Ray-Singer type theorem for the refined analytic torsion

Braverman, M ; Kappeler, T

Abstract: We show that the refined analytic torsion is a holomorphic section of the determinant line bundle over the space of complex representations of the fundamental group of a closed oriented odd-dimensional manifold. Further, we calculate the ratio of the refined analytic torsion and the Farber–Turaev combinatorial torsion. As an application, we establish a formula relating the eta-invariant and the phase of the Farber–Turaev torsion, which extends a theorem of Farber and earlier results of ours. This formula allows to study the spectral flow using methods of combinatorial topology.

RAY-SINGER TYPE THEOREM FOR THE REFINED ANALYTIC TORSION

MAXIM BRAVERMAN† AND THOMAS KAPPELER‡

Abstract. We show that the refined analytic torsion is a holomorphic section of the determinant line bundle over the space of complex representations of the fundamental group of a closed oriented odd dimensional manifold. Further, we calculate the ratio of the refined analytic torsion and the Turaev combinatorial torsion.

As an application, we establish a formula relating the eta-invariant and the phase of the Turaev torsion, which extends a theorem of Farber and earlier results of ours. This formula allows to study the spectral flow using methods of combinatorial topology.

1. Introduction

Let $M$ be a closed oriented odd dimensional manifold. Denote by $\text{Rep}(\pi_1(M), \mathbb{C}^n)$ the space of $n$-dimensional complex representations of the fundamental group $\pi_1(M)$ of $M$. For $\alpha \in \text{Rep}(\pi_1(M), \mathbb{C}^n)$ we denote by $E_\alpha$ the flat vector bundle over $M$ whose monodromy is equal to $\alpha$. Let $\nabla_\alpha$ be the flat connection on $E_\alpha$. In [4], we defined the non-zero element $\rho_\text{an}(\alpha) = \rho_\text{an}(\nabla_\alpha) \in \text{Det}(H^\bullet(M, E_\alpha))$ of the determinant line $\text{Det}(H^\bullet(M, E_\alpha))$ of the cohomology $H^\bullet(M, E_\alpha)$ of $M$ with coefficients in $E_\alpha$. This element, called the refined analytic torsion, carries information about the Ray-Singer metric and about the $\eta$-invariant. In particular, if $\alpha$ is a unitary representation, then the Ray-Singer norm of $\rho_\text{an}(\alpha)$ is equal to 1.

Analyticity of the refined analytic torsion. The disjoint union of the lines $\text{Det}(H^\bullet(M, E_\alpha))$, $(\alpha \in \text{Rep}(\pi_1(M), \mathbb{C}^n))$, forms a line bundle $\text{Det} \to \text{Rep}(\pi_1(M), \mathbb{C}^n)$, called the determinant line bundle, cf. [1] §9.7. It admits a nowhere vanishing section, given by the Turaev torsion, and, hence, has a natural structure of a trivializable holomorphic bundle.

Our first result is that $\rho_\text{an}(\alpha)$ is a nowhere vanishing holomorphic section of the bundle $\text{Det}$. It means that the ratio of the refined analytic and the Turaev torsions is a holomorphic function on $\text{Rep}(\pi_1(M), \mathbb{C}^n)$. For an acyclic representation $\alpha$, the determinant line $\text{Det}(H^\bullet(M, E_\alpha))$ is canonically isomorphic to $\mathbb{C}$ and $\rho_\text{an}(\alpha)$ can be viewed as a non-zero complex number. We show that $\rho_\text{an}(\alpha)$ is a holomorphic function on the open set $\text{Rep}_0(\pi_1(M), \mathbb{C}^n) \subset \text{Rep}(\pi_1(M), \mathbb{C}^n)$ of

acyclic representations. This result extends Corollary 13.11 of [4]. See also [8] for somewhat related results.

Comparison with the Turaev torsion. In [20, 21], Turaev constructed a refined version of the combinatorial torsion associated to a representation $\alpha$, which depends on additional combinatorial data, denoted by $\varepsilon$ and called the Euler structure, as well as on the cohomological orientation of $M$, i.e., on the orientation $\sigma$ of the determinant line of the cohomology $H^\bullet(M, \mathbb{R})$ of $M$. In [11], the Turaev torsion was redefined as a non-zero element $\rho_{\varepsilon, \sigma}(\alpha)$ of the determinant line $\text{Det} (H^\bullet(M, E_\alpha))$.

Theorem 5.11 of this paper states, that for each connected component $\mathcal{C}$ of the space $\text{Rep}(\pi_1(M), \mathbb{C}^n)$, there exists a constant $\theta \in \mathbb{R}$, such that

$$\frac{\rho_{\text{an}}(\alpha)}{\rho_{\varepsilon, \sigma}(\alpha)} = e^{i\theta} \cdot f_{\varepsilon, \sigma}(\alpha),$$

(1.1)

where $f_{\varepsilon, \sigma}(\alpha)$ is a holomorphic function of $\alpha \in \text{Rep}(\pi_1(M), \mathbb{C}^n)$, given by an explicit local expression, cf. (5.8). In the case where $\alpha$ is an acyclic representation close to an acyclic unitary representation, this formula was obtained in [3].

Recently, Rung-Tzung Hunag [15] showed by an explicit calculation for lens spaces that the constant $\theta$ might depend on the connected component $\mathcal{C}$.

Sketch of the proof of formula (1.1). Using the calculation of the Ray-Singer norm of the Turaev torsion, given in Theorem 10.2 of [11] and the formula for the Ray-Singer norm of the refined analytic torsion [4, Th. 11.3], we obtain (cf. (5.16)) that

$$\left| \frac{\rho_{\text{an}}(\alpha)}{\rho_{\varepsilon, \sigma}(\alpha)} \right| = |f_{\varepsilon, \sigma}(\alpha)|.$$

(1.2)

Both, the left and the right hand side of this equality, are absolute values of holomorphic functions. If the absolute values of two holomorphic functions are equal, then the two functions are equal up to a multiplication by a locally constant function, whose absolute value is equal to one. Hence, (1.1) follows from (1.2).

Application: relation of the $\eta$-invariant with the phase of the Turaev torsion. If $\alpha \in \text{Rep}(\pi_1(M), \mathbb{C}^n)$ is an acyclic unitary representation, then the refined analytic torsion $\rho_{\text{an}}(\alpha)$ is a non-zero complex number, whose phase is equal, up to a correction term, to the $\eta$-invariant $\eta_\alpha$ of the odd signature operator corresponding to the flat connection on $E_\alpha$, cf. (6.2). Hence, if $\alpha_1$ and $\alpha_2$ are two acyclic unitary representations which lie in the same connected component of $\text{Rep}(\pi_1(M), \mathbb{C}^n)$, equality (1.1) allows to compute the difference $\eta_{\alpha_1} - \eta_{\alpha_2}$ in terms of the phases of the Turaev torsions $\rho_{\varepsilon, \sigma}(\alpha_1)$ and $\rho_{\varepsilon, \sigma}(\alpha_2)$. The significance of this computation is that it allows to study the spectral invariant $\eta_\alpha$ by the methods of combinatorial topology. With

1In this paper we always consider the classical (not the Zariski) topology on the complex analytic space $\text{Rep}(\pi_1(M), \mathbb{C}^n)$.

2Note that since $\rho_{\text{an}}(\alpha)$ and $\rho_{\varepsilon, \sigma}(\alpha)$ are non-vanishing sections of the same bundle, their ratio is a non-zero complex-valued function.
some additional assumptions on $\alpha_1$ and $\alpha_2$ a similar result was established in [9] and [3], cf. Remark 6.5.

**Related works.** In [20, 21], Turaev constructed a refined version of the combinatorial torsion and posed the problem of constructing its analytic analogue - see also [11, §10.3]. The proposed notion of refined torsion gives an affirmative answer to this question in full generality.

Having applications in topology in mind, quite some time ago, Burghelea asked the question if there exists a holomorphic function on the subspace of acyclic representations $\text{Rep}_0(\pi_1(M), \mathbb{C}^n)$ whose absolute value is equal to the (modified) Ray-Singer torsion. In [7, 8], Burghelea and Haller constructed such a holomorphic function. In particular, in [8] they outlined a construction of this function which uses Laplace-type operators acting on forms obtained by replacing a Hermitian scalar product on a given complex vector bundle by a non-degenerate symmetric bilinear form. These operators are non self-adjoint and have complex-valued zeta-regularized determinants. The function constructed in [8] is similar to the invariant $\xi$ defined in §7 of our paper [3]. Burghelea and Haller then express the square of the Turaev torsion in terms of these determinants and some additional ingredients. Hence they obtain a formula for the Turaev torsion in terms of analytic quantities up to a sign. This result should be compared with formula (1.1), which expresses the Turaev torsion including its sign in analytic terms. The sign is important, in particular, for the application discussed in Section 6. Note that the result of Burghelea and Haller is valid on a manifold of arbitrary, not necessarily odd dimension. Their holomorphic function is different from our refined analytic torsion. In particular, it seems not to be related to the Atiyah-Patodi-Singer $\eta$-invariant.

2. The Refined Analytic Torsion

In this section we recall the definition of the refined analytic torsion from [4]. The refined analytic torsion is constructed in 3 steps: first, we define the notion of refined torsion of a finite dimensional complex endowed with a chirality operator, cf. Definition 2.3. Then we fix a Riemannian metric $g^M$ on $M$ and consider the odd signature operator $\mathcal{B} = \mathcal{B}(\nabla, g^M)$ associated to a flat vector bundle $(E, \nabla)$, cf. Definition 2.5. Using the graded determinant of $\mathcal{B}$ and the definition of the refined torsion of a finite dimensional complex with a chirality operator we construct an element $\rho = \rho(\nabla, g^M)$ in the determinant line of the cohomology, cf. (2.13). The element $\rho$ is almost the refined analytic torsion. However, it might depend on the Riemannian metric $g^M$ (though it does not if $\dim M \equiv 1 \pmod{4}$ or if $\text{rank}(E)$ is divisible by 4). Finally we “correct” $\rho$ by multiplying it by an explicit factor, the metric anomaly of $\rho$, to obtain a diffeomorphism invariant $\rho_{\text{an}}(\nabla)$ of the triple $(M, E, \nabla)$, cf. Definition 2.10.

2.1. The determinant line of a complex. Given a complex vector space $V$ of dimension $\dim V = n$, the determinant line of $V$ is the line $\text{Det}(V) := \Lambda^n V$, where $\Lambda^n V$ denotes the $n$-th exterior power of $V$. By definition, we set $\text{Det}(0) := \mathbb{C}$. Further, we denote by $\text{Det}(V)^{-1}$ the dual line of $\text{Det}(V)$.

Let $(C^\bullet, \partial) : 0 \to C^0 \xrightarrow{\partial} C^1 \xrightarrow{\partial} \cdots \xrightarrow{\partial} C^d \to 0$
be a complex of finite dimensional complex vector spaces. We call the integer $d$ the length of the complex $(C^\bullet, \partial)$ and we denote by $H^\bullet(\partial) = \bigoplus_{i=0}^{d} H^i(\partial)$ the cohomology of $(C^\bullet, \partial)$. Set
\[
\det(C^\bullet) := \bigotimes_{j=0}^{d} \det(C^j)(-1)^j, \quad \det(H^\bullet(\partial)) := \bigotimes_{j=0}^{d} \det(H^j(\partial))(1-1)^j. \tag{2.1}
\]
The lines $\det(C^\bullet)$ and $\det(H^\bullet(\partial))$ are referred to as the determinant line of the complex $C^\bullet$ and the determinant line of its cohomology, respectively. There is a canonical isomorphism
\[
\phi_{C^\bullet} = \phi_{(C^\bullet, \partial)} : \det(C^\bullet) \to \det(H^\bullet(\partial)), \tag{2.2}
\]
cf., for example, §2.4 of [2].

2.2. The refined torsion of a finite dimensional complex with a chirality operator. Let $d = 2r - 1$ be an odd integer and let $(C^\bullet, \partial)$ be a length $d$ complex of finite dimensional complex vector spaces. A chirality operator is an involution $\Gamma : C^\bullet \to C^\bullet$ such that $\Gamma(C^j) = C^{d-j}$, $j = 0, \ldots, d$. For $c_j \in \det(C^j)$ ($j = 0, \ldots, d$) we denote by $\Gamma c_j \in \det(C^{d-j})$ the image of $c_j$ under the isomorphism $\det(C^j) \to \det(C^{d-j})$ induced by $\Gamma$.

Fix non-zero elements $c_j \in \det(C^j)$, $j = 0, \ldots, r - 1$ and denote by $c_j^{-1}$ the unique element of $\det(C^j)^{-1}$ such that $c_j^{-1}(c_j) = 1$. Consider the element
\[
c_r := (-1)^{\mathcal{R}(C^\bullet)} \cdot c_0 \otimes c_1^{-1} \otimes \cdots \otimes c_{r-1}^{-1} \otimes (\Gamma c_{r-1})(-1)^r \otimes (\Gamma c_{r-2})(-1)^r \otimes \cdots \otimes (\Gamma c_0)^{-1} \quad \tag{2.3}
\]
of $\det(C^\bullet)$, where
\[
\mathcal{R}(C^\bullet) := \frac{1}{2} \sum_{j=0}^{r-1} \dim C^j \cdot \left( \dim C^j + (-1)^{r+j} \right). \tag{2.4}
\]
It follows from the definition of $c_j^{-1}$ that $c_r$ is independent of the choice of $c_j$ ($j = 0, \ldots, r - 1$).

**Definition 2.3.** The refined torsion of the pair $(C^\bullet, \Gamma)$ is the element
\[
\rho_r = \rho_{C^\bullet, \Gamma} := \phi_{C^\bullet}(c_r) \in \det\left( H^\bullet(\partial) \right), \tag{2.5}
\]
where $\phi_{C^\bullet}$ is the canonical map (2.2).

2.4. The odd signature operator. Let $M$ be a smooth closed oriented manifold of odd dimension $d = 2r - 1$ and let $(E, \nabla)$ be a flat vector bundle over $M$. We denote by $\Omega^k(M, E)$ the space of smooth differential forms on $M$ of degree $k$ with values in $E$ and by
\[
\nabla : \Omega^\bullet(M, E) \to \Omega^{\bullet+1}(M, E)
\]
the covariant differential induced by the flat connection on $E$.

Fix a Riemannian metric $g^M$ on $M$ and let $\ast : \Omega^\bullet(M, E) \to \Omega^{d-\bullet}(M, E)$ denote the Hodge $\ast$-operator. Define the chirality operator $\Gamma = \Gamma(g^M) : \Omega^\bullet(M, E) \to \Omega^\bullet(M, E)$ by the formula
\[
\Gamma \omega := i^r (-1)^{\frac{k(k+1)}{2}} \ast \omega, \quad \omega \in \Omega^k(M, E), \tag{2.6}
\]
with $r$ given as above by $r = \frac{d+1}{2}$. The numerical factor in (2.6) has been chosen so that $\Gamma^2 = 1$, cf. Proposition 3.58 of [1].
**Definition 2.5.** The odd signature operator is the operator

\[ B = B(\nabla, g^M) := \Gamma \nabla + \nabla \Gamma : \Omega^\bullet(M, E) \longrightarrow \Omega^\bullet(M, E). \quad (2.7) \]

We denote by \( B_k \) the restriction of \( B \) to the space \( \Omega^k(M, E) \).

2.6. The graded determinant of the odd signature operator. Note that for each \( k = 0, \ldots, d \), the operator \( B^2 \) maps \( \Omega^k(M, E) \) into itself. Suppose \( I \) is an interval of the form \([0, \lambda], (\lambda, \mu], \) or \((\lambda, \infty) \) \((\mu > \lambda \geq 0)\). Denote by \( \Pi_{B^2, I} \) the spectral projection of \( B^2 \) corresponding to the set of eigenvalues, whose absolute values lie in \( I \). Set

\[ \Omega^\bullet_{I}(M, E) := \Pi_{B^2, I}(\Omega^\bullet(M, E)) \subset \Omega^\bullet(M, E). \]

If the interval \( I \) is bounded, then, cf. Section 6.10 of \cite{4}, the space \( \Omega^\bullet_{I}(M, E) \) is finite dimensional.

For each \( k = 0, \ldots, d \), set

\[ \Omega^k_{+, I}(M, E) := \text{Ker}(\nabla \Gamma)^\perp \cap \Omega^k_I(M, E) = (\Gamma(\text{Ker} \nabla)) \cap \Omega^k_I(M, E); \]

\[ \Omega^k_{-, I}(M, E) := \text{Ker}(\Gamma \nabla)^\perp \cap \Omega^k_I(M, E) = \text{Ker} \nabla \cap \Omega^k_I(M, E). \quad (2.8) \]

Then

\[ \Omega^k_I(M, E) = \Omega^k_{+, I}(M, E) \oplus \Omega^k_{-, I}(M, E) \quad \text{if} \quad 0 \not\in I. \quad (2.9) \]

We consider the decomposition (2.9) as a grading\(^3\) of the space \( \Omega^\bullet_I(M, E) \), and refer to \( \Omega^k_{+, I}(M, E) \) and \( \Omega^k_{-, I}(M, E) \) as the positive and negative subspaces of \( \Omega^k_I(M, E) \).

Set

\[ \Omega^\text{even}_{I}(M, E) = \bigoplus_{p=0}^{r-1} \Omega^2p^\pm_I(M, E) \]

and let \( B^I \) and \( B^I_{\text{even}} \) denote the restrictions of \( B \) to the subspaces \( \Omega^\bullet_I(M, E) \) and \( \Omega^\text{even}_I(M, E) \) respectively. Then \( B^I_{\text{even}} \) maps \( \Omega^\text{even}_I(M, E) \) to itself. Let \( B^I_{\text{even}} \) denote the restriction of \( B^I_{\text{even}} \) to the space \( \Omega^\text{even}_{I}(M, E) \). Clearly, the operators \( B^I_{\pm I} \) are bijective whenever \( 0 \not\in I \).

**Definition 2.7.** Suppose \( 0 \not\in I \). The graded determinant of the operator \( B^I_{\text{even}} \) is defined by

\[ \text{Det}_{gr, \theta}(B^I_{\text{even}}) := \frac{\text{Det}_{\theta}(B^I_{\pm I})}{\text{Det}_{\theta}(-B^I_{\text{even}})} \in \mathbb{C}\setminus\{0\}, \quad (2.10) \]

where \( \text{Det}_{\theta} \) denotes the \( \zeta \)-regularized determinant associated to the Agmon angle \( \theta \in (-\pi, 0) \), cf., for example, §6 of \cite{1}.

It follows from formula (6.17) of \cite{1} that (2.10) is independent of the choice of \( \theta \in (-\pi, 0) \).

\(^3\)Note, that our grading is opposite to the one considered in \cite{2} §2.
2.8. The canonical element of the determinant line. Since the covariant differentiation \( \nabla \) commutes with \( \mathcal{B} \), the subspace \( \Omega_\bullet^*(M,E) \) is a subcomplex of the twisted de Rham complex \( (\Omega^\bullet(M,E), \nabla) \). Clearly, for each \( \lambda \geq 0 \), the complex \( \Omega^\bullet(\lambda, \infty)(M,E) \) is acyclic. Since
\[
\Omega^\bullet(M,E) = \Omega^\bullet(\lambda, \infty)(M,E) \oplus \Omega^\bullet(\lambda, \infty)(M,E),
\]
the cohomology \( H^\bullet(\lambda, \infty)(M,E) \) of the complex \( \Omega^\bullet(\lambda, \infty)(M,E) \) is naturally isomorphic to the cohomology \( H^\bullet(M,E) \).

Let \( \Gamma_\nabla \) denote the restriction of \( \Gamma \) to \( \Omega_\bullet^*(M,E) \). For each \( \lambda \geq 0 \), let
\[
\rho_{\Gamma_{\lambda}} = \rho_{\Gamma_{\lambda}}(\nabla, g^M) \in \text{Det}(H^\bullet(\lambda, \infty)(M,E))
\]
denote the refined torsion of the finite dimensional complex \( (\Omega^\bullet(\lambda, \infty)(M,E), \nabla) \) corresponding to the chirality operator \( \Gamma_{\lambda} \), cf. Definition 2.3. We view \( \rho_{\Gamma_{\lambda}} \) as an element of \( \text{Det}(H^\bullet(M,E)) \) via the canonical isomorphism between \( H^\bullet(\lambda, \infty)(M,E) \) and \( H^\bullet(M,E) \).

It is shown in Proposition 7.8 of \cite{4} that the nonzero element
\[
\rho(\nabla) = \rho(\nabla, g^M) := \text{Det}_{\text{gr, } \theta}(\mathcal{B}_{\text{even}}(\lambda, \infty)) \cdot \rho_{\Gamma_{\lambda}} \in \text{Det}(H^\bullet(M,E))
\]
is independent of the choice of \( \lambda \geq 0 \). Further, \( \rho(\nabla) \) is independent of the choice of the Agmon angle \( \theta \in (-\pi, 0) \) of \( \mathcal{B}_{\text{even}} \).

If the odd signature operator is invertible then \( \text{Det}(H^\bullet(M,E)) \) is canonically isomorphic to \( \mathbb{C} \) and \( \rho_{\Gamma_{\lambda}} = 1 \). Hence, \( \rho(\nabla) \) is a complex number which coincides with the graded determinant \( \text{Det}_{\text{gr, } \theta}(\mathcal{B}_{\text{even}}) = \text{Det}_{\text{gr, } \theta}(\mathcal{B}_{\text{even}}^{0, \infty}) \). This case was studied in \cite{3}.

2.9. The refined analytic torsion. Since \( \text{dim } M \) is odd, there exists an oriented manifold \( N \) whose oriented boundary is the disjoint union of two copies of \( M \) (with the same orientation), cf. \cite{22}, \cite{18} Th. IV.6.5.

Definition 2.10. Let \( N \) be an oriented manifold whose oriented boundary is the disjoint union of two copies of \( M \) and let \( (E, \nabla) \) be a flat vector bundle on \( M \). The refined analytic torsion is the element
\[
\rho_{\text{an}}(\nabla) = \rho_{\text{an}}(\nabla, N) := \rho(\nabla, g^M) \cdot e^{\frac{i\text{rank } E}{2} \int_N L(p, g^M)} \in \text{Det}(H^\bullet(M,E)),
\]
where \( g^M \) is any Riemannian metric on \( M \), \( \rho(\nabla, g^M) \in \text{Det}(H^\bullet(M,E)) \) is defined in (2.13), and \( L(p, g^M) \) is the Hirzebruch L-polynomial in the Pontrjagin forms of any Riemannian metric on \( N \) which near \( M \) is the product of \( g^M \) and the standard metric on the half-line.

In particular, if \( \text{dim } M \equiv 1 \pmod{4} \), then \( \int_N L(p, g^M) = 0 \) and \( \rho_{\text{an}}(\nabla) = \rho(\nabla, g^M) \) is independent of the cobordism \( N \).

It is shown in Theorem 9.6 of \cite{4} that \( \rho_{\text{an}}(\nabla) \) is independent of \( g^M \). But, if \( \text{dim } M \equiv 3 \pmod{4} \), it does depend on the choice of the manifold \( N \). However, by Remark 9.9 of \cite{4}, \( \rho_{\text{an}}(\nabla) \) is independent of this choice up to multiplication by \( e^{k \text{rank } E} \) (\( k \in \mathbb{Z} \)). If \( \text{rank } E \) is even then \( \rho_{\text{an}}(\nabla) \) is canonically defined up to a sign, and if \( \text{rank } E \) is divisible by 4, then \( \rho_{\text{an}}(\nabla) \) is a canonically defined element of \( \text{Det}(H^\bullet(M,E)) \).
3. The Determinant Line Bundle over the Space of Representations

The space \( \text{Rep}(\pi_1(M), \mathbb{C}^n) \) of complex \( n \)-dimensional representations of \( \pi_1(M) \) has a natural structure of a complex analytic space, cf., for example, [3, §13.6]. The disjoint union

\[
\mathcal{D} \text{et} := \bigsqcup_{\alpha \in \text{Rep}(\pi_1(M), \mathbb{C}^n)} \text{Det} \left( H^\bullet(M, E^\alpha) \right)
\]

has a natural structure of a holomorphic line bundle over \( \text{Rep}(\pi_1(M), \mathbb{C}^n) \), called the determinant line bundle. In this section we describe this structure, using a CW-decomposition of \( M \). Then, by construction, the Turaev torsion \( \rho_{\varepsilon, o}(\alpha) \) is a nowhere vanishing holomorphic section of \( \mathcal{D} \text{et} \). In particular, it defines a holomorphic trivialization of \( \mathcal{D} \text{et} \). Note, however, that this trivialization is not canonical since it depends on the Euler structure \( \varepsilon \).

3.1. The flat vector bundle induced by a representation. Denote by \( \pi : \tilde{M} \to M \) the universal cover of \( M \) and by \( \pi_1(M) \) the fundamental group of \( M \), viewed as the group of deck transformations of \( \tilde{M} \to M \). For \( \alpha \in \text{Rep}(\pi_1(M), \mathbb{C}^n) \), we denote by \( E^\alpha := \tilde{M} \times_\alpha \mathbb{C}^n \to M \)

the flat vector bundle induced by \( \alpha \). Let \( \nabla^\alpha \) be the flat connection on \( E^\alpha \) induced from the trivial connection on \( \tilde{M} \times \mathbb{C}^n \). We will also denote by \( \nabla^\alpha \) the induced differential

\[
\nabla^\alpha : \Omega^\bullet(M, E^\alpha) \to \Omega^{\bullet+1}(M, E^\alpha),
\]

where \( \Omega^\bullet(M, E^\alpha) \) denotes the space of smooth differential forms of \( M \) with values in \( E^\alpha \).

For each connected component (in classical topology) \( C \) of \( \text{Rep}(\pi_1(M), \mathbb{C}^n) \), all the bundles \( E^\alpha, \alpha \in C \), are isomorphic, see e.g. [13].

3.2. The combinatorial cochain complex. Fix a CW-decomposition \( K = \{ e_1, \ldots, e_N \} \) of \( M \). For each \( j = 1, \ldots, N \), fix a lift \( \tilde{e}_j \), i.e., a cell of the CW-decomposition of \( \tilde{M} \), such that \( \pi(\tilde{e}_j) = e_j \). By [32], the pull-back of the bundle \( E^\alpha \) to \( \tilde{M} \) is the trivial bundle \( \tilde{M} \times \mathbb{C}^n \to \tilde{M} \).

Hence, the choice of the cells \( \tilde{e}_1, \ldots, \tilde{e}_N \) identifies the cochain complex \( C^\bullet(K, \alpha) \) of the CW-complex \( K \) with coefficients in \( E^\alpha \) with the complex

\[
0 \to \mathbb{C}^{n \cdot k_0} \xrightarrow{\partial_0(\alpha)} \mathbb{C}^{n \cdot k_1} \xrightarrow{\partial_1(\alpha)} \cdots \xrightarrow{\partial_{d-1}(\alpha)} \mathbb{C}^{n \cdot k_d} \to 0,
\]

where \( k_j \in \mathbb{Z}_{\geq 0} \) (\( j = 0, \ldots, d \)) is equal to the number of \( j \)-dimensional cells of \( K \) and the differentials \( \partial_j(\alpha) \) are \((nk_j \times nk_{j-1})\)-matrices depending analytically on \( \alpha \in \text{Rep}(\pi_1(M), \mathbb{C}^n) \).

The cohomology of the complex [33] is canonically isomorphic to \( H^\bullet(M, E^\alpha) \). Let

\[
\phi_{C^\bullet(K, \alpha)} : \text{Det} \left( C^\bullet(K, \alpha) \right) \to \text{Det} \left( H^\bullet(M, E^\alpha) \right)
\]

denote the isomorphism [22].
3.3. The holomorphic structure on $\Det$. The standard bases of $\mathbb{C}^{n-k_j}$ ($j = 0, \ldots, d$) define an element $c \in \Det (C^\bullet(K, \alpha))$, and, hence, an isomorphism

$$\psi: \mathbb{C} \to \Det (C^\bullet(K, \alpha)), \quad z \mapsto z \cdot c.$$ 

Then the map

$$\sigma: \alpha \mapsto \phi_{C^\bullet(K, \alpha)} (\psi(1)) \in \Det (H^\bullet(M, E_\alpha)), \quad \alpha \in \Rep(\pi_1(M), \mathbb{C}^n)$$

is a nowhere vanishing section of the determinant line bundle $\Det$ over $\Rep(\pi_1(M), \mathbb{C}^n).

**Definition 3.4.** We say that a section $s(\alpha)$ of $\Det$ is holomorphic if there exists a holomorphic function $f(\alpha)$ on $\Rep(\pi_1(M), \mathbb{C}^n)$, such that $s(\alpha) = f(\alpha) \cdot \sigma(\alpha)$.

This defines a holomorphic structure on $\Det$, which is independent of the choice of the lifts $\bar{e}_1, \ldots, \bar{e}_N$ of $e_1, \ldots, e_N$, since for a different choice of lifts the section $\sigma(\alpha)$ will be multiplied by a constant. In the next subsection we show that this holomorphic structure is also independent of the CW-decomposition $K$ of $M$.

3.5. The Turaev torsion. The choice of the lifts $\bar{e}_1, \ldots, \bar{e}_N$ of $e_1, \ldots, e_N$ determines an Euler structure on $M$, while the ordering of the cells $e_1, \ldots, e_N$ determines a cohomological orientation $\phi$, cf. [19] §20. Moreover, every Euler structure and every cohomological orientation can be obtained in this way. The Turaev torsion $\rho_{\varepsilon, \phi}(\alpha)$, corresponding to the pair $(\varepsilon, \phi)$, is, by definition, [11] §6, equal to the element $\sigma(\alpha)$ defined in (3.5). In particular, it is a non-vanishing holomorphic section of $\Det$, according to Definition 3.4. Since the Turaev torsion is independent of the choice of the CW-decomposition of $M$ [21][11], so is the holomorphic structure defined in Definition 3.4.

3.6. The acyclic case. If the representation $\alpha$ is acyclic, i.e., $H^\bullet(M, E_\alpha) = 0$, then the determinant line $\Det(H^\bullet(M, E_\alpha))$ is canonically isomorphic to $\mathbb{C}$. Hence, the Turaev torsion can be viewed as a complex-valued function on the set $\Rep_0(\pi_1(M), \mathbb{C}^n) \subset \Rep(\pi_1(M), \mathbb{C}^n)$ of acyclic representations. It is easy to see, cf. Th. 4.3 of [17], that this function is holomorphic on $\Rep_0(\pi_1(M), \mathbb{C}^n)$. (Moreover, it is a rational function on $\Rep(\pi_1(M), \mathbb{C}^n)$, all whose poles are in $\Rep(\pi_1(M), \mathbb{C}^n) \setminus \Rep_0(\pi_1(M), \mathbb{C}^n)$). In particular, the holomorphic structure on $\Det$, which we defined above, coincides, when restricted to $\Rep_0(\pi_1(M), \mathbb{C}^n)$, with the natural holomorphic structure obtained from the canonical isomorphism $\Det|_{\Rep_0(\pi_1(M), \mathbb{C}^n)} \simeq \Rep_0(\pi_1(M), \mathbb{C}^n) \times \mathbb{C}$.

We summarize the results of this section in the following

**Proposition 3.7.**

a. The holomorphic structure defined in Definition 3.4 is independent of any choices made.

b. For every Euler structure $\varepsilon$ and every cohomological orientation $\phi$, the Turaev torsion $\rho_{\varepsilon, \phi}(\alpha)$ is a holomorphic section of the determinant line bundle $\Det$.

c. The restriction of $\rho_{\varepsilon, \phi}(\alpha)$ to the open subset $\Rep_0(\pi_1(M), \mathbb{C}^n) \subset \Rep(\pi_1(M), \mathbb{C}^n)$ of acyclic representations is a holomorphic function.
4. Refined Analytic Torsion as a Holomorphic Section

One of the main results of this paper is that the refined analytic torsion $\rho_{an}$ is a non-vanishing holomorphic section of $\mathcal{D}et$. More precisely, the following theorem holds.

**Theorem 4.1.** The refined analytic torsion $\rho_{an}$ is a holomorphic section of the determinant bundle $\mathcal{D}et$, i.e., for any Euler structure $\varepsilon$ and any cohomological orientation $\sigma$, the ratio $\rho_{an}/\rho_{\varepsilon, \sigma}$ is a holomorphic function on $\text{Rep}(\pi_1(M), \mathbb{C}^n)$.

In particular, the restriction of $\rho_{an}$ to the set $\text{Rep}_0(\pi_1(M), \mathbb{C}^n)$ of acyclic representations, viewed as a complex-valued function via the canonical isomorphism

$$\mathcal{D}et|_{\text{Rep}_0(\pi_1(M), \mathbb{C}^n)} \simeq \text{Rep}_0(\pi_1(M), \mathbb{C}^n) \times \mathbb{C},$$

is a holomorphic function on $\text{Rep}_0(\pi_1(M), \mathbb{C}^n)$.

We prove this theorem in two steps: in this section we show that $\rho_{an}$ is holomorphic on $\text{Rep}(\pi_1(M), \mathbb{C}^n) \setminus \Sigma(M)$, where $\Sigma(M)$ is the set of singular points of the complex analytic set $\text{Rep}(\pi_1(M), \mathbb{C}^n)$. In the next section we will use this result to calculate the ratio of the refined analytic and the Turaev torsions. This calculation and the fact that the Turaev torsion is holomorphic, will imply that $\rho_{an}$ is holomorphic everywhere, cf. Subsection 5.13.

The main result of this section is the following

**Proposition 4.2.** Let $\alpha_0 \in \text{Rep}(\pi_1(M), \mathbb{C}^n) \setminus \Sigma(M)$. Then the refined analytic torsion $\rho_{an}$, viewed as a section of $\mathcal{D}et$, is holomorphic in a neighborhood of $\alpha_0$ with respect to the holomorphic structure defined in Section 3.

For convenience of the reader and in order to illustrate the main ideas of the proof we, first, prove the proposition for the case when $\alpha_0$ is acyclic. Then in a neighborhood of $\alpha_0$ the refined analytic torsion can be viewed as a complex-valued function, and we shall show that this function is holomorphic at $\alpha_0$.

4.3. Reduction to a finite dimensional complex. Fix a Riemannian metric $g^M$ on $M$ and a number $\lambda \geq 0$ such that there are no eigenvalues of $\mathcal{B}(\nabla_{\alpha_0}, g^M)^2$ with absolute value equal to $\lambda$. Then there exists a neighborhood $U_\lambda \subset \text{Rep}_0(\pi_1(M), \mathbb{C}^n) \setminus \Sigma(M)$ of $\alpha_0$ such that the same property holds for all $\alpha \in U_\lambda$. By Proposition 13.2 of [3] the function $\alpha \mapsto \text{Det}_{gr\theta}(\mathcal{B}_{even}^{(\lambda, \infty)}(\nabla_{\alpha}, g^M))$ is holomorphic$^4$ on $U_\lambda$. It follows now from (2.13) and (2.14) that to prove Proposition 4.2 it is enough to show that the function

$$\alpha \mapsto \rho_{[0, \lambda]}(\nabla_{\alpha}) = \rho_{[0, \lambda]}(\nabla_{\alpha}, g^M)$$

is holomorphic.

$^4$Proposition 13.2 of [3] only deals with the case where $\mathcal{B}$ is invertible and $\lambda = 0$. But the same proof works without any changes in our more general situation.
4.4. Reduction to one-parameter families of representations. By Hartog’s theorem, [14] Th. 2.2.8, it is enough to show that for every holomorphic curve \( \gamma : \mathcal{O} \to U_\lambda \), where \( \mathcal{O} \) is a connected open neighborhood of 0 in \( \mathbb{C} \), such that \( \gamma(0) = \alpha_0 \),

\[
z \mapsto \rho_{\gamma(0)}(\nabla z) = \nabla z, \quad z \in \mathcal{O},
\]

is a holomorphic function on \( \mathcal{O} \).

4.5. A family of connections. Let us introduce some additional notations. Let \( E \) be a vector bundle over \( M \) and let \( \nabla \) be a flat connection on \( E \). Fix a base point \( x_s \in M \) and let \( E_{x_s} \) denote the fiber of \( E \) over \( x_s \). We will identify \( E_{x_s} \) with \( \mathbb{C}^n \) and \( \pi_1(M, x_s) \) with \( \pi_1(M) \).

For a closed path \( p : [0, 1] \to M \) with \( p(0) = p(1) = x_s \), we denote by \( \text{Mon}_\nabla(p) \in \text{End} E_{x_s} \cong \text{Mat}_{n \times n}(\mathbb{C}) \) the monodromy of \( \nabla \) along \( p \). Since the connection \( \nabla \) is flat, \( \text{Mon}_\nabla(p) \) depends only on the class \([p]\) of \( p \) in \( \pi_1(M) \). Hence, the map \( p \mapsto \text{Mon}_\nabla(p) \) defines an element of \( \text{Rep}(\pi_1(M), \mathbb{C}^n) \), called the monodromy representation of \( \nabla \).

Suppose now that \( \mathcal{O} \subset \mathbb{C} \) is a connected open set. Let \( \gamma : \mathcal{O} \to \text{Rep}(\pi_1(M), \mathbb{C}^n) \) be a holomorphic curve. By Proposition 4.5 of [13], all the bundles \( E_{\gamma(z)}, z \in \mathcal{O} \), are isomorphic to each other. In other words, there exists a vector bundle \( E \to M \) and a family of flat connections \( \nabla_z, z \in \mathcal{O}, \) on \( E \), such that the monodromy representation of \( \nabla_z \) is equal to \( \gamma(z) \) for all \( z \in \mathcal{O} \). Moreover, Lemma B.6 of [3] shows that, for any \( z_0 \in \mathcal{O} \), the family \( \nabla_z \) can be chosen so that there exists a one-form \( \omega \in \Omega^1(M, \text{End} E) \) such that

\[
\nabla_z = \nabla_{z_0} + (z - z_0) \omega + o(z - z_0). \tag{4.1}
\]

Since \( z_0 \in \mathcal{O} \) is arbitrary, it follows now from the discussion in Subsection 4.4 that to finish the proof of Proposition 4.2 we only need to show that the function

\[
f(z) := \rho_{\gamma(0)}(\nabla_z, g^M)
\]

is complex differentiable at \( z_0 \), i.e., there exists \( a \in \mathbb{C} \), such that

\[
f(z) = f(z_0) + (z - z_0) a + o(z - z_0).
\]

4.6. Choice of a basis. Let \( \Pi_{[0, \lambda]}(z) \) \((z \in \mathcal{O})\) denote the spectral projection of the operator \( \mathcal{B}(\nabla z, g^M)^2 \), corresponding to the set of eigenvalues of \( \mathcal{B}(\nabla z, g^M)^2 \), whose absolute value is \( \leq \lambda \), cf. Subsection 4.3. It follows from (4.1) that there exists a bounded operator \( P : \Omega^*(M, E) \to \Omega^*(M, E) \) such that

\[
\Pi_{[0, \lambda]}(z) = \Pi_{[0, \lambda]}(z_0) + (z - z_0) P + o(z - z_0). \tag{4.3}
\]

We denote by \( \Omega^*(z) \) the image of \( \Pi_{[0, \lambda]}(z) \). For each \( j = 0, \ldots, r - 1 \), fix a basis \( w_j = \{w^1_j, \ldots, w^{m_j}_j\} \) of \( \Omega^j(z_0) \) and set \( w_{d-j} := \{\Gamma w^1_j, \ldots, \Gamma w^{m_j}_j\} \). To simplify the notation we will write \( w_{d-j} = \Gamma w_j \). Then \( w_j \) is a basis for \( \Omega^j(z_0) \) for all \( j = 0, \ldots, d \).

For each \( z \in \mathcal{O} \), \( j = 0, \ldots, d \), set

\[
w_j(z) = \{w^1_j(z), \ldots, w^{m_j}_j(z)\} := \{\Pi_{[0, \lambda]}(z) w^1_j, \ldots, \Pi_{[0, \lambda]}(z) w^{m_j}_j\}.
\]
It follows from the definition of $U_\lambda$ that the projection $\Pi_{[0, \lambda]}(z)$ depends continuously on $z$. Hence, there exists a neighborhood $\mathcal{O}' \subset \mathcal{O}$ of $z_0$, such that $w_j(z)$ is a basis of $\Omega^j(z)$ for all $z \in \mathcal{O}'$, $j = 0, \ldots, d$. Further, since $\Pi_{[0, \lambda]}(z)$ commutes with $\Gamma$, we obtain
\[
\mathbf{w}_{d-j}(z) = \Gamma \mathbf{w}_j(z). \tag{4.4}
\]
Clearly, $\mathbf{w}_j(z_0) = \mathbf{w}_j$ for all $j = 0, \ldots, d$.

Let
\[
\phi_{\Omega^*(z)} : \text{Det}(\Omega^*(z)) \rightarrow \text{Det}(H^*(M, E_{\gamma}(z))) \simeq \mathbb{C}
\]
denote the isomorphism [22]. For $z \in \mathcal{O}'$, let $w(z) \in \text{Det}(\Omega^*(z))$ be the element determined by the basis $\mathbf{w}_1(z), \ldots, \mathbf{w}_d(z)$ of $\Omega^*(z)$. More precisely, we introduce
\[
w_j(z) = w_j^1(z) \wedge \cdots \wedge w_j^{m_j}(z) \in \text{Det}(\Omega^j(z)),
\]
and set
\[
w(z) := w_0(z) \otimes w_1(z)^{-1} \otimes \cdots \otimes w_d(z)^{-1}.
\]
Then, according to Definition 2.3 it follows from (4.4) that, for all $z \in \mathcal{O}'$, the refined torsion of the complex $\Omega^*(z)$ is equal to $\phi_{\Omega^*(z)}(w(z))$, i.e.,
\[
\rho_{[0, \lambda]}(\nabla_z) = \phi_{\Omega^*(z)}(w(z)). \tag{4.5}
\]

4.7. Reduction to a Family of Differentials. For each $z \in \mathcal{O}'$, the space $\Omega^*(z)$ is a subcomplex of $(\Omega^*(M, E), \nabla_z)$, whose cohomology is canonically isomorphic to the cohomology of $(\Omega^*(M, E), \nabla_z)$ and, hence, to $H^*(M, E_{\gamma}(z))$. Using the basis $\mathbf{w}_j(z)$ we define the isomorphism
\[
\psi_j(z) : \mathbb{C}^{m_j} \rightarrow \Omega_{[0, \lambda]}^j(z)
\]
by the formula
\[
\psi_j(z)(x_1, \ldots, x_{m_j}) := \sum_{k=1}^{m_j} x_j \mathbf{w}_j^k(z) = \sum_{k=1}^{m_j} x_j \Pi_{[0, \lambda]}^j(z) \mathbf{w}_j^k.
\tag{4.6}
\]
We conclude that for each $z \in \mathcal{O}'$, the complex $(\Omega^*(z), \nabla_z)$ is isomorphic to the complex
\[
(W^*, d(z)) : \quad 0 \rightarrow \mathbb{C}^{m_0} \xrightarrow{d_0(z)} \mathbb{C}^{m_1} \xrightarrow{d_1(z)} \cdots \xrightarrow{d_{d-1}(z)} \mathbb{C}^{m_d} \rightarrow 0, \tag{4.7}
\]
where
\[
d_j(z) := \psi_{j+1}(z)^{-1} \circ \nabla_z \circ \psi_j(z), \quad j = 0, \ldots, d. \tag{4.8}
\]
It follows from (4.3) and (4.6) that $d_j(z)$ is complex differentiable at $z_0$, i.e., there exists a $(m_{j+1} \times m_j)$-matrix $A$ such that
\[
d_j(z) = d_j(z_0) + (z - z_0) A + o(z - z_0).
\]
Let $\psi(z) := \bigoplus_{j=0}^d \psi_j(z)$. Since $\Gamma(\Omega^j(z)) = \Omega^{d-j}(z)$ ($j = 0, \ldots, d$), we conclude that $m_j = m_{d-j}$. From (4.3) we obtain that
\[
\tilde{\Gamma} := \psi^{-1}(z) \circ \Gamma \circ \psi(z) \tag{4.9}
\]
is independent of $z \in \mathcal{O}'$ and
\[
\tilde{\Gamma} : (x_1, \ldots, x_{m_j}) \mapsto (x_1, \ldots, x_{m_j}), \quad j = 0, \ldots, d. \tag{4.10}
\]
It follows from (4.8) and (4.9) that
\[ \rho(z) = \rho_{\Gamma(z)}(\nabla z), \]  
where \( \rho(z) \) denotes the refined torsion of the finite dimensional complex \((W^*, d(z))\) corresponding to the chirality operator \( \Gamma \), cf. Definition 2.3.

Let \( \phi_{W^*}(z) : \text{Det}(W^*) \to \text{Det}(H^*(d(z))) \) denote the isomorphism (2.2). The standard bases of \( \mathbb{C}^{m_j} \) (\( j = 0, \ldots, d \)) define an element \( \tilde{w} \in \text{Det}(W^*) \). From (4.10) and the definition (2.5) of \( \rho_{\Gamma}(z) \) we conclude that
\[ \rho_{\Gamma}(z) = \phi_{W^*}(z)(\tilde{w}). \]  

Hence, to finish the proof of Proposition 4.2 in the case when \( \alpha_0 \) is acyclic it remains to show that the function \( z \mapsto \phi_{W^*}(z)(\tilde{w}) \) is complex differentiable at \( z_0 \). In view of (4.8), this follows from the following

**Lemma 4.8.** Let
\[ (C^*, \partial(z)) : 0 \to C^{n-k_0} \to C^{n-k_1} \to \cdots \to C^{n-k_d} \to 0, \]  
be a family of acyclic complexes defined for all \( z \) in an open set \( \mathcal{O} \subset \mathbb{C} \). Suppose that the differentials \( \partial_j(z) \) are complex differentiable at \( z_0 \in \mathcal{O} \). Then for any \( c \in \text{Det}(C^*) \) the function \( z \mapsto \phi_{(C^*, \partial(z))}(c) \) is complex differentiable at \( z_0 \).

**Proof.** It is enough to prove the lemma for one particular choice of \( c \). To make such a choice let us fix for each \( j = 0, \ldots, d \) a complement of \( \text{Im}(\partial_{j-1}(z_0)) \) in \( C^j \) and a basis \( v^1_j, \ldots, v^l_j \) of this complement. Since the complex \( C^* \) is acyclic, for all \( j = 0, \ldots, d \), the vectors
\[ \partial_{j-1}(z_0) v^1_{j-1}, \ldots, \partial_{j-1}(z_0) v^l_{j-1}, v^1_j, \ldots, v^l_j \]  
form a basis of \( C^j \). Let \( c \in \text{Det}(C^*) \) be the element defined by these bases. Then, for all \( z \) close enough to \( z_0 \) and for all \( j = 0, \ldots, d \),
\[ \partial_{j-1}(z) v^1_{j-1}, \ldots, \partial_{j-1}(z) v^l_{j-1}, v^1_j, \ldots, v^l_j \]  
is also a basis of \( C^j \). Let \( A_j(z) \) (\( j = 0, \ldots, d \)) denote the non-degenerate matrix transforming the basis (4.15) to the basis (4.14). Then, by the definition of the isomorphism \( \phi_{(C^*, \partial(z))} \), cf. §2.4 of [4],
\[ \phi_{(C^*, \partial(z))}(c) = (-1)^{\mathcal{N}(C^*)} \prod_{j=0}^{d} \text{Det}(A(z))^{(-1)^j}, \]  
where \( \mathcal{N}(C^*) \) is the integer defined in formula (2.15) of [4] which is independent of \( z \). Clearly, the matrix valued functions \( A_j(z) \) and, hence, their determinants are complex differentiable at \( z_0 \). Thus, so is the function \( z \mapsto \phi_{(C^*, \partial(z))}(c) \). \( \square \)
4.9. **Sketch of the proof in the non-acyclic case.** Let $\nabla_z$ be the family of connections \([4.11]\). To proof Proposition \([4.2]\) in the case when $\alpha_0$ is not acyclic it is enough to show that the function

$$f(z) := \frac{\rho_{\lambda}(\nabla_z, g^M)}{\rho_{\alpha}(\gamma(z))}$$

is complex differentiable at $z_0$. To see this we consider the integration map

$$J_z : \Omega^*(z) \subset \Omega^*(M, E) \to \mathbb{C}(K, \gamma(z)),$$

where $\mathbb{C}(K, \gamma(z))$ is the cochain complex corresponding to the CW-decomposition $K = \{e_1, \ldots, e_N\}$, cf. Subsection \([3.2]\). Note that the integration of $E$-valued differential forms is defined using a trivialization of $E$ over each cell $e_j$, and, hence, it depends on the flat connection $\nabla_z$, cf. below. We then consider the cone complex $\text{Cone}^\bullet(J_z)$ of the map $J_z$. This is a finite dimensional acyclic complex with a fixed basis, obtained from the bases of $\Omega^*(z)$ and $\mathbb{C}(K, \gamma(z))$. The torsion of this complex is equal to $f(z)$. An application of Lemma \([4.8]\) to this complex proves Proposition \([4.2]\).

In the definition of the integration map $J_z$ we have to take into account the fact that the vector bundles $E_{\gamma(z)}$ and $E$ are isomorphic but not equal. The standard integration map, cf. Subsection \([4.10]\), is a map from $\Omega^*(M, E)$ to the cochain complex $\mathbb{C}(K, E)$ of $K$ with coefficients in $E$, which is not equal to the complex $\mathbb{C}(M, E_{\gamma(z)})$. There is a natural isomorphism between the complexes $\mathbb{C}(K, E)$ and $\mathbb{C}(K, \gamma(z))$ which depends on $z$. The study of this isomorphism, which is conducted in Subsection \([4.11]\), is important for the understanding of the properties of $J_z$. In particular, it is used to show that $J_z$ is complex differentiable at $z_0$, which implies that the cone complex $\text{Cone}^\bullet(J_z)$ satisfies the conditions of Lemma \([4.8]\).

4.10. **The cochain complex of the bundle $E$.** Fix a CW-decomposition $K = \{e_1, \ldots, e_N\}$ of $M$. For each $j = 1, \ldots, N$ choose a point $x_j \in e_j$ and let $E_{x_j}$ denote the fiber of $E$ over $x_j$. The cochain complex of the CW-decomposition $K$ with coefficients in the flat bundle $(E, \nabla_z)$ can be identified with the complex $(\mathbb{C}(K, E), \partial_j^\prime)$

$$0 \to \bigoplus_{\dim e_i = 0} E_{x_i} \xrightarrow{\partial_0^\prime(z)} \bigoplus_{\dim e_i = 1} E_{x_i} \xrightarrow{\partial_1^\prime(z)} \cdots \xrightarrow{\partial_{d-1}^\prime(z)} \bigoplus_{\dim e_i = d} E_{x_i} \to 0.$$ (4.18)

We use the prime in the notation of the differentials $\partial_j^\prime$ in order to distinguish them from the differentials of the cochain complex $\mathbb{C}(K, \gamma(z))$ defined in \([3.3]\).

It follows from \([4.11]\) that $\partial_j^\prime(z)$ are complex differentiable at $z_0$, i.e., there exist linear maps

$$a_j : \bigoplus_{\dim e_i = j} E_{x_i} \to \bigoplus_{\dim e_i = j+1} E_{x_i}$$

such that

$$\partial_j^\prime(z) = \partial_j^\prime(z_0) + (z - z_0) a_j + o(z - z_0), \quad j = 1, \ldots, d - 1.$$
4.11. **Relationship with the complex $C^*(K, \gamma(z))$.** Recall that for each $z \in \mathcal{O}'$ the monodromy representation of $\nabla_z$ is equal to $\gamma(z)$. Let $\pi : \tilde{M} \to M$ denote the universal cover of $M$ and let $\tilde{E} = \pi^* E$ denote the pull-back of the bundle $E$ to $\tilde{M}$. Recall that in Subsection 4.5 we fixed a point $x_s \in M$. Let $\tilde{x}_s \in \tilde{M}$ be a lift of $x_s$ to $\tilde{M}$ and fix a basis of the fiber $\tilde{E}_{\tilde{x}_s}$ of $\tilde{E}$ over $x_s$. Then, for each $z \in \mathcal{O}'$, the flat connection $\nabla_z$ identifies $\tilde{E}$ with the product $\tilde{M} \times \mathbb{C}^n$. Let $\tilde{e}_j$ ($j = 1, \ldots, N$) be the lift of the cell $e_j$ fixed in Subsection 4.5 and let $\tilde{x}_j \in \tilde{e}_j$ be the lift of $x_j \in e_j$. Then the trivialization of $\tilde{E}$ defines isomorphisms

$$ S_{z,j} : E_{x_j} \simeq \tilde{E}_{\tilde{x}_j} \to \mathbb{C}^n, \quad j = 1, \ldots, N, \ z \in \mathcal{O}'. $$

The isomorphisms $S_{z,j}$ depend on the trivialization of $\tilde{E}$, i.e., on the connection $\nabla_z$. The direct sum $S_z = \bigoplus_j S_{z,j}$ is an isomorphism $S_z : C^*(K, E) \to C^*(K, \gamma(z))$ between the complex (4.18) and (4.3). It follows from (4.11) that $S_z$ is complex differentiable at $z_0$, i.e., there exists a linear map $s : C^*(K, E) \to \mathbb{C}^{n \cdot N}$ such that

$$ S_z = S_{z_0} + (z - z_0)s + o(z - z_0). $$

4.12. **The integration map.** For each $z \in \mathcal{O}'$ and for each $j = 1, \ldots, N$, the flat connection $\nabla_z$ defines an isomorphism $T_{j,z} : E|_{e_j} \to E_{\tilde{x}_j} \times e_j$. Thus, we can define the **integration map**

$$ I_z : \Omega^*(M, E) \to C^*(K, E) \tag{4.19} $$

by the formula

$$ I_z(\omega) = \bigoplus_{1 \leq j \leq N} \int_{e_j} T_{j,z}(\omega). \tag{4.20} $$

By the de Rham theorem, $I_z$ is a morphism of complexes, i.e., $I_z \circ \nabla_z = \partial(z) \circ I_z$, which induces an isomorphism of cohomology. Also it follows from (4.11) that $I_z$ is complex differentiable at $z_0$.

Finally, we consider the morphism of complexes

$$ J_z := S_z \circ I_z \circ \psi(z) : W^* \to C^*, \quad z \in \mathcal{O}'. \tag{4.21} $$

This map is complex differentiable at $z_0$ and induces an isomorphism of cohomology.

4.13. **The cone complex.** The cone complex $\text{Cone}^*(J_z)$ of the map $J_z$ is given by the sequence of vector spaces

$$ \text{Cone}^j(J_z) := W^j \oplus C^{j-1}(K, \gamma(z)) \simeq \mathbb{C}^{m_j} \oplus \mathbb{C}^{n \cdot k_j - 1}, \quad j = 0, \ldots, d, $$

with differentials

$$ \partial_j(z) = \begin{pmatrix} d_j(z) & 0 \\ J_{z,j} & \partial(\gamma(z)) \end{pmatrix}, $$

where $J_{z,j}$ denotes the restriction of $J_z$ to $W^j$. This is a family of acyclic complexes with differentials $\partial_j(z)$, which are complex differentiable at $z_0$. The standard bases of $\mathbb{C}^{m_j} \oplus \mathbb{C}^{n \cdot k_j - 1}$ define an element $c \in \text{Det}(\text{Cone}^*(J_z))$ which is independent of $z \in \mathcal{O}'$. Using the isomorphism (2.2), we hence obtain for each $z \in \mathcal{O}'$ the number $\varphi_{\text{Cone}^*(J_z)}(c) \in \mathbb{C} \setminus \{0\}$. From the discussion in Subsection 4.9 it follows that this number is equal to the ratio (4.2). Hence, to finish the
proof of the Proposition it remains to show that the function \( z \mapsto \phi_{\text{Cone}^*}(J_z)(c) \) is complex differentiable at \( z_0 \). This follows immediately from Lemma.

5. Comparison between the Refined Analytic and the Turaev Torsions

In this section we calculate the ratio of the refined analytic and the Turaev torsion. As a corollary, we conclude that the refined analytic torsion is a holomorphic section on the whole space \( \text{Rep}(\pi_1(M), \mathbb{C}^n) \) and not only on the subset \( \text{Rep}(\pi_1(M), \mathbb{C}^n) \setminus \Sigma(M) \) of smooth points.

First, we need to introduce some additional notations.

5.1. The \( \eta \)-invariant. First, we recall the definition of the \( \eta \)-function of a non-self-adjoint elliptic operator \( D \), cf. [12]. Let \( D : C^\infty(M, E) \to C^\infty(M, E) \) be an elliptic differential operator of order \( m \geq 1 \) with self-adjoint leading symbol. Assume that \( \theta \) is an Agmon angle for \( D \) (cf., for example, Definition 3.3 of [3]). Let \( \Pi_> \) (resp. \( \Pi_< \)) be a pseudo-differential projection whose image contains the span of all generalized eigenvectors of \( D \) corresponding to eigenvalues \( \lambda \) with \( \text{Re} \lambda > 0 \) (resp. with \( \text{Re} \lambda < 0 \)) and whose kernel contains the span of all generalized eigenvectors of \( D \) corresponding to eigenvalues \( \lambda \) with \( \text{Re} \lambda \leq 0 \) (resp. with \( \text{Re} \lambda \geq 0 \)). For all complex \( s \) with \( \text{Re} s < -d/m \), we define the \( \eta \)-function of \( D \) by the formula

\[
\eta_\theta(s, D) = \zeta_\theta(s, \Pi_>, D) - \zeta_\theta(s, \Pi_<, -D),
\]

where \( \zeta_\theta(s, \Pi_>, D) := \text{Tr}(\Pi_> D^s) \) and, similarly, \( \zeta_\theta(s, \Pi_<, D) := \text{Tr}(\Pi_< D^s) \). Note that, by definition, the purely imaginary eigenvalues of \( D \) do not contribute to \( \eta_\theta(s, D) \).

It was shown by Gilkey, [12], that \( \eta_\theta(s, D) \) has a meromorphic extension to the whole complex plane \( \mathbb{C} \) with isolated simple poles, and that it is regular at 0. Moreover, the number \( \eta_\theta(0, D) \) is independent of the Agmon angle \( \theta \).

Since the leading symbol of \( D \) is self-adjoint, the angles \( \pm \pi/2 \) are principal angles for \( D \). Hence, there are at most finitely many eigenvalues of \( D \) on the imaginary axis. Let \( m_+(D) \) (resp., \( m_-(D) \)) denote the number of eigenvalues of \( D \), counted with their algebraic multiplicities, on the positive (resp., negative) part of the imaginary axis. Let \( m_0(D) \) denote the algebraic multiplicity of 0 as an eigenvalue of \( D \).

**Definition 5.2.** The \( \eta \)-invariant \( \eta(D) \) of \( D \) is defined by the formula

\[
\eta(D) = \frac{\eta_\theta(0, D) + m_+(D) - m_-(D) + m_0(D)}{2}.
\]

As \( \eta_\theta(0, D) \) is independent of the choice of the Agmon angle \( \theta \) for \( D \), cf. [12], so is \( \eta(D) \).

**Remark 5.3.** Note that our definition of \( \eta(D) \) is slightly different from the one proposed by Gilkey in [12]. In fact, in our notation, Gilkey’s \( \eta \)-invariant is given by \( \eta(D) + m_-(D) \). Hence, reduced modulo integers, the two definitions coincide. However, the number \( e^{i\pi\eta(D)} \) will be multiplied by \((-1)^{m_-(D)}\) if we replace one definition by the other. In this sense, Definition 5.2 can be viewed as a sign refinement of the definition given in [12].
Let $\alpha \in \text{Rep}(\pi_1(M), \mathbb{C}^n)$ be a representation of the fundamental group of $M$ and let $E_\alpha \to M$ be the vector bundle defined by $\alpha$, cf. Subsection 3.1. We denote by $\nabla_\alpha$ the flat connection on $E_\alpha$. Fix a Riemannian metric $g^M$ on $M$ and denote by

$$\eta_\alpha = \eta(B_{\text{even}}(\nabla_\alpha, g^M)) \quad (5.3)$$

the $\eta$-invariant of the corresponding odd signature operator $B(\nabla_\alpha, g^M)$, cf. Definition 2.5.

5.4. The number $r_C$. For every integer homology class $\xi \in H_1(M, \mathbb{Z})$ and every $\alpha \in \text{Rep}(\pi_1(M), \mathbb{C}^n)$, we denote by $\det \alpha(\xi)$ the determinant of the value of $\alpha$ on any closed curve $\gamma$ representing $\xi$, $[\gamma] = \xi$.

Let $L_{d-1}(p) \in H^{d-1}(M, \mathbb{Z})$ denote the component in dimension $d - 1$ of the Hirzebruch $L$-polynomial $L(p)$ in the Pontrjagin classes of $M$ and let $\hat{L}_1 \in H_1(M, \mathbb{Z})$ denote the Poincaré dual of $L_{d-1}(p)$.

Lemma 5.5. The function

$$\alpha \mapsto r(\alpha) := \big| \det \alpha(\hat{L}_1) \big|^{1/2} \cdot e^{\pi \text{Im} \eta_\alpha} \in \mathbb{R}_+ \quad (5.4)$$

is locally constant on $\text{Rep}(\pi_1(M), \mathbb{C}^n)$. In particular, if $C \subset \text{Rep}(\pi_1(M), \mathbb{C}^n)$ is a connected component of $\text{Rep}(\pi_1(M), \mathbb{C}^n)$, which contains a unitary representation $\alpha_0$, then $\eta_{\alpha_0}$ is real and $|\det \alpha(\hat{L}_1)| = 1$, hence, $r(\alpha) = 1$ for all $\alpha \in C$.

Proof. Let $\text{Arg}_\alpha$ denote the unique cohomology class in $H^1(M, \mathbb{C}/\mathbb{Z})$ such that for every closed curve $\gamma \in M$ we have

$$\det \big( \alpha([\gamma]) \big) = \exp \left( 2\pi i \langle \text{Arg}_\alpha, [\gamma] \rangle \right), \quad (5.5)$$

where $\langle \cdot, \cdot \rangle$ denotes the natural pairing $H^1(M, \mathbb{C}/\mathbb{Z}) \times H_1(M, \mathbb{Z}) \to \mathbb{C}/\mathbb{Z}$. Then

$$\log r(\alpha) = \pi \text{Im} \big( \eta_\alpha - \langle \text{Arg}_\alpha, \hat{L}_1 \rangle \big).$$

Suppose $\alpha_t$ ($t \in [0, 1]$) is a smooth family of representations. From Theorem 12.3 and Lemma 12.6 of [3] we conclude that

$$\frac{d}{dt} \eta_{\alpha_t} = \frac{d}{dt} \langle \text{Arg}_{\alpha_t}, \hat{L}_1 \rangle.$$

Hence, $\frac{d}{dt} r(\alpha_t) = 0$. \qed

Definition 5.6. For each connected component $C \subset \text{Rep}(\pi_1(M), \mathbb{C}^n)$ we denote by $r_C$ the value of the function $r$ on $C$.

Lemma 5.5 implies that $r_C = 1$ if $C$ contains a unitary representation.

5.7. The homology class $\beta_\varepsilon$. We need the following

Lemma 5.8. Let $M$ be a closed oriented manifold of odd dimension $d = 2n - 1$. Let $L_{d-1}(p) \in H^{d-1}(M, \mathbb{Z})$ denote the component in dimension $d - 1$ of the Hirzebruch $L$-polynomial $L(p)$ in the Pontrjagin classes of $M$. Then the reduction of $L_{d-1}(p)$ modulo 2 is equal to the $(d - 1)$-Stiefel-Whitney class $w_{d-1}(M) \in H^{d-1}(M, \mathbb{Z}_2)$ of $M$. 
Proof. For any homology class $\xi \in H_{d-1}(M, \mathbb{Z})$ there exists a smooth oriented submanifold $X_{\xi} \subset M$, representing $\xi$. Then $\langle L_{d-1}(p), \xi \rangle$ is equal to the signature $\sigma(X_{\xi})$ of $X_{\xi}$. The parity of $\sigma(X_{\xi})$ is equal to the parity of the Euler characteristic $\chi(X_{\xi})$ of $X_{\xi}$, which, in turn, is equal to $\langle w_{d-1}(M), \xi \rangle = \langle w_{d-1}(X_{\xi}), \xi \rangle$. Thus we conclude that

$$\langle L_{d-1}(p) - w_{d-1}(M), \xi \rangle = 0 \mod 2,$$

for any homology class $\xi \in H_{d-1}(M, \mathbb{Z})$. \hfill $\square$

We denote by $\hat{L}_1 \in H_1(M, \mathbb{Z})$ the Poincaré dual of $L_{d-1}(p)$ and by $c(\varepsilon) \in H_1(M, \mathbb{Z})$ the characteristic class of the Euler structure $\varepsilon$, cf. \cite{11} or Section 5.2 of \cite{13}.

**Corollary 5.9.** The class $\hat{L}_1(p) + c(\varepsilon) \in H_1(M, \mathbb{Z})$ is divisible by 2, i.e. there exists a (not necessarily unique) homology class $\beta_\varepsilon \in H_1(M, \mathbb{Z})$ such that

$$-2 \beta_\varepsilon = \hat{L}_1(p) + c(\varepsilon).$$

(5.6)

**Proof.** It is shown on page 209 of \cite{13} that the reduction of $c(\varepsilon)$ modulo 2 is equal to the Poincaré dual of the Stiefel-Whitney class $w_{d-1}(M)$. Hence, it follows from Lemma 5.8 that the reduction of $\hat{L}_1(p) + c(\varepsilon)$ is a zero element of $H_1(M, \mathbb{Z}/2)$. \hfill $\square$

The equality (5.6) defines $\beta_\varepsilon$ modulo two-torsion elements in $H_1(M, \mathbb{Z})$. We fix a solution of (5.6) and for the rest of the paper $\beta_\varepsilon$ denotes this solution.

5.10. **Comparison between the Turaev and the refined analytic torsions.** One of the main results of this paper is the following extension of the Cheeger-Müller theorem about the equality between the Reidemeister and the Ray-Singer torsions:

**Theorem 5.11.** Suppose $M$ is a closed oriented odd dimensional manifold. Let $\varepsilon$ be an Euler structure on $M$ and let $\sigma$ be a cohomological orientation of $M$. Then, for each connected component $\mathcal{C}$ of $\text{Rep}(\pi_1(M), \mathbb{C}^n)$, there exists a constant $\theta^\mathcal{C} = \theta^\mathcal{C}_0 \in \mathbb{R}/2\pi\mathbb{Z}$, depending on $\sigma$ (but not on $\varepsilon$), such that

$$\theta^\mathcal{C}_\sigma \equiv \theta^\mathcal{C}_0 + n\pi, \mod 2\pi,$$

(5.7)

and for any representation $\alpha \in \mathcal{C},$

$$\frac{\rho_{\text{an}}(\alpha)}{\rho_{\varepsilon, \sigma}(\alpha)} = e^{i\theta^\mathcal{C}_0 \cdot r_C \cdot \det \alpha(\beta_\varepsilon)},$$

(5.8)

where $\beta_\varepsilon \in H_1(M, \mathbb{Z})$ is the homology class defined in (5.6) and $r_C > 0$ is defined in Definition 5.6. If the connected component $\mathcal{C}$ contains a unitary representation $\alpha_0$, then $r_C = 1$.

As an immediate corollary of Theorem 5.11 we obtain

**Corollary 5.12.** If the representations $\alpha_1, \alpha_2$ belong to the same connected component of $\text{Rep}(\pi_1(M), \mathbb{C}^n)$ then

$$\frac{\rho_{\text{an}}(\alpha_1)}{\rho_{\text{an}}(\alpha_2)} = \frac{\rho_{\varepsilon, \sigma}(\alpha_1)}{\rho_{\varepsilon, \sigma}(\alpha_2)} \frac{\det \alpha_1(\beta_\varepsilon)}{\det \alpha_2(\beta_\varepsilon)}.$$

(5.9)
5.13. **Proof of Theorem 5.11** Before proving Theorem 5.11 let us note that, since the right hand side of the equality (5.8) is obviously holomorphic in $\alpha$, it follows from this equality that $\rho_{an}(\alpha)$ is a holomorphic section of $\text{Det}$, cf. Definition 5.4. Hence, Theorem 4.1 is proven. □

5.14. **Proof of Theorem 5.11** In Subsection 5.15 below, we use the calculations of the Ray-Singer norm of the Turaev torsion from [11] and the calculation of the Ray-Singer norm of the refined analytic torsion from [4] to compute the absolute value of the left hand side of (5.8). More precisely we conclude that (cf. (5.16))

$$\left| \det \alpha(\beta_\varepsilon)^{-1} \cdot \frac{\rho_{an}(\alpha)}{\rho_{\varepsilon, o}(\alpha)} \right| = r_C.$$  

Similarly, (5.10)

$$\left| \det \alpha(\beta_\varepsilon)^{-1} \cdot \frac{\rho_{an}(\alpha)}{\rho_{\varepsilon, o}(\alpha)} \right| = r_C.$$  

By Proposition 4.2, $\rho_{an}(\alpha)/\rho_{\varepsilon, o}(\alpha)$ is an analytic function on the set $\text{Rep}(\pi_1(M), \mathbb{C}^n) \setminus \Sigma(M)$ of non-singular points of $\text{Rep}(\pi_1(M), \mathbb{C}^n)$. Further, $\det \alpha(\beta_\varepsilon)$ is obviously a polynomial function on $\text{Rep}(\pi_1(M), \mathbb{C}^n)$. Hence, the function

$$\alpha \mapsto \det \alpha(\beta_\varepsilon)^{-1} \cdot \frac{\rho_{an}(\alpha)}{\rho_{\varepsilon, o}(\alpha)}$$

is holomorphic on $\text{Rep}(\pi_1(M), \mathbb{C}^n) \setminus \Sigma(M)$. By (5.11) the absolute value of this function is locally constant $\text{Rep}(\pi_1(M), \mathbb{C}^n) \setminus \Sigma(M)$. It follows that the function itself is locally constant, i.e., there exists a locally constant real valued function $\theta_{\varepsilon, o} : \text{Rep}(\pi_1(M), \mathbb{C}^n) \setminus \Sigma(M) \to \mathbb{R}/2\pi \mathbb{Z}$ such that

$$\frac{\rho_{an}(\alpha)}{\rho_{\varepsilon, o}(\alpha)} = e^{i\theta_{\varepsilon, o}(\alpha)} \cdot r_C \cdot \det \alpha(\beta_\varepsilon), \quad \alpha \in \text{Rep}(\pi_1(M), \mathbb{C}^n) \setminus \Sigma(M).$$  

In Lemma 5.16 we show that the function $\rho_{an}(\alpha)/\rho_{\varepsilon, o}(\alpha)$ is continuous on $\text{Rep}(\pi_1(M), \mathbb{C}^n)$. Hence, $\theta_{\varepsilon, o}(\alpha)$ extends to a continuous function on $\text{Rep}(\pi_1(M), \mathbb{C}^n)$. Since $\theta_{\varepsilon, o}$ is locally constant on the open dense subset $\text{Rep}(\pi_1(M), \mathbb{C}^n) \setminus \Sigma(M)$, which has only finitely many connected components, it is also locally constant on $\text{Rep}(\pi_1(M), \mathbb{C}^n)$. In other words, $\theta_{\varepsilon, o}(\alpha)$ depends only on the connected component $C$ containing $\alpha$.

To finish the proof of Theorem 5.11 it remains to prove that $\theta_{\varepsilon, o}$ is independent of $\varepsilon$ and satisfies (5.7). This is done in Subsection 5.17.

5.15. **The Ray-Singer norm of the Turaev and the refined analytic torsions.** Let $\| \cdot \|_{\text{Det}(H^*(M, E_\alpha))}$ denote the Ray-Singer norm on the determinant line $\text{Det}(H^*(M, E_\alpha))$, cf. [17, 2, 11, 4], Theorem 10.2 of [11]. States that

$$\|\rho_{\varepsilon, o}(\alpha)\|_{\text{Det}(H^*(M, E_\alpha))} = \left| \det \alpha(\varepsilon) \right|^{1/2}. \quad (5.12)$$

Further, by Theorem 11.3 of our previous paper [4],

$$\|\rho_{an}\|_{\text{Det}(H^*(M, E_\alpha))} = e^{\pi \text{Im} \eta_\alpha}. \quad (5.13)$$

Combining (5.12) and (5.13) we obtain

$$\left| \frac{\rho_{an}(\alpha)}{\rho_{\varepsilon, o}(\alpha)} \right| = \left| \det \alpha(c(\varepsilon)) \right|^{-1/2} \cdot e^{\pi \text{Im} \eta_\alpha}. \quad (5.14)$$
Since for any two homology classes \( a, b \in H_1(M, \mathbb{Z}) \) we have \( \det \alpha(a + b) = \det \alpha(a) \cdot \det \alpha(b) \), in view of (5.16) we obtain
\[
| \det \alpha(c(\varepsilon)) | = | \det \alpha(c(\varepsilon) + \tilde{L}_1) | \cdot | \det \alpha(\tilde{L}_1) |^{-1} = | \det \alpha(\beta_\varepsilon) |^{-2} \cdot | \det \alpha(\tilde{L}_1) |^{-1}. \tag{5.15}
\]
Substituting (5.15) into (5.14) we obtain, using (5.4),
\[
\frac{\rho_{a, \varepsilon}(\alpha)}{\rho_{b, \varepsilon}(\alpha)} = | \det \alpha(\beta_\varepsilon) | \cdot \left( | \det \alpha(\tilde{L}_1) |^{1/2} \cdot e^{\pi \text{Im} \eta_\varepsilon} \right)
\]
\[
= | \det \alpha(\beta_\varepsilon) | \cdot r_C. \tag{5.16}
\]

**Lemma 5.16.** The function \( \alpha \mapsto \frac{\rho_{a, \varepsilon}(\alpha)}{\rho_{b, \varepsilon}(\alpha)} \) is continuous on \( \text{Rep}(\pi_1(M), \mathbb{C}^n) \).

**Proof.** The proof is similar (but easier) to the proof of Proposition 4.2. The only difference is that we now assume that \( \alpha_0 \in \text{Rep}(\pi_1(M), \mathbb{C}^n) \) is an arbitrary (possibly singular) point and that the connection \( \nabla_z \) depends merely continuously on \( z \). Correspondingly, throughout the proof, one should replace the words “complex differentiable” by “continuous”. \( \square \)

5.17. **Dependence of \( \theta_{\varepsilon, \rho} \) on the Euler structure and the cohomological orientation.**

From Lemma 5.16 we conclude that \( \theta_{\varepsilon, \rho} \) is locally constant on \( \text{Rep}(\pi_1(M), \mathbb{C}^n) \). For each connected component \( C \) of \( \text{Rep}(\pi_1(M), \mathbb{C}^n) \) denote by \( \theta^C_{\varepsilon, \rho} \) the value of \( \theta_{\varepsilon, \rho} \) on \( C \). To finish the proof of Theorem 5.11 it remains to show that \( \theta^C_{\varepsilon, \rho} \) is independent of \( \varepsilon \) and satisfies (5.7). In the case of acyclic representations the independence of \( \theta^C_{\varepsilon, \rho} \) of \( \varepsilon \) was first established by R.-Z. Huang [15].

Recall that the group \( H_1(M, \mathbb{Z}) \) acts freely and transitively on the set \( \text{Eul}(M) \) of all Euler structures on \( M \), cf. [21, 11]. Suppose \( \varepsilon_1, \varepsilon_2 \in \text{Eul}(M) \) are two Euler structures and let \( h \in H_1(M, \mathbb{Z}) \) be such that
\[
\varepsilon_2 = h + \varepsilon_1,
\]
where \( h + \varepsilon_1 \) denotes the action of \( h \) on \( \varepsilon_1 \). By formula (5.3) of [11]
\[
c(\varepsilon_2) = 2h + c(\varepsilon_1) \in H_1(M, \mathbb{Z}). \tag{5.17}
\]
Further, by the first displayed formula on page 211 of [11]
\[
\rho_{\varepsilon_2, \rho}(\alpha) = \det \alpha(h) \cdot \rho_{\varepsilon_1, \rho}(\alpha). \tag{5.18}
\]

Combining (5.17) and (5.18) with (5.6), we conclude that
\[
\frac{\det \alpha(\beta_2)}{\det \alpha(\beta_1)} = \det \alpha(\beta_2 - \beta_1) = \det \alpha(h)^{-1} \cdot \frac{\rho_{\varepsilon_1, \rho}(\alpha)}{\rho_{\varepsilon_2, \rho}(\alpha)}. \tag{5.19}
\]
Comparing (5.19) with (5.8) we conclude that \( \theta^C_{\varepsilon, \rho} \) is independent of \( \varepsilon \).

It is shown in §6.3 of [11] that
\[
\rho_{\varepsilon, \rho}(\alpha) = (-1)^n \rho_{\varepsilon, \rho}(\alpha). \tag{5.20}
\]
Comparing this equality with (5.8) we conclude that \( e^{i\theta^C_{\varepsilon, \rho}} = (-1)^n \cdot e^{i\theta^C_{\varepsilon, \rho}} \), which is equivalent to (5.7). The proof of Theorem 5.11 is now complete. \( \square \)
6. Application to the eta-invariant

As an application of Theorem 5.11, we establish a relationship between the $\eta$-invariant and the phase of the Turaev torsion which improves and generalizes a theorem of Farber [9] and an earlier result of ours, cf. Remark 6.5 below.

6.1. Phase of the Turaev torsion of a unitary representation. Recall that if $\alpha \in \text{Rep}(\pi_1(M), \mathbb{C}^n)$ is an acyclic representation, then we view the refined analytic torsion $\rho_{an}(\alpha)$ as a non-zero complex number, via the canonical isomorphism $\text{Det}(H^\bullet(M, E_\alpha)) \simeq \mathbb{C}$. We denote the phase of a complex number $z$ by $\text{Ph}(z) \in [0, 2\pi)$ so that $z = |z|e^{i\text{Ph}(z)}$.

**Proposition 6.2.** Suppose that $\alpha_1, \alpha_2 \in \text{Rep}(\pi_1(M), \mathbb{C}^n)$ are acyclic unitary representations which lie in the same connected component of $\text{Rep}(\pi_1(M), \mathbb{C}^n)$. Then, modulo $2\pi\mathbb{Z}$,

$$\text{Ph}(\rho_{\varepsilon, o}(\alpha_1)) + \pi \eta_{\alpha_1} + 2\pi \langle \text{Arg}_{\alpha_1}, \beta_{\varepsilon} \rangle \equiv \text{Ph}(\rho_{\varepsilon, o}(\alpha_2)) + \pi \eta_{\alpha_2} + 2\pi \langle \text{Arg}_{\alpha_2}, \beta_{\varepsilon} \rangle \ (6.1)$$

**Proof.** By formula (14.11) of [3], for any acyclic unitary representation $\alpha$ we have

$$\text{Ph}(\rho_{an}(\alpha)) = -\pi \eta_{\alpha} + \pi \frac{\text{rank} \alpha}{2} \int_N L(p) \mod 2\pi\mathbb{Z}, \ (6.2)$$

where $N$ is an oriented manifold whose oriented boundary is the disjoint union of two copies of $M$ and $L(p)$ is the Hirzebruch polynomial in Pontrjagin classes of $N$. Hence,

$$\text{Ph}(\rho_{an}(\alpha_1)) - \text{Ph}(\rho_{an}(\alpha_2)) = \pi (\eta_{\alpha_2} - \eta_{\alpha_1}) \mod 2\pi\mathbb{Z}, \ (6.3)$$

From (6.2) and (6.3) we obtain, mod $2\pi\mathbb{Z}$,

$$\text{Ph}(\rho_{an}(\alpha_1)) - \text{Ph}(\rho_{an}(\alpha_2)) \equiv \text{Ph}(\rho_{\varepsilon, o}(\alpha_1)) - \text{Ph}(\rho_{\varepsilon, o}(\alpha_2)) + 2\pi \langle \text{Arg}_{\alpha_1}, \beta_{\varepsilon} \rangle - 2\pi \langle \text{Arg}_{\alpha_2}, \beta_{\varepsilon} \rangle. \ (6.4)$$

Combining (6.3) with (6.4) we obtain (6.1). \hfill \Box

6.3. Sign of the absolute torsion. Suppose that the Stiefel-Whitney class

$$w_{d-1}(M) \in H^{d-1}(M, \mathbb{Z}_2)$$

vanishes (this is always the case when $\dim M \equiv 3$ (mod 4), cf. [16]). Then one can choose an Euler structure $\varepsilon$ such that $c(\varepsilon) = 0$, cf. [10] §3.2. Let $\alpha \in \text{Rep}(\pi_1(M), \mathbb{C}^n)$ be an acyclic representation. Assume that the first Stiefel-Whitney class $w_1(E_\alpha)$, viewed as a homomorphism $H_1(M, \mathbb{Z}) \to \mathbb{Z}_2$, vanishes on the 2-torsion subgroup of $H_1(M, \mathbb{Z})$. In this case there is also a canonical choice of the cohomological orientation $o$, cf. [10] §3.3. Then the Turaev torsion $\rho_{\varepsilon, o}(\alpha)$ corresponding to any $\varepsilon$ with $c(\varepsilon) = 0$ and the canonically chosen $o$ will be the same.

If the above assumptions on $w_{d-1}(M)$ and $w_1(E_\alpha)$ are satisfied, then the number

$$\rho_{\text{abs}}^{\varepsilon, o}(\alpha) := \rho_{\varepsilon, o}(\alpha) \in \mathbb{C}\setminus\{0\},$$

with $\varepsilon$ chosen so that $c(\varepsilon) = 0$, is canonically defined, i.e., is independent of any choices. It was introduced by Farber and Turaev, [10], who called it the absolute torsion. If $\alpha$ is an acyclic
unitary representation, then \( \rho^{\text{abs}}(\alpha) \in \mathbb{R} \), cf. Theorem 3.8 of \([10]\) and, hence,
\[
e^{i \text{Ph}(\rho^{\text{abs}}(\alpha))} = \text{sign} \left( \rho^{\text{abs}}(\alpha) \right).
\]
Note also, that since \( c(\varepsilon) = 0 \) it follows from \((6.5)\) that \( 2\beta_{\varepsilon} = -\hat{L}_1 \). Therefore,
\[
2\pi \left\langle \text{Arg}_\alpha, \beta_{\varepsilon} \right\rangle \equiv -\pi \left\langle \text{Arg}_\alpha, \hat{L}_1 \right\rangle, \mod 2\pi \mathbb{Z}. \tag{6.5}
\]
Recall that \( \hat{L}_1 \) vanishes if \( \dim M \equiv 3 \) (mod 4).

From Proposition \((6.2)\) and \((6.5)\) we now obtain the following

**Corollary 6.4.** Suppose that \( \alpha_1, \alpha_2 \in \text{Rep}(\pi_1(M), \mathbb{C}^n) \) are acyclic unitary representations which lie in the same connected component of \( \text{Rep}(\pi_1(M), \mathbb{C}^n) \). Suppose that he first Stiefel-Whitney class \( w_1(E_{\alpha_1}) = w_1(E_{\alpha_2}) \) vanishes on the 2-torsion subgroup of \( H_1(M, \mathbb{Z}) \).

(i) If \( \dim M \equiv 3 \) (mod 4), then
\[
\text{sign} \left( \rho^{\text{abs}}(\alpha_1) \right) \cdot e^{i\pi n_{\alpha_1}} = \text{sign} \left( \rho^{\text{abs}}(\alpha_2) \right) \cdot e^{i\pi n_{\alpha_2}}.
\]
(ii) If \( \dim M \equiv 1 \) (mod 4) and \( w_{d-1}(M) = 0 \), then
\[
\text{sign} \left( \rho^{\text{abs}}(\alpha_1) \right) \cdot e^{i\pi (n_{\alpha_1} - \langle \text{Arg}_\alpha, \hat{L}_1 \rangle)} = \text{sign} \left( \rho^{\text{abs}}(\alpha_2) \right) \cdot e^{i\pi (n_{\alpha_2} - \langle \text{Arg}_\alpha, \hat{L}_1 \rangle)}.
\]

**Remark 6.5.** For the special case when there is a real analytic path \( \alpha_t \) of unitary representations connecting \( \alpha_1 \) and \( \alpha_2 \) such that \( \alpha_t \) is acyclic for all but finitely many values of \( t \), Corollary \((6.4)\) was established by Farber, using a completely different method,\(^5\) see \([9]\), Theorems 2.1 and 3.1. In \([31] \) \S14.11] we succeeded in eliminating the assumption of the existence of a real analytic path \( \alpha_t \) and assumed only that the representations \( \alpha_1 \) and \( \alpha_2 \) lie in the same connected component of a certain subset of the set of acyclic representations. Corollary \((6.4)\) improves on this result by showing that it is enough to assume that \( \alpha_1 \) and \( \alpha_2 \) lie in the same connected component of \( \text{Rep}(\pi_1(M), \mathbb{C}^n) \).

\(^5\)Note that Farber’s definition of the \( \eta \)-invariant differs from ours by a factor of 2. Moreover, the sign in front of \( \langle \text{Arg}_{\alpha_1}, \hat{L}_1 \rangle \) in \([9]\) should be the opposite one.
