings in this report are subject to at least two limitations. First, the low prevalence of use of two or more dietary supplements make these estimates less reliable among some subgroups. Second, the lack of universal definitions for dietary supplement product types limits comparisons across studies.

Dietary supplement use is fairly prevalent among U.S. children and adolescents and contributes to overall total nutrient intake. NHANES will continue to measure dietary supplement use among children and adolescents to inform clinical practice and dietary recommendations.

Summary

What is already known about this topic?
Approximately one third of U.S. children and adolescents take dietary supplements; use varies by demographic characteristics.

What is added by this report?
The most recently released dietary supplement use estimates from the 2017–2018 National Health and Nutrition Examination Survey (NHANES) demonstrate that dietary supplement use remained stable and prevalent among U.S. children and adolescents aged ≤19 years (34.0%). Use of two or more dietary supplements differed by demographic characteristics and increased from 2009–2010 (4.3%) to 2017–2018 (7.1%).

What are the implications for public health practice?
NHANES will continue to measure dietary supplement use among children and adolescents to inform clinical practice and dietary recommendations.
dietary supplement use among children and adolescents to help inform clinical practice and policy, such as the Dietary Guidelines for Americans.
