Choptuik’s critical spacetime exists

Michael Reiterer\textsuperscript{1}, Eugene Trubowitz\textsuperscript{1}
Department of Mathematics, ETH Zurich, Switzerland

Abstract: About twenty years ago, Choptuik studied numerically the gravitational collapse (Einstein field equations) of a massless scalar field in spherical symmetry, and found strong evidence for a universal, self-similar solution at the threshold of black hole formation. We prove rigorously the existence of a real analytic solution, that we interpret as the solution observed by Choptuik. Our construction covers an open neighborhood of the past light cone of the singularity. The proof is computer assisted. Starting from an explicit approximate solution, we show that nearby there is a true solution. The source code and a high precision data file (about 80 significant decimal digits, with rigorous error bounds) are included. We do not study perturbations.

1 Introduction

Figure 1: Scalar field $\phi$ for Choptuik’s spacetime.

\textsuperscript{1}Part of this work was carried out while the authors were visiting NYU Abu Dhabi, in fall 2011.
The Einstein field equations for a four-dimensional metric $g$ with signature $(-, +, +, +)$, coupled to a massless scalar field $\phi$, are $\text{Ricci}_g = 2 \, d\phi \otimes d\phi$ and $\Box_g \phi = 0$. If one imposes spherical symmetry on $g$ and $\phi$, the problem reduces to a two-dimensional problem. The self-similar solution $(g, \phi)$ that Choptuik [C] observed numerically, and whose existence we prove in this paper, has the nontrivial scalar field $\phi$ in Figure 1.

Figure 1 was generated from an approximation to the true solution, indistinguishable from the true solution at image resolution. Regions with $\phi < 0$ in blue, and with $\phi > 0$ in red, alternate. The contour lines are at $\phi = 0, \pm \frac{1}{2}, \pm 1, \pm \frac{3}{2}, \pm 2$. The self-similarity is captured by a diffeomorphism

$$\Theta : \text{Choptuik spacetime} \rightarrow \text{Choptuik spacetime}$$

that maps every blue (red) region to the next red (blue) region above it, $\phi \circ \Theta = -\phi$, and that rescales all lengths by a constant $e^{-K}$, equivalently $\Theta^* g = e^{-2K} g$. Here $K \approx 1.72$ and we prove

$$|K - 17227262011139106749857597278819186222103458805781088634788403570540271455648855 \cdot 10^{-80}| \leq 10^{-80}$$

consistent with the numerical result 3.445452402(3) for $2K$ in [MG2]. The very good review [GM] contains references to other numerical results.

![Figure 2: The $(u_-, u_+)$ plane. The shaded region is the domain of Figure 1. At the future singular point, the scalar curvature blows up. Note that the dashed line is actually closer to $u_- = 0$ than shown here.](image)

We have to specify the coordinates used to generate Figure 1. Every point in Figure 1 is a two-sphere. Lines at $\pm 45$ degrees are level sets of an ingoing or outgoing spherically symmetric null coordinate $u_-$ or $u_+$, respectively.
The key property that distinguishes the coordinates \( u_\pm \) is that \( \Theta \) is exactly a linear rescaling of Figures 1 and 2 about the singular point: There is a constant \( \mu > 0 \) such that \( u_\pm \circ \Theta = e^{-2\pi \mu} u_\pm \). This property, and Figure 2, determine \( u_\pm \) up to a multiplicative constant, see Section 1.4. The constant \( \mu \approx 0.168 \) is itself a geometric invariant of the Choptuik spacetime. We prove

\[
|\mu - 1683070789634499695101349790428574207210
0199080892966476395293134873313662587505 \cdot 10^{-80}| \leq 10^{-80} \tag{3}
\]

The critical light cone \( u_- = 0 \) plays a crucial role. For example, by causality, any initial data set for the Einstein-scalar-field system that coincides with Choptuik’s spacetime on a spacelike hypersurface \( \Sigma \) as in Figure 3 also contains the shaded region above it, and is singular. No such conclusion can be drawn for \( \Sigma' \). For this reason, it is essential to construct (an open neighborhood of) the past light cone of the singularity.

We prove that \( (g, \phi) \) is real analytic on the open domain bounded by the dashed line \( u_- = -u_+/81 > 0 \) (the value 81 has no special significance). This includes real analyticity across \( u_- = 0 \), a basic feature of Choptuik’s spacetime. We now state our result in a logically complete way.

**Main result.** Let \( M = \{(u_-, u_+) \in \mathbb{R}^2 \mid u_+ < 0, \ u_+ < u_- < -u_+/81\} \). There are constants \( K, \mu > 0 \) that satisfy (2) and (3), and real analytic functions \( \phi, \zeta, Q : M \to \mathbb{R} \), that satisfy

\[
\begin{align*}
\phi \circ \Theta &= -\phi \\
\zeta \circ \Theta &= \zeta + K \\
Q \circ \Theta &= Q \quad \text{with } \Theta : M \to M, \ (u_-, u_+) \mapsto e^{-2\pi \mu}(u_-, u_+)
\end{align*}
\]
such that on the four-dimensional manifold $M \times S^2$, one has $\mu + Q\xi^2 > 0$ with $\xi = \frac{u_+ - u_-}{u_+ + u_-}$, and the spherically symmetric Lorentzian metric

$$g = \exp(-2\zeta) \left( -\frac{2(du_- \otimes du_+ + du_+ \otimes du_-)}{\mu^2(u_+ + u_-)^2} + \frac{\xi^2}{(\mu + Q\xi^2)^2} g_{\text{standard} S^2} \right)$$

where $g_{\text{standard} S^2}$ is the metric on the unit sphere $S^2 \subset \mathbb{R}^3$, satisfies:

- $\Theta^* g = e^{-2K} g$, the spacetime is ‘discretely self-similar’. Here, $\Theta$ is extended trivially to a map $M \times S^2 \to M \times S^2$.

- $\text{Ricci}_g = 2d\phi \otimes d\phi$ and $\Box_g \phi = 0$.

- The scalar curvature $R_g = 2g^{-1}(d\phi, d\phi)$ is not identically zero. It satisfies $R_g \circ \Theta = e^{2K} R_g$ and is therefore unbounded.

- The boundary $u_+ = u_-$ is a removable standard polar coordinate singularity, because the functions $f = \phi, \zeta, Q$ extend real analytically by reflection,

$$f(u_-, u_+) = f(u_+, u_-)$$

- The solution is close to the high-precision data in the file RefAplusB.dat. For a quantitative statement, see equations (27), (44), (60). Also see (61).

We do not study perturbations about the Choptuik spacetime, that are relevant for many of the (conjectured) properties of the solution. Our paper can be the starting point for a rigorous investigation of this kind. This would be interesting, because current numerical results seem to be inconclusive, see [MG1] and [CHLP], and Sections 3.7 and 5.3 of [GM].

It has been shown for the Einstein-scalar field system in spherical symmetry that the solution disperses for sufficiently small initial data, and forms trapped spheres for sufficiently large initial data, see [Chr1], [Chr2], [Chr3]. Since we construct the solution through a contraction mapping, it would be possible to state not only an existence, but also a local uniqueness result of a technical kind. This would allow us to define the Choptuik spacetime as that unique solution. We have taken the freedom to refer to the Choptuik spacetime, even though we have not formally stated local uniqueness.

The rest of Section 1 are detailed (but informal) overviews:

Section 1.1: setup and analysis
Section 1.2: basic strategy
Section 1.3: role of the computer
Section 1.4: the invariant $\mu$ and the coordinates $(\tau, \xi)$
1.1 Overview – setup and analysis

We reduce the spherically symmetric four-dimensional problem to a two-dimensional problem, stated in Section 2.2. Contrary to the introduction, we do not use \( u_\pm \) as coordinates, and we do not use \( \phi, \zeta, Q \) as unknowns:

**Coordinates:** We use \((\tau, \xi)\) given by the change of coordinates

\[
u_\sigma = -(1 + \sigma \xi) \exp(-\mu \tau) \quad \sigma = \pm
\]

Note that \((\tau, \xi) \circ \Theta = (\tau + 2\pi, \xi)\), and one can use Fourier series.

**Unknowns:** A number \( \mu > 0 \) (see below) and \( \omega = (\omega_1, \omega_2, \omega_3, \omega_4) \) given by the change of variables (8). Advantage: The field equations become first order and quadratically nonlinear, a property that we consistently exploit. Each \( \omega_i \) is \( 2\pi \) periodic or antiperiodic in \( \tau \), all are \( 4\pi \) periodic.

**The role of \( \mu \):** For the analysis, \( \mu > 0 \) is not a constant, but an unknown on the same footing as the \( \omega_i \). This ‘gain’ of one degree of freedom is, in many respects, a compensation for the ‘loss’ of one degree of freedom due to translation invariance of the problem in \( \tau \). This becomes most explicit in (32).

Note that the ubiquitous, characteristic differential operators (14) are *quasilinear* but not semilinear, because they depend on the unknown \( \mu \). It seems that this ‘minimal’ quasilinearity cannot be removed from the problem – not without introducing a complication somewhere else. Fortunately, in the space of analytic functions that we work in, the quasilinearity plays a minor role. This becomes explicit in the boundedness of the operator in (37b).

We represent the \( \omega_i \) as combined Fourier-Chebyshev series:

**4\pi-Fourier series in \( \tau \)**  \[ \rightarrow \text{index } m \in \mathbb{Z} \]

**Chebyshev series in \( \xi \), i.e. 2\pi-Fourier series in arccos} \xi \] \[ \rightarrow \text{index } n \in \mathbb{Z} \]
We work in a space in which the coefficients decay as $O((\kappa_1)^{-|m|}(\kappa_2)^{-|n|})$ in the high frequency limit $|m| + |n| \to \infty$, with $\kappa_1, \kappa_2 > 1$. Such functions are analytic on the open subset of $\mathbb{C} \times \mathbb{C}$ in Figure 5, the infinite strip $|\text{Im}(\tau)| < 2\log\kappa_1$ times the open ellipse with radii $\frac{1}{2}(\kappa_2 \pm 1/\kappa_2)$.

![Figure 5: Domain of analyticity. Here $\pm1$ are not the foci.](image)

We use $\kappa_1 = 65/64$ and $\kappa_2 = 5/4$. Thus, the domain that we obtain is smaller than the one shown in Figure 5. When we restrict to real $\xi$, we get $|\xi| < 41/40$. This explains the earlier inequality $u_- < -u_+/81$.

The obstruction to using ‘big’ $\kappa_1$ and $\kappa_2$ is that one has to avoid singularities (e.g. poles) that the complex analytic extension of the Choptuik spacetime may have. This motivates our use of Chebyshev series instead of power series in $\xi$, because a disk with radius bigger than 1, big enough to contain the interval $[-1, 1]$, may already contain singularities.

We use a low-high frequency decomposition of the identity, $s + (1 - s) = 1$. Here $s$ and $1 - s$ are projection operators to low and high frequencies, respectively. In particular, $s$ has a finite dimensional image. These projections divide the construction into the computer and analytic estimates parts:

- things related to $s$ $\to$ computer
- things related to $1 - s$ $\to$ analytic estimates

The shaded region in Figure 6 indicates the image of $s$. Every $\bullet$ in Figure 6 stands for a finite number of real degrees of freedom. Only non-negative indices $m, n$ are shown, because they determine all, by reality constraints. We actually use a much bigger region: $250 \times 750$.

![Figure 6: Images of $s$ (shaded) and of $1 - s$ (non-shaded).](image)
To work in Fourier-Chebyshev frequency space is very useful, because:

- It reveals the elliptic nature of the problem. In fact, the principal part of the equations is morally multiplication by 
\[ im/2 + \mu(n + 1) \]  
(i is the imaginary unit) 
when \( m, n \geq 0 \), with an inverse that is \( O((m + n)^{-1}) \) as \( m + n \to \infty \). We say morally, because the actual operators in (22), while diagonal in \( m \), are only upper triangular in the index \( n \).

- It disposes of the geometric boundaries (central geodesic and especially the critical light cone) in a seamless way, and one does not specify initial data anywhere. That’s good, because the Choptuik spacetime is supposed to be ‘universal’ after all. By contrast, for alternative approaches not based in frequency space, the geometric boundaries may be unpleasant to deal with.

The common slogan in general relativity that ‘the constraints are satisfied if they are satisfied initially’ does not apply here, because there is no initial data in the first place. Not surprisingly, though, the usual differential identities yield a second elliptic system, this one linear and homogeneous, that is used to show that the constraints are satisfied. All objects related to the constraint equations are marked by ♯.

Our analysis uses \( \ell^1 \) norms. This has several advantages:

- Natural estimate for series convolution.

- Transparent operator norm. For non-weighted \( \ell^1 \), it is the sup of the \( \ell^1 \) norms of the ‘columns’. For example, in finite, say two dimensions,
\[
\left\| \begin{pmatrix} a & b \\ c & d \end{pmatrix} \right\|_{\ell^1} = \sup \left\{ \left\| \begin{pmatrix} a \\ c \end{pmatrix} \right\|_{\ell^1}, \left\| \begin{pmatrix} b \\ d \end{pmatrix} \right\|_{\ell^1} \right\} \quad a, b, c, d \in \mathbb{R}
\]

If the \( \ell^1 \) is weighted, then the sup has to be inversely weighted.

And particularly for coding (think finite dimensions here):

- The \( \ell^1 \) norm can be evaluated over the rationals, for rational components and weights. For this reason, we even use
\[
\| z \|_C = |\text{Re } z| + |\text{Im } z|.
\]

- If an operator is constructed column by column, its \( \ell^1 \) operator norm can be evaluated without ever storing the whole operator at once.
1.2 Overview – basic strategy

From an abstract point of view, we construct a nontrivial solution \( x \) (think metric and scalar field) to a nonlinear system \( C(x) = 0 \), where

\[
C(x) = Ax + B(x, x)
\]

The unknown \( x \) lies in an infinite dimensional real vector space (of Fourier-Chebyshev coefficients), \( A \) is a linear operator, and \( B \) is a symmetric bilinear operator. That the Einstein equations, with or without scalar field, can be written as a system with only quadratic nonlinearities is a basic fact, but often unappreciated.

Even though the vector spaces are infinite dimensional, imagine that there are as many equations as unknowns, i.e. that \( x \) and \( C(x) \) are in vector spaces of ‘equal dimensions’. We thereby ignore the constraint equations in this overview. The computer is used to construct an approximate nontrivial solution \( x_{\text{ref}} \), i.e. one for which \( C(x_{\text{ref}}) \) is ‘small’. With \( x = x_{\text{ref}} + x_{\text{corr}} \), the system \( C(x) = 0 \) becomes the following system for the correction \( x_{\text{corr}} \):

\[
[A + 2B(x_{\text{ref}}, \cdot)]x_{\text{corr}} = -C(x_{\text{ref}}) - B(x_{\text{corr}}, x_{\text{corr}}) \tag{4}
\]

with the notation \( B(a, \cdot)b = B(a, b) \). The term \( -B(x_{\text{corr}}, x_{\text{corr}}) \) can be attenuated arbitrarily, by using a sufficiently good \( x_{\text{ref}} \), because it is the only term that scales quadratically with the distance of \( x_{\text{ref}} \) from the hypothetical solution \( x \). Somewhat more concretely, one will seek \( x_{\text{corr}} \) in a ball with small radius \( R > 0 \), centered at the origin, on which \( -B(x_{\text{corr}}, x_{\text{corr}}) \) will have Lipschitz constant \( \sim R \), and the better \( x_{\text{ref}} \), the smaller one can choose \( R \), the smaller the Lipschitz constant.

Thus, a good \( x_{\text{ref}} \) yields an essentially linear problem for \( x_{\text{corr}} \), and the key task is to show that the linear operator \( A + 2B(x_{\text{ref}}, \cdot) \) has an inverse, and control it. We first reduce the task to that of inverting a certain finite square matrix \( X \), and a robust method to invert a matrix is given by the Neumann series. In fact, if one can find an approximate inverse \( Y \), i.e. such that the operator norm \( \|1 - XY\| < 1 \), then the Neumann series

\[
Y \frac{1}{1-(1-XY)} = Y \sum_{k=0}^{\infty} (1 - XY)^k \tag{5}
\]

is an inverse of \( X \). (It is a right-inverse to begin with, which for finite square matrices is also a left-inverse.) This method gives one a lot of flexibility in the construction of \( Y \). See Section 1.3 for a detailed discussion.

The notation used in this overview is local. To connect this abstract discussion with the actual construction, we note that the role of \( C(x) = 0 \) is played by \( \mathbf{S} \Omega'(\mu, \omega) = 0 \), cf. (24). With tiny modifications, equation (4) becomes the key equation (31). For equation (5), see (58).
1.3 Overview – role of the computer

Computer-assisted analytical proofs have a tradition in dynamical systems, beginning with Lanford’s [L] in 1982. This paper may be the first in general relativity.

We use the computer for the primitive purpose of \textit{number crunching} – neither for symbolic manipulations, nor for proof verification. Our code is portable and yields reproducible results. It \textit{uses integer arithmetic only}. The C source code is in the directory \texttt{sourcecode} (arXiv ancillary files).

The computer is used for the following tasks:

(1a) To \textit{construct} a reference (an approximation to Choptuik’s solution).
(1b) To \textit{estimate} how good the reference is.
(2a) To \textit{construct} an approximate inverse (of a finite square matrix).
(2b) To \textit{estimate} how good the approximate inverse is.
(3) To \textit{estimate} the norm of an operator in Section 4.1.

From a logical point of view, (1a) and (2a) are not strictly required: it would suffice to provide the outputs of (1a) and (2a) in files. For (1a) we do exactly that, see the file \texttt{RefAplusB.dat}. For (2a), such a file would be quite big, and therefore the code is used to construct the approximate inverse \textit{column by column, never all of it at once}.

We have included a tool that can generate better and better references, if used appropriately, and given enough computing resources. See \texttt{ImproveRef} in the file \texttt{choptuik.c}. We have used it to construct \texttt{RefAplusB.dat}. This tool is \textit{not part of the existence proof}.

From a practical point of view, assuming \textasciitilde 2010 equipment:

(1a), (1b) take a few dozen CPU hours, and may be memory intense.
(2a), (2b), (3) take a few thousand CPU hours.

The time consuming tasks (2a), (2b), (3) are \textit{embarrassingly parallel}, they split into many individual and completely independent tasks. Every individual task can also be run on a personal computer.

The bottleneck is the convolution of 2-dim arrays of integers, which we have implemented using integer multiplication from the GMP library, which uses FFT. We use the GCC compiler, and OpenMP. We ran the code on the Brutus HPC cluster at ETH Zurich.

We discuss (2a), (2b) in some detail. Given a real matrix $X$, the task is to construct an approximate inverse $Y$, see Section 1.2. The matrices are $N \times N$, where $N = 654375$ with our choice of parameters. This number
arises roughly as $250 \cdot 750 \cdot 2 \cdot (0.25 + 0.5 + 0.5 + 0.5) = 656250$ with:

- 250 number of Fourier indices, $0 \leq m < 250$, see $s$ in Section 1.1
- 750 number of Chebyshev indices, $0 \leq n < 750$, see $s$ in Section 1.1
- 2 for real and imaginary parts
- 0.25 for every field restricted by a $\mathbb{Z}_2 \times \mathbb{Z}_2$ symmetry
- 0.5 for every field restricted by a $\mathbb{Z}_2$ symmetry

Reality constraints for the zeroth Fourier coefficient yield a value $N$ smaller than 656250. This counting applies to the rows of $X$. For the columns of $X$, one of these degrees of freedom is dropped (a gauge condition that removes translational symmetry in $\tau$), and one is added for $\mu$. See (32). Of course, the role of columns and rows is reversed for $Y$.

Each entry of the matrix $X$ is a dyadic rational, i.e. an integer divided by a power of 2. The matrix $X$ is not stored entry by entry, but arises naturally as a sum of compositions of a small set of operators $O$. Each $O$ is implemented through an efficient algorithm, of which only convolution is non-trivial, and each $O$ is equivalent to a matrix with dyadic rational entries.

There is no useful linear order for the rows and columns of $X$, because there are two frequency indices $m$ and $n$. This makes it hard to visualize $X$. We will simplify our discussion below by pretending, very informally, that there is just one frequency index, and that the rows and columns are arranged in order of ‘increasing frequency’. With this simplification, the matrix $X$ has the structure in Figure 7.

![Figure 7: Matrix $X$, with $N' \approx N/100$.](attachment:image.png)

The square submatrix ➊ is dense and some of its entries are large. The band ➋ is close to the identity, but not very close in the operator norm. The entries in ➌ are extremely small in the operator norm. The entries in ➍ are identically zero. To summarize, $X$ is close to a band matrix in the operator norm. However, the width of the band is in the thousands.
In (2a), the construction of $Y$, only ➊ and ➋ are taken into account. We first apply Gaussian elimination to ➊, with partial pivoting and rounding to dyadic rationals at each step. The output of Gaussian elimination is combined with ➋ to a first naive approximate inverse $Y_{\text{naive}}$. Finally, a truncated Neumann series is used to generate from $Y_{\text{naive}}$ a better approximate inverse $Y$. (For efficiency, our implementation differs slightly from this description.)

This approach to (2a) exploits the approximate sparseness of $X$, and it made the calculation feasible with the resources available to us. In principle, with enough resources, one could apply Gaussian elimination to all of $X$ at once.

In (2b) we calculate the operator norms $\|Y\|$ and $\|1 - XY\|$. This is the only place where ➌ has to be used. Only once we have checked $\|1 - XY\| < 1$ do we know that the construction in (2a) was actually successful. We can then use the Neumann series inequality $\|X^{-1}\| \leq \|Y\|/(1 - \|1 - XY\|)$.

Tasks (2a) and (2b) are embarrassingly parallel, because both the construction of $Y$ and the evaluation of $\|Y\|$ and $\|1 - XY\|$ can be done column by column, see the discussion of the $\ell^1$ operator norm in Section 1.1.

Tasks (2a) and (2b) have to be repeated for the ♯ system, that is used to show that the constraints vanish. Here, $N = 280125 \approx 250 \cdot 750 \cdot 2 \cdot (0.25+0.5)$.

### 1.4 Overview – the invariant $\mu$ and the coordinates $(\tau, \xi)$

The purpose of this section is to motivate the geometric ansatz that we use to construct the Choptuik spacetime. It provides important intuition. However, it is not part of the existence theorem. First, we need three facts.

Let $G$ be the set of germs of $C^\infty$ functions $\mathbb{R} \rightarrow \mathbb{R}$ at the origin $x = 0$, with $f(0) = 0$ and $f'(0) > 0$. Germs are convenient for making local statements about functions, without having to worry about domains; for a definition see Wikipedia. The set $G$ is a group under composition $(\circ)$. Two elements $f, g \in G$ are called conjugate if and only if there is a $\kappa \in G$ such that $\kappa \circ f = g \circ \kappa$. For all $f, g, \kappa \in G$:

**Fact 1.** If $f, g$ are conjugate, then $f'(0) = g'(0)$.

**Fact 2.** If $f'(0) \neq 1$, then $f$ is conjugate to the linear function $x \mapsto f'(0)x$.

**Fact 3.** If $f$ is linear with $f'(0) \neq 1$, and $f \circ \kappa = \kappa \circ f$, then $\kappa$ is linear.

In words: The derivative at the origin is a conjugation invariant (Fact 1), and if it is not equal to one, then it is the only invariant (Fact 2).

The rest of this Section 1.4 is not rigorous. We blur the distinction between a function and its germ, and we use implicitly some very general qualitative properties of the Choptuik spacetime.
The Choptuik spacetime has a conjugation invariant as in Fact 1. To see this, first introduce a set of \textit{incoming null coordinates}. Namely, let \( \text{NullCoord}_- \) be the set of all \( u : \text{(Choptuik spacetime)} \rightarrow \mathbb{R} \) for which:

\[
\begin{cases}
  u \text{ is a spherically symmetric incoming null coordinate, with } du \neq 0 \\
  u = 0 \text{ is the critical light cone of the Choptuik spacetime} \\
  u < 0 \text{ in the interior, } u > 0 \text{ in the exterior}
\end{cases}
\]

The group \( G \) acts on \( \text{NullCoord}_- \), in fact

\[
G \times \text{NullCoord}_- \rightarrow \text{NullCoord}_- \quad (f, u) \mapsto f \circ u
\]

is well defined as a map, and is a group action. This action has an important property: for any two \( u, u' \) in \( \text{NullCoord}_- \), there exists a unique \( f \in G \) with \( f \circ u = u' \). Henceforth, this property is called \textit{regularity}.

Let \( \Theta \) be the self-similarity diffeomorphism (1) of the Choptuik spacetime. If \( u \) is in \( \text{NullCoord}_- \), so is \( u \circ \Theta^{-1} \). By regularity, there is a map

\[
\text{NullCoord}_- \rightarrow G, \ u \mapsto f_u \quad \text{defined by} \quad u \circ \Theta^{-1} = f_u \circ u
\]

We have \( f_{\kappa u} = \kappa \circ f_u \circ \kappa^{-1} \) for all \( \kappa \in G \). By regularity:

**By Fact 1.** \( f'_u(0) \) is an invariant (the same for every \( u \in \text{NullCoord}_- \)).

The constant \( \mu \) used in this paper is defined by \( e^{2\pi \mu} = f'_u(0) \). We anticipate that for the Choptuik spacetime, \( \mu > 0 \) and \( f'_u(0) > 1 \). Therefore:

**By Fact 2.** There exist \( u \in \text{NullCoord}_- \) such that \( f_u \) is linear.

**By Fact 3.** If \( f_u \) and \( f_{u'} \) are linear, then \( f_u = f_{u'} \) and \( u = cu' \) for a \( c > 0 \).

Fix a \( u_- \in \text{NullCoord}_- \) for which \( f_{u_-} \) is linear, \( u_- \circ \Theta^{-1} = e^{2\pi \mu} u_- \). Let \( u_+ \) be the spherically symmetric outgoing null coordinate that satisfies \( u_+ = u_- \) along the central geodesic. Then \( u_+ \circ \Theta^{-1} = e^{2\pi \mu} u_+ \), because it is true on the central geodesic. The 2D coordinate pair \( (u_-, u_+) \) is unique up to joint multiplication by a positive constant.

The 2D coordinate pair \( (\tau, \xi) \) used in this paper can now be defined by

\[
u_\sigma = -(1 + \sigma \xi) \exp(-\mu \tau) \quad \sigma = \pm
\]

By construction, \( \xi = 0 \) is the central geodesic, \( \xi = 1 \) is the critical light cone, and \( (\tau, \xi) \circ \Theta = (\tau + 2\pi, \xi) \). The pair \( (\tau, \xi) \) is unique up to adding a constant to \( \tau \). We compare the two coordinate systems in a table:

| \( (u_-, u_+) \) | \( (u_-, u_+) \circ \Theta = e^{-2\pi \mu} (u_-, u_+) \) | \( \text{ker } du_\sigma \) |
|------------------|--------------------------------|------------------------------|
| \( (\tau, \xi) \) | \( (\tau, \xi) \circ \Theta = (\tau + 2\pi, \xi) \) | \( \text{ker} \{ \sigma d\xi - \mu (1 + \sigma \xi) d\tau \} \) |
In the first case, $\Theta$ depends on $\mu$, but the 2D causal structure doesn’t. In the second case, $\Theta$ doesn’t depend on $\mu$, but the 2D causal structure does.

Either way, the constant $\mu > 0$ appears somewhere. Since it is a geometric invariant of the Choptuik spacetime, $\mu$ cannot be chosen freely before the construction. Rather, it is an unknown and it has to be constructed.

2 Einstein equations coupled to scalar field

The equations for a metric $g$, coupled to a massless scalar field $\phi$, are

$$
\text{Ricci}_g = k \, d\phi \otimes d\phi \quad \text{Einstein field equations}
$$

$$
\Box_g \phi = 0 \quad \text{wave equation}
$$

where $\text{Ricci}_g$ is the Ricci curvature of $g$, the one form $d\phi$ is the differential of $\phi$, and $\Box_g$ is the Laplace-Beltrami operator for $g$. All values for the constant $k > 0$ are equivalent, by rescaling $\phi$. This rescaling is necessary to compare papers that use different values for $k$. This paper uses $k = 2$.

The four-dimensional problem reduces, in the case of spherical symmetry, to a two-dimensional problem:

$$
\text{abstract 4D problem}
\quad \text{Ricci}_g = 2 \, d\phi \otimes d\phi, \quad \Box_g \phi = 0
$$

From a pedagogical perspective, the direction from 4D to 2D (Section 2.1) is easier to understand, because it starts from the basic equations. From a logical perspective, only the direction from 2D to 4D (Section 2.2) is required for the existence theorem that we prove.

We use a frame formalism, because it yields first order, quadratically nonlinear equations. The 2D formulation has more equations than unknowns. The equations are dependent, see the differential identities in Section 2.3.

2.1 From 4D to 2D

Let $(\tau, x^1, x^2, x^3)$ be Cartesian coordinates on $\mathbb{R}^4$. Spherical symmetry means invariance under the standard action of the matrix group $O(3)$ on the coordinates $(x^1, x^2, x^3)$, with $\tau$ fixed. It is convenient to start with Cartesian coordinates, because (as opposed to polar coordinates) they are regular along the line $(x^1, x^2, x^3) = 0$, the set of fixed points of the action. Set

$$
\xi = \sqrt{(x^1)^2 + (x^2)^2 + (x^3)^2}
$$
Let $\mu > 0$ be a constant, and let $Q$ and $\zeta$ be real valued functions that depend only on $\tau$ and $\xi$. Introduce a frame $(e_0, e_1, e_2, e_3)$ and a spherically symmetric metric $g$ with signature $(-, +, +, +)$:

$$e_0 = \frac{\partial}{\partial \tau} + \mu \sum_{k=1}^{3} x^k \frac{\partial}{\partial x^k}$$

$$e_i = \mu \frac{\partial}{\partial x^i} + Q \sum_{k=1}^{3} x^k \left( x^k \frac{\partial}{\partial x^i} - x^i \frac{\partial}{\partial x^k} \right) \quad \text{with } i = 1, 2, 3$$

$$g^{-1} = \exp(2\zeta) \left( -e_0 \otimes e_0 + e_1 \otimes e_1 + e_2 \otimes e_2 + e_3 \otimes e_3 \right)$$

A spherically symmetric spacetime can always be brought into this form, by appropriate choice of the two free functions $Q$ and $\zeta$. We omit a more precise statement or a proof, because it is logically unnecessary for this paper.

We assume $\mu + \xi^2 Q > 0$, which implies that the frame is non-degenerate:

$$e_0 \wedge e_1 \wedge e_2 \wedge e_3 = \mu(\mu + \xi^2 Q)^2 \frac{\partial}{\partial \tau} \wedge \frac{\partial}{\partial x^1} \wedge \frac{\partial}{\partial x^2} \wedge \frac{\partial}{\partial x^3}$$

By construction, the functions $u_\sigma = -(1 + \sigma \xi) \exp(-\mu \tau)$ with $\sigma = \pm$ both solve the Eikonal equation $g^{-1}(du_\sigma, du_\sigma) = 0$. This determines the causal structure of the restriction of the metric to the 2-dimensional plane $(\tau, \xi) \mapsto (\tau, \xi, 0, 0)$. This causal structure depends only on the constant $\mu$, not on $Q$ or $\zeta$. See Figure 8.

![Figure 8: Forward light cones. Exact directions depend on $\mu$. However, $\xi = 1$ is a null hypersurface for all $\mu$, because it is a level set of $u_-$.

Introduce the two radial null vector fields

$$D^\sigma = \sigma e_0 + \sum_{k=1}^{3} \frac{x^k e_k}{\xi}$$
In particular $D^\sigma(\tau) = \sigma$ and $D^\sigma(\xi) = \mu(1 + \sigma \xi)$. Let $\phi$ be another function that depends only on $\tau$ and $\xi$, it plays the role of the scalar field coupled to the Einstein equations. The functions $\zeta, Q, \phi$ are not themselves useful for us. Instead, the basic unknown functions of $\tau$ and $\xi$ that are used throughout the paper (together with the unknown constant $\mu$) are

$$
\begin{align*}
\omega_1 &= 2\xi Q + D^{-}(\zeta + \log(\mu + \xi^2 Q)) + D^{+}(\zeta + \log(\mu + \xi^2 Q)) \\
\omega_2^\sigma &= D^\sigma(\zeta + \log(\mu + \xi^2 Q)) - \sigma \mu \\
\omega_3^\sigma &= D^\sigma(\zeta) - \sigma \mu \\
\omega_4^\sigma &= D^\sigma(\phi)
\end{align*}
$$

with $\sigma = \pm$. A useful property is the invariance of these seven functions under a global conformal transformation of the metric, $\zeta \rightarrow \zeta + \text{const}.$

The equations (8) can be rewritten as

$$
\begin{align*}
Q &= (\omega_1 - \omega_2^- - \omega_2^+)/2\xi) \\
D^\sigma(\log(\mu + Q \xi^2)) &= \omega_2^\sigma - \omega_3^\sigma \\
D^\sigma(\zeta) &= \omega_3^\sigma + \sigma \mu \\
D^\sigma(\phi) &= \omega_4^\sigma
\end{align*}
$$

This can be used to calculate $\text{Ricci}_g(e_m, e_n) - 2e_m(\phi)e_n(\phi)$ with $m, n = 0, 1, 2, 3$ and $\exp(-2\xi)\Box_\phi$ in terms of just $\omega_1, \omega_2^\sigma, \omega_3^\sigma, \omega_4^\sigma$. This lengthy but straightforward calculation is not included. The result is

$$
\begin{align*}
\text{Ricci}_g(e_i, e_j) - 2e_i(\phi)e_j(\phi) &= \frac{\delta_{ij}}{4\xi}(\Omega_1^- + \Omega_1^+ + \Omega_2^- + \Omega_2^+ - \Omega_2^- - \Omega_2^+) \\
&\quad + \frac{x^i x^j}{4\xi^3}(\Omega_1^- + \Omega_1^+ - \Omega_2^- + \Omega_2^+ + \Omega_2^- + \Omega_2^+ + 2\Omega_3^- + 2\Omega_3^+)
\end{align*}
$$

for all $i, j = 1, 2, 3$ and

$$
\begin{align*}
\text{Ricci}_g(e_0, e_0) - 2e_0(\phi)e_0(\phi) &= \frac{1}{2\xi^2}(-\Omega_2^- - \Omega_2^+ + \Omega_2^- + \Omega_2^+ - \Omega_3^- + \Omega_3^+) \\
\text{Ricci}_g(e_0, e_i) - 2e_0(\phi)e_i(\phi) &= \frac{x^i}{2\xi^2}(- \Omega_1^- + \Omega_1^+ - \Omega_3^- + \Omega_3^+)
\end{align*}
$$

exp$(-2\xi)\Box_\phi = \frac{1}{2\xi}(\Omega_4^- + \Omega_4^+)$

Here, by definition:

$$
\begin{align*}
\Omega_1^\sigma(\mu, \omega) &= \xi(D^\sigma + \sigma \mu)(\omega_1) + \mu(2\omega_1) \\
&\quad + \frac{1}{4}(\delta_{12}\omega_1 - 2\omega_2^- \omega_1 - 6\omega_2^+ \omega_1 + 4\omega_2^\sigma \omega_1 + \omega_2^- \omega_2^- - 2\omega_2^- \omega_2^- - 4\omega_2^\sigma \omega_2^- + \omega_2^- \omega_2^\sigma + 4\omega_2^\sigma \omega_2^- - 4\omega_2^\sigma \omega_4^-)
\end{align*}
$$
\[
\begin{align*}
\Omega_\nu^\gamma(\mu, \omega) &= \xi(D^\sigma + \sigma \mu)(\omega_\nu^{-\sigma}) + \mu(\omega_\nu + \omega_\nu^{-\sigma} + \omega_\nu^\sigma) \\
&\quad + \frac{1}{4} \xi(\omega_\nu \omega_1 - 2\omega_\nu \omega_1 - 2\omega_\nu^+ \omega_1 + \omega_\nu^- \omega_1 - 6\omega_\nu^+ \omega_- + \omega_\nu^- \omega_+ )
\end{align*}
\] (11b)

\[
\Omega_\nu^\sigma(\mu, \omega) = \xi(D^\sigma + \sigma \mu)(\omega_\nu^{-\sigma}) + \mu(2\omega_\nu^2 - 2\omega_\nu^\sigma)
\] (11c)

\[
\Omega_\nu^\sigma(\mu, \omega) = \xi(D^\sigma + \sigma \mu)(\omega_\nu^{-\sigma}) + \mu(-\omega_1)
\] (11d)

\[
\Omega_\nu^\sigma(\mu, \omega) = \xi(D^\sigma + \sigma \mu)(\omega_\nu^{-\sigma}) + \mu(\omega_\nu^\sigma + \omega_\nu^-)
\] (11e)

Claim. If Ricci\(_g\) = 2 d\(\phi\) \(\otimes\) d\(\phi\) and \(\Box_g \phi = 0\), then the ten functions \(\Omega_i^\sigma\) with \(i \in \{1, 2, 2^*, 3, 4\}\) and \(\sigma = \pm\) all vanish.

In fact, \([D^-, D^+] = \mu(D^- + D^+)\) and equations (8) imply that \(\Omega_1^\sigma - \Omega_2^\sigma - \Omega_{2^*}^\sigma\) and \(-\Omega_3^+ + \Omega_2^-\) and \(-\Omega_4^+ + \Omega_3^-\) and \(-\Omega_4^+ + \Omega_4^-\) all vanish. By Ricci\(_g\) = 2 d\(\phi\) \(\otimes\) d\(\phi\) and \(\Box_g \phi = 0\), all \(\Omega\)'s vanish.

Remark. The principal parts of the right hand sides of (11) have the directions indicated in Figure 8, and their coefficients vanish at \(\xi = 0\). This degeneration at \(\xi = 0\) is standard for polar coordinates.

2.2 From 2D to 4D

A periodic 2D problem (called 2Dprob) is defined below, every solution of which yields a 4D spacetime as in Section 2.1. The periodicity of 2Dprob corresponds to the fundamental self-similarity diffeomorphism \(\Theta\) of the 4D spacetime. This section is logically independent from Section 2.1.

Prerequisites (2Dpre). Let \(\xi_* > 1\) be constant. Let

\[
(\tau, \xi) \in \mathbb{Z} = (\mathbb{R}/4\pi\mathbb{Z}) \times (-\xi_*, \xi_*)
\] (12)

The set \(\mathbb{Z}\) is a cylinder. The unknowns are a constant \(\mu > 0\) and four real analytic functions \(\omega_1, \omega_2, \omega_3, \omega_4: \mathbb{Z} \to \mathbb{R}\) that satisfy (a) through (d):

(a) Under \((\tau, \xi) \mapsto (\tau + 2\pi, \xi)\), they transform as

\[
(\omega_1, \omega_2, \omega_3, \omega_4) \mapsto (\omega_1, \omega_2, \omega_3, -\omega_4)
\]

That is, three functions are invariant, one changes its sign.

(b) If \(\omega_4\) is invariant under \((\tau, \xi) \mapsto (\tau + T, \xi)\), then \(T \in 4\pi\mathbb{Z}\).
In particular, \(\omega_4\) does not vanish identically.
(c) The function $\omega_1$ satisfies $P \omega_1 = -\omega_1$. See (13).

(d) The inequality $2\mu + \xi(\omega_1 - \omega_2 + P\omega_2) > 0$ holds on $\mathfrak{F}$. See (13).

Here and below, $P$ is defined by

$$ (P f)(\tau, \xi) = f(\tau, -\xi) $$

for every function $f$. Set

$$ D^\sigma = \sigma \frac{\partial}{\partial \tau} + \mu(1 + \sigma \xi) \frac{\partial}{\partial \xi} \quad \sigma = \pm $$

They are well defined as vector fields on $\mathfrak{F}$. Set $\omega_i^- = \omega_i$ and $\omega_i^+ = -P\omega_i$ for $i = 2, 3, 4$. Adopt equations (11) as definitions. The $\Omega$’s are now real valued functions on $\mathfrak{F}$.

**Periodic 2D problem (2Dprob).** Find $\mu$ and $(\omega_1, \omega_2, \omega_3, \omega_4)$ that satisfy 2Dpre and that satisfy $\Omega_1^+ = \Omega_2^+ = \Omega_3^+ = \Omega_4^+ = 0$ identically on $\mathfrak{F}$.

**Claim.** Every solution $\mu$, $(\omega_1, \omega_2, \omega_3, \omega_4)$ to 2Dprob yields a unique real analytic solution $(g, \phi)$ to Ricci $g = 2 d\phi \otimes d\phi$ and $\Box g \phi = 0$, as in Section 2.1, on the open set $\mathbb{R} \times B_{\xi^*}(0) \subset \mathbb{R} \times \mathbb{R}^3$, that satisfies:

- The constants $\mu$ in Sections 2.1 and 2.2 are identified, and $\omega_1, \omega_2^\pm, \omega_3^\pm, \omega_4^\pm$ in Sections 2.1 and 2.2 are identified as functions of $\tau, \xi$ for $\xi \geq 0$.
- $\zeta(0, 0) = 0$ and $\phi(2\pi, 0) = -\phi(0, 0)$.

Furthermore, this unique solution satisfies for all $(\tau, x) \in \mathbb{R} \times B_{\xi^*}(0)$:

$$ Q \circ \Theta = Q $$
$$ \zeta \circ \Theta = \zeta + K \quad \text{with} \quad K = 2\pi \mu - \int_{\tau}^{2\pi} d\tau \omega_3(\tau, 0) $$
$$ \phi \circ \Theta = -\phi $$

where $\Theta : (\tau, x) \mapsto (\tau + 2\pi, x)$ is a global conformal isometry of $g$.

To check this, suppose $\mu$, $(\omega_1, \omega_2, \omega_3, \omega_4)$ solve 2Dprob. Note that $PD^\sigma f = -D^{-\sigma}Pf$ for every function $f$. Recall that $P\omega_1 = -\omega_1$ and $P\omega_i^\sigma = -\omega_i^{-\sigma}$ with $i = 2, 3, 4$, by (c). Therefore, equations (11) imply $P\Omega_i^\sigma = -\Omega_i^{-\sigma}$. It now follows from 2Dprob that $\Omega_1^- = \Omega_2^- = \Omega_2^+ = \Omega_3^- = \Omega_4^- = 0$ on $\mathfrak{F}$. That is, all $\Omega$’s vanish on $\mathfrak{F}$. With this piece of information, we can introduce two real analytic functions $Q, \phi$ on $\mathfrak{F}$, and one real analytic function $\zeta$ on $\mathbb{R} \times (-\xi^*, \xi^*)$, the universal cover of $\mathfrak{F}$, as follows:
Let $Q : \mathbb{R} \to \mathbb{R}$ be given by (9a). It satisfies (15a) and $PQ = Q$.

Let $\zeta : \mathbb{R} \times (-\xi_*, \xi_*) \to \mathbb{R}$ be the unique solution to (9c) and $\zeta(0, 0) = 0$. Such a solution exists, because the one form $\alpha$ on $\mathcal{F}$ given by $\alpha(D^*) = \omega_3^* + \sigma \mu$ is closed:

$$\xi(d\alpha)(D^-, D^+) = \xi D^-(\alpha(D^+)) - \xi D^+(\alpha(D^-)) - \xi \alpha([D^-, D^+])$$

$$= \xi (D^- - \mu)(\omega_3^*) - \xi (D^+ + \mu)(\omega_3^*) = \Omega_3^- - \Omega_4^+ = 0$$

Thus, $d\alpha$ vanishes when $\xi \neq 0$, and by continuity at $\xi = 0$. Then $f = \zeta \circ \Theta - \zeta$ satisfies $df = 0$, and is equal to a constant $K$. The equation $(\frac{\partial}{\partial \tau} \zeta)(\tau, 0) = \mu - \omega_3(\tau, 0)$ implies (15b). The difference $f = P\zeta - \zeta$ satisfies $df = 0$ and $f(\tau, 0) = 0$, and therefore $P\zeta = \zeta$ identically.

Let $\phi : \mathbb{R} \times (-\xi_*, \xi_*) \to \mathbb{R}$ be the unique solution to (9d) and $\phi(2\pi, 0) = -\phi(0, 0)$. Such a solution exists, because the one form $\alpha(D^*) = \omega_4^*$ is closed by $\Omega_1^- - \Omega_4^+ = 0$. The sum $f = \phi \circ \Theta + \phi$ satisfies $df = 0$ and $f(0, 0) = 0$, which implies (15c). It follows that $\phi(\tau + 4\pi, \xi) = \phi(\tau, \xi)$, i.e. $\phi$ is a function on the cylinder, $\phi : \mathcal{F} \to \mathbb{R}$. Finally, $P\phi = \phi$.

Denote by the same symbols $Q, \zeta$ and $\phi$ the corresponding functions on $\mathbb{R} \times B_{\xi*}(0) \subset \mathbb{R} \times \mathbb{R}^3$. Define a frame $(e_0, e_1, e_2, e_3)$ and a metric $g$ by (7). The condition $\mu + \xi^2Q > 0$ follows from (d). The frame, the metric and $\phi$ are real analytic (here $PQ = Q$ and $P\zeta = \zeta$ and $P\phi = \phi$ are used). While (9a), (9c), (9d) hold by definition of $Q, \zeta, \phi$, equation (9b) is now a consequence of equation (9a), of the fact that the definitions of $D^\pm$ in Sections 2.1 and 2.2 are consistent, and of $\Omega_1^+ - \Omega_2^+ - \Omega_2^- = 0$. Therefore, equations (8) hold. The vanishing of all the $\Omega$’s and equations (10) imply that $\text{Ricci}_g - 2 d\phi \otimes d\phi = 0$ and $\Box_g \phi = 0$ when $\xi \neq 0$, and when $\xi = 0$ by continuity of the left hand sides. The uniqueness part of the claim is automatic, because every step of the construction is forced.

2.3 The $\varphi$ system

Suppose $\mu, (\omega_1, \omega_2, \omega_3, \omega_4)$ satisfy 2Dpre, but not necessarily 2Dprob. A straightforward calculation with $[D^-, D^+] = \mu(D^- + D^+)$ and $-D^- = PD^+P$ shows that the $\Omega$’s satisfy a homogeneous differential identity. Namely, with $\Omega_i = \Omega_i^-$ for all $i \in \{1, 2, 2^*, 3, 4\}$ (equation may continue on the next page):

$$0 = \xi \left( \frac{1}{2}(1 - P)(D^+ + \mu)\Omega_1 \right) \left( (D^+ + \mu)\Omega_1 - P(D^+ + \mu)\Omega_2 \right) + \mu \left( \frac{1}{2}(1 + P)\Omega_1 \right) \left( \Omega_1 + \Omega_2 + P\Omega_2 - 2P\Omega_3 \right)$$
Claim. Suppose \( \mu \) and \((\omega_1, \omega_2, \omega_3, \omega_4)\) satisfy \(2D\text{pre}\). If
\[
(1 + P)\Omega_1^+ = \Omega_2^+ = \Omega_3^+ = \Omega_4^+ = 0 \quad \text{on} \quad 3.
\]
then \( P\Omega_1 = -\Omega_1 \) and (this will be referred to as the \( \xi \) system):
\[
0 = \xi \left( \frac{1}{2}(1 - P)(D^+ + \mu)\Omega_1 \right) + \mu \left( \frac{0}{\Omega_1} \right)
+ \frac{\xi}{2} \left\{ \left( \frac{P\omega_2 - P\omega_3 + \omega_2 - \omega_3}{P\omega_2 + \omega_1 - \omega_2} \right) \Omega_1 + \left( \frac{P\omega_3 - \omega_1 - \omega_3}{3P\omega_2 - \omega_1 + \omega_2} \right) \Omega_2 + \frac{P\Omega_2}{2} \right\}.
\]

\[16\]

3 Fourier-Chebyshev series

We reformulate \(2D\text{prob}\) in Section 2.2 as a new problem \(2D\text{probSeries}\) for Fourier-Chebyshev series, see page 27, and introduce handy notation for all the objects in \(2D\text{probSeries}\), to prepare for the analysis in Section 4.

This section is essentially a collection of definitions. Reading through them linearly makes sense from a logical point of view, but is not advisable, because the motivation for each definition lies in the definitions that come after it.
Series. For every \( v = (v_{mn}) \) in the real vector space
\[
\mathcal{V} = \left\{ (v_{mn})_{m,n \in \mathbb{Z}} \in \mathbb{C} \mid v_{mn} = \overline{v_{-m,-n}} \text{ and } v_{mn} = v_{m,-n} \text{ and there are } \alpha, \beta > 0 \text{ with } \sup_{m,n \in \mathbb{Z}} |e^{\alpha|m|+\beta|n|}v_{mn}| < \infty \right\}
\]
we introduce the Fourier in \( \tau \), Chebyshev in \( \xi \) series
\[
\text{ToSeries}(v) = \left( \sum_{m,n \in \mathbb{Z}} v_{mn} \exp\left( \frac{1}{2}im\tau + in\theta \right) \right)_{\theta = \arccos \xi} \tag{17}
\]
It is a function of \((\tau, \xi)\), or a function of \((\tau, \theta)\) that is even in \( \theta \).

Properties of \( (17) \). Let \( v \in \mathcal{V} \).

- There are \( \alpha, \beta > 0 \) as above, depending on \( v \), such that \( (17) \) converges and is analytic jointly in \((\tau, \xi)\) on the open, product subset of \( \mathbb{C} \times \mathbb{C} \):

\[
|\text{Im}(\tau)| < 2\alpha \quad \text{and} \quad \frac{(\text{Re} \xi)^2}{(\cosh \beta)^2} + \frac{(\text{Im} \xi)^2}{(\sinh \beta)^2} < 1
\]
The ellipse contains the real interval \( \xi \in [-1, 1] \). Cf. Figure 5.

- The series \( (17) \) is real when \( \tau \) and \( \xi \) are real.

- In terms of the polynomials Chebyshev \( n(\xi) = \cos(n \arccos \xi) \),
\[
\text{ToSeries}(v) = \sum_{m \in \mathbb{Z}} v_{m0} \exp(\frac{1}{2}im\tau) + 2 \sum_{m \in \mathbb{Z}, n > 0} v_{mn} \exp(\frac{1}{2}im\tau) \text{ Chebyshev}_n(\xi)
\]

Convention: In this section, \( \text{ToSeries} \) is thought of as a map from \( \mathcal{V} \) to maps \((\mathbb{R}/4\pi\mathbb{Z}) \times [-1, 1] \to \mathbb{R} \). Advantage: all functions produced by \( \text{ToSeries} \) have the same domain. By analytic continuation, the identities that we state will automatically hold on appropriate domains in \( \mathbb{C} \times \mathbb{C} \).

Fields and multifields. We refer to elements of \( \mathcal{V} \) as fields, and to tuples of fields as multifields. For fields, we define the real vector spaces:
\[
\begin{align*}
\mathcal{V}_{\text{TwoPiPeriodic}} &= \{ v \in \mathcal{V} \mid v_{mn} = 0 \text{ for all odd } m \} \\
\mathcal{V}_{\text{TwoPiAntiPeriodic}} &= \{ v \in \mathcal{V} \mid v_{mn} = 0 \text{ for all even } m \} \\
\mathcal{V}_{\text{Gauged}} &= \{ v \in \mathcal{V} \mid \text{Re}(v_{10}) = 0 \} \\
\mathcal{V}_{\text{XiOdd}} &= \{ v \in \mathcal{V} \mid v_{mn} = 0 \text{ for all even } n \}
\end{align*}
\]
For multifields:

\[
\mathcal{W} = \mathcal{V}_{\text{TP}} \times \mathcal{V}_{\text{TP}} \times \mathcal{V}_{\text{TP}} \times \mathcal{V}_{\text{TP}} \times \mathcal{V}_{\text{TAP}} \subset \mathcal{V}^5
\]

\[
\mathcal{V} = (\mathcal{V}_{\text{TP}} \cap \mathcal{V}_{\text{XiOdd}}) \times \mathcal{V}_{\text{TP}} \times \mathcal{V}_{\text{TP}} \times \mathcal{V}_{\text{TAP}} \subset \mathcal{V}^4
\]

\[
\mathcal{V}_{\text{Gauged}} = (\mathcal{V}_{\text{TP}} \cap \mathcal{V}_{\text{XiOdd}}) \times \mathcal{V}_{\text{TP}} \times (\mathcal{V}_{\text{TAP}} \cap \mathcal{V}_{\text{Gauged}}) \subset \mathcal{V}^4
\]

\[
\mathcal{V}^2 = (\mathcal{V}_{\text{TP}} \cap \mathcal{V}_{\text{XiOdd}}) \times \mathcal{V}_{\text{TP}} \subset \mathcal{V}^2
\]

with the local notation \( \mathcal{V}_{\text{TP}} = \mathcal{V}_{\text{TauTwoPiPeriodic}} \), \( \mathcal{V}_{\text{TAP}} = \mathcal{V}_{\text{TauTwoPiAntiPeriodic}} \).

Every field \( v \in \mathcal{V} \) is determined by its \( m, n \geq 0 \) elements. Precisely, the map

\[
\mathcal{V} \to \left\{ (v_{mn})_{m,n \geq 0} \subset \mathbb{C} \mid v_{0n} \in \mathbb{R} \text{ and there are } \alpha, \beta > 0 \right. \\
\left. \text{with } \sup_{m,n \geq 0} |e^{\alpha m + \beta n} v_{mn}| < \infty \right\}
\]

\[
v \mapsto v|_{m,n \geq 0}
\]

is bijective, an isomorphism. This useful fact will often be used implicitly.

**Auxiliary linear operator** \( U \). Let \( f = (f_{mn})_{m,n \geq 0} \subset \mathbb{C} \) be a sequence with \( f_{0n} \in \mathbb{R} \), and for which \( |f_{mn}| \) has a polynomial bound in \( m \) and \( n \). For \( k \geq 0 \) define \( U[k,f] : \mathcal{V} \to \mathcal{V} \) by

\[
\forall m, n \geq 0 : \quad (U[k,f]v)_{mn} = f_{mn} v_{m,n+k}
\]

It is a well defined \( \mathcal{V} \to \mathcal{V} \) map. It acts diagonally on the index \( m \), and therefore leaves the subspaces \( \mathcal{V}_{\text{TauTwoPiPeriodic}} \) and \( \mathcal{V}_{\text{TauTwoPiAntiPeriodic}} \) invariant.

As a special case, introduce the operator \( U^\text{sp}_{-1,1} : \mathcal{V} \to \mathcal{V} \) by

\[
\forall m, n \geq 0 : \quad (U^\text{sp}_{-1,1} v)_{mn} = \begin{cases} 0 & \text{if } n = 0 \\ v_{m,n-1} & \text{if } n > 0 \end{cases}
\]

**Auxiliary linear operator** \( V \). Let \( f \) be as above, with \( |f_{mn}| \leq 1 \) for all \( m, n \). For \( k > 0 \), define the linear map \( V[k,f] : \mathcal{V} \to \mathcal{V} \) by

\[
\forall m, n \geq 0 : \quad (V[k,f]v)_{mn} = \sum_{L=0}^{\infty} (-1)^L (U[k,f]^L v)_{mn} = \sum_{L=0}^{\infty} (U[kL,fL]v)_{mn}
\]
with \((f_L)_{mn} = (-1)^L \prod_{\ell=0}^{L-1} f_{m,n+\ell}\). Note that
\[ V[k, f](1 + U[k, f]) = (1 + U[k, f]) V[k, f] = 1 \]
In particular, \(1 + U[k, f]\) is invertible if \(k > 0\) and \(|f_{mn}| \leq 1\) for all \(m, n\).

To see that \(V[k, f] : V \rightarrow V\) is well defined, note that \(|(f_L)_{mn}| \leq 1\) for all \(L, m, n\).

Therefore, if \(\alpha, \beta > 0\) are such that \(\sup_{m,n \geq 0} |e^{\alpha m + \beta n} v_{mn}| < \infty\), then
\[ \sup_{m,n \geq 0} |e^{\alpha m + \beta n} (V[k, f] v_{mn})| \leq (1 - e^{-k\beta})^{-1} \sup_{m,n \geq 0} |e^{\alpha m + \beta n} v_{mn}| < \infty \]
In other words, if \(\alpha, \beta > 0\) work for \(v\), then the same \(\alpha, \beta\) also work for \(V[k, f] v\).

**Notation for** \(U, V\). Three examples illustrate the notation. Here \(i = \sqrt{-1}\).

\[
\begin{align*}
V[2, -1] &= V_{2, -1} = V[2, f] \text{ with } f_{mn} = -1 \\
U[0, \delta_0 n] &= U_{0, \delta_0 n} = U[0, f] \text{ with } f_{mn} = \delta_0 n \text{ (Kronecker delta)} \\
U[1, -im/2 + \mu n] &= U_{1, -im/2 + \mu n} = U[1, f] \text{ with } f_{mn} = -im/2 + \mu n
\end{align*}
\]

**Basic linear operators.** Introduce the \(V \rightarrow V\) linear operators

\[
\begin{align*}
P &= U_{0,(-1)^n} \\
\text{TauDerivative} &= U_{0,im/2} \\
\Xi &= \frac{1}{2}(U_{1,1}^{sp} + U_{1,1} + U_{1,\delta_0 n}) \\
\text{OnePlusXiTimesXiDerivative} &= (2 V_{1, -1} - 1) U_{0, n} \\
\Xi^{-1,\text{reg}} &= 2 U_{1,1} V_{2,1}
\end{align*}
\]
They satisfy (here \(P_{\text{Section 2.2}}\) is \((13)\))

\[
\begin{align*}
\text{ToSeries}(P v) &= P_{\text{Section 2.2}} \text{ToSeries}(v) \quad (18a) \\
\text{ToSeries}(\text{TauDerivative} v) &= \frac{\partial}{\partial \tau} \text{ToSeries}(v) \quad (18b) \\
\text{ToSeries}(\Xi v) &= \xi \text{ToSeries}(v) \quad (18c) \\
\text{ToSeries}(\text{OnePlusXiTimesXiDerivative} v) &= (1 + \xi) \frac{\partial}{\partial \xi} \text{ToSeries}(v) \quad (18d) \\
\text{ToSeries}(\Xi^{-1,\text{reg}} v) &= \xi^{-1} \left( \text{ToSeries}(v) - \text{ToSeries}(v)|_{\xi \rightarrow 0} \right) \quad (18e)
\end{align*}
\]
The operator $\Xi^{-1,\text{reg}}$ is only a left-inverse of $\Xi$:

$$\Xi^{-1,\text{reg}} \Xi = 1 \quad (19a)$$

$$\Xi \Xi^{-1,\text{reg}} = 1 - (U_{0,\delta_0 n} - U_{2,\delta_0 n}) V_{2,1} \quad (19b)$$

The identities (18a), (18b) are checked directly, and for (18c) one only has to use $\xi = \cos \theta = \frac{1}{2}(e^{i\theta} + e^{-i\theta})$. To check (18d) and (18e), observe that

$$\mathrm{ToSeries}(v) = \mathrm{ToSeries}(\frac{1}{2}(U^p_{1,1} - U_{1,1} - U_{0,\delta_0 n}) U_{0,n} v) \quad (20a)$$

$$\mathrm{ToSeries}(v)|_{\xi \to 0} = \mathrm{ToSeries}((U_{0,\delta_0 n} - U_{2,\delta_0 n}) V_{2,1} v) \quad (20b)$$

with $\xi = \cos \theta$ in (20a). Here $\sin \theta \frac{\partial}{\partial \theta}$ has to be moved inside $\mathrm{ToSeries}$ as a whole, because the definition of $\mathcal{V}$ only allows even functions of $\theta$. Multiply (18d) by $(1 - \xi)$ and use $(1 - \xi^2) \frac{\partial}{\partial \xi} = -\sin \theta \frac{\partial}{\partial \theta}$ and (20a) and (18c). Multiply (18e) by $\xi$ and use (18c) and (20b). This reduces (18d) and (18e) to the operator identities

$$(U^p_{1,1} + U_{1,1} + U_{1,\delta_0 n} - 2) (2 V_{1,-1} - 1) U_{0,n} = (U^p_{1,1} - U_{1,1} - U_{1,\delta_0 n}) U_{0,n}$$

$$(U^p_{1,1} + U_{1,1} + U_{1,\delta_0 n}) U_{1,1} V_{2,1} = 1 - (U_{0,\delta_0 n} - U_{2,\delta_0 n}) V_{2,1}$$

The next step is to remove all $V$'s. In the second line, just multiply from the right by the invertible $1 + U_{1,1}$ to remove $V_{2,1}$. The first line requires an extra step: add the vanishing term $2 U_{0,\delta_0 n} U_{0,n}$ to the left hand side, obtain a sufficient identity by removing the three occurrences of $U_{0,n}$, only then multiply from the right by the invertible $1 + U_{1,1} = 1 - U_{1,1}$ to remove $V_{1,-1}$. Check the resulting quadratic $U$ identities using $U^p_{1,1} U_{1,1} = 1 - U_{0,\delta_0 n}$ and $U_{k,f} U_{\ell,h} = U_{k+\ell,0}$ with $h_{mn} = f_{mn} g_{m,n+k}$.

**Convolution.** Define the $\mathbb{R}$-bilinear convolution $*: \mathcal{V} \times \mathcal{V} \to \mathcal{V}$ by

$$\forall m, n \in \mathbb{Z} : \quad (v * w)_{mn} = \sum_{m_1, n_1, m_2, n_2 \in \mathbb{Z}} v_{m_1, n_1} w_{m_2, n_2}$$

It satisfies $\mathrm{ToSeries}(v * w) = \mathrm{ToSeries}(v) \mathrm{ToSeries}(w)$.

**The J and K operators.** Let $\mu > 0$. Introduce the $\mathcal{V} \to \mathcal{V}$ linear operators

$$J = \text{OnePlusXiTimesXiDerivative} + 1$$

$$J\mu = \text{TauDerivative} + \mu J$$

$$K = \frac{1}{2}(J + P J P)$$

$$K\mu = \text{TauDerivative} + \mu K = \frac{1}{2}(J\mu + P J\mu P)$$

23
with \( \text{ToSeries}(J, \nu) = (D^\dagger_{\text{Section 2.2}} + \mu) \text{ToSeries}(\nu) \). Note that

\[
\frac{1}{2}(1 + \sigma P) J, \mu \frac{1}{2}(1 + \sigma P) = K, \mu \frac{1}{2}(1 + \sigma P) \quad \sigma = \pm
\] (21)

Equivalent definitions of the above operators, and expressions for the inverses of \( J \) and \( K \), with \( L, \mu = U, 0, \text{im}/2 + \mu(n+1) \) and \( L,\mu^{-1} = U[0, \frac{1}{\text{im}/2 + \mu(n+1)}] \), are:

\[
\begin{align*}
J &= V_{1, -1} \left( U_{0, n+1} + U_{1, n} \right) \\
J, \mu &= V_{1, -1} \left( U_{0, \text{im}/2 + \mu(n+1)} + U_{1, -\text{im}/2 + \mu(n+1)} \right) \\
&= V_{1, -1} L, \mu \left( 1 + U[1, \frac{-\text{im}/2 + \mu(n+1)}{\text{im}/2 + \mu(n+1)}] \right) \\
J,\mu^{-1} &= V[1, \frac{-\text{im}/2 + \mu(n+1)}{\text{im}/2 + \mu(n+1)}] L,\mu^{-1} \left( 1 + U_{1, -1} \right)
\end{align*}
\] (22a)

and

\[
\begin{align*}
K &= V_{2, -1} \left( U_{0, n+1} + U_{2, n+1} \right) \\
K, \mu &= V_{2, -1} \left( U_{0, +\text{im}/2 + \mu(n+1)} + U_{2, -\text{im}/2 + \mu(n+1)} \right) \\
&= V_{2, -1} L, \mu \left( 1 + U[2, \frac{-\text{im}/2 + \mu(n+1)}{\text{im}/2 + \mu(n+1)}] \right) \\
K,\mu^{-1} &= V[2, \frac{-\text{im}/2 + \mu(n+1)}{\text{im}/2 + \mu(n+1)}] L,\mu^{-1} \left( 1 + U_{2, -1} \right)
\end{align*}
\] (22b)

To check \( K \) in (22b), note that \( P V_{k, f} P = V_{k, (-1)^f f} \) and \( P V_{k, f} P = V_{k, (-1)^f f} \), and

\[
2K \equiv P J, \mu P = V_{1, -1}(U_{0, n+1} + U_{1, n}) + (P V_{1, -1} P)(P(U_{0, n+1} + U_{1, n})P) \\
= V_{1, -1}(U_{0, n+1} + U_{1, n}) + V_{1, 1}(U_{0, n+1} - U_{1, n}) \\
= V_{2, -1}(1 + U_{1, 1})(U_{0, n+1} + U_{1, n}) + V_{2, -1}(1 + U_{1, -1})(U_{0, n+1} - U_{1, n})
\]

Last step: \( V_{2, -1} = V_{1, \sigma} V_{1, -\sigma} \) for \( \sigma = \pm \), because \( 1 + U_{2, -1} = (1 + U_{1, -\sigma})(1 + U_{1, \sigma}) \).

---

**Linear operators for multifields.** Set

\[
S = \Xi^{-1, \text{reg}} \circ \begin{pmatrix}
\frac{1}{2}(1 + P) & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 1
\end{pmatrix}
= \begin{pmatrix}
\frac{1}{2}(1 - P) & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 1
\end{pmatrix} \circ \Xi^{-1, \text{reg}} : \mathcal{W} \to \mathcal{V}
\]

\[
S^\sharp = \begin{pmatrix}
\frac{1}{2}(1 - P) & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & P \\
0 & 0 & 0 & 0 & 0
\end{pmatrix} \circ \Xi^{-1, \text{reg}} : \mathcal{W} \to \mathcal{V}^\sharp
\]

24
The operators $S$ and $S^\#$ will be used to split the equations into two parts. The part selected by $S$ has ‘as many equations as unknowns’, the part selected by $S^\#$ are the constraint equations. For $\mu > 0$ introduce

$$H_\mu = \begin{pmatrix} J_\mu & 0 & 0 & 0 \\ 0 & J_\mu & 0 & 0 \\ 0 & -J_\mu P & 0 & 0 \\ 0 & 0 & J_\mu & 0 \end{pmatrix} : \mathcal{V} \to \mathcal{W}$$

$$\mathcal{J} = \text{diag}(K, J, J, J) : \mathcal{V} \to \mathcal{V}$$

$$J_\mu = \text{diag}(K_\mu, J_\mu, J_\mu, J_\mu) = \text{TauDerivative} + \mu \mathcal{J} : \mathcal{V} \to \mathcal{V}$$

and note that $J_\mu^{-1} = \text{diag}(K_\mu^{-1}, J_\mu^{-1}, J_\mu^{-1}, J_\mu^{-1})$. Note that $\mathcal{J}, J_\mu$ map $\mathcal{V} \to \mathcal{V}$ by $[P, K] = [P, K_\mu] = 0$. The definition of $\mathcal{V}$ and (19a), (21) imply $J_\mu = S \Xi H_\mu$.

---

**The operators $\Gamma_1$ and $\Gamma_2$.** Define the linear operator $\Gamma_1 : \mathcal{V} \to \mathcal{W}$ by

$$\Gamma_1 v = \begin{pmatrix} 2v_1 \\ v_1 + v_2 - Pv_2 \\ 2Pv_3 - 2Pv_2 \\ -v_1 \\ v_4 - Pv_4 \end{pmatrix}$$

with $v = (v_1, \ldots, v_4)$. As required, $\Gamma_1 v \in \mathcal{W}$. Define the symmetric, bilinear operator $\Gamma_2 : \mathcal{V} \times \mathcal{V} \to \mathcal{W}$ by (equation may continue on the next page)

$$\Gamma_2(v, w) =$$

$$\frac{1}{4} \begin{pmatrix} 3Pv_2 - 2Pv_3 + v_1 - v_2 \\ Pv_2 + v_1 - v_2 \\ 0 \\ -Pv_2 - v_1 + v_2 \\ 0 \end{pmatrix} * w_1 + \frac{1}{2} \begin{pmatrix} Pv_2 + 2Pv_3 + v_1 + v_2 \\ 2Pv_2 + 2v_2 \\ -2Pv_2 + 2Pv_3 \\ -Pv_2 - v_2 \\ Pv_4 + v_4 \end{pmatrix} * \begin{pmatrix} w_2 + Pw_2 \\ 2v_1 \\ 2Pv_2 - 2Pv_3 \\ v_1 \\ Pv_4 - v_4 \end{pmatrix}$$
where \( * \) is convolution. As required, \( \Gamma_2(v, w) = \Gamma_2(w, v) \) and \( \Gamma_2(v, w) \in \mathcal{W} \).

For later reference (equation may continue on the next page):

\[
S \Xi \Gamma_2(v, w) = \frac{1}{4} \begin{pmatrix}
    P v_2 + v_2 - P v_3 - v_3 \\
    v_1 - v_2 + P v_2 \\
    -v_1 + v_2 - P v_2 \\
    0
\end{pmatrix} * w_1 + \\
\frac{1}{2} \begin{pmatrix}
    v_1 + P v_3 - v_3 \\
    2v_2 + 2P v_2 \\
    v_4 + v_4 \\
    P v_2 + v_2
\end{pmatrix} * w_2 + \\
\frac{1}{2} \begin{pmatrix}
    0 \\
    v_1 \\
    P v_1 - v_4 \\
    v_4 - P v_4
\end{pmatrix} * w_3 + \\
\frac{1}{2} \begin{pmatrix}
    0 \\
    0 \\
    0 \\
    0
\end{pmatrix} * w_4
\]

The nonlinear operator \( \Omega^+ : (0, \infty) \times \mathcal{V}_{\text{Gauged}} \rightarrow \mathcal{W} \). Define

\[
\Omega^+ (\lambda, v) = \Xi H_\lambda v + \lambda \Gamma_1 v + \Xi \Gamma_2(v, v)
\]

with components denoted \( \Omega^+ = (\Omega_1^+, \Omega_2^+, \Omega_3^+, \Omega_4^+) \). By construction,

\[
\text{ToSeries}(\Omega^+ (\lambda, v)) = \Omega^+_{\text{Section 2.2}} (\lambda, \text{ToSeries}(v))
\]

where \( \text{ToSeries} \) is applied component by component. Note that \( \Omega^+_{\text{Section 2.2}} \) redirects to (11), but that (11) must be interpreted as in Section 2.2.
Periodic 2D problem for Fourier-Chebyshev series (2DprobSeries).

Find a solution \((\mu, \omega) \in (0, \infty) \times \mathcal{V}_{\text{Gauged}}\) to \(\Omega^+ (\mu, \omega) = 0\).

By construction, in particular (25):

**Claim.** If \((\mu, \omega)\) solves 2DprobSeries, then the pair \((\mu, \text{ToSeries}(\omega))\), as a map on \(\mathcal{V}_{\text{Section 2.2}}\) for some \(\xi_* > 1\), solves 2Dpre and 2Dprob in Section 2.2, except for (b) and (d), which must be checked separately.

**Remark.** It is convenient to split \(\Omega^+ = 0\) into two parts. We have:

\[ S\Omega^+ = 0 \text{ and } S^\# \Omega^+ = 0 \quad \iff \quad \Omega^+ = 0 \]

The direction \(\implies\) would be immediate from the definitions of \(S\) and \(S^\#\), if \(\Xi^{-1}\text{-reg} \text{ had a left inverse}\). Nevertheless, the following observations yield \(\implies\):

- The first and third terms on the right hand side of (24) are in the image of \(\Xi\), and \(\Xi \Xi^{-1}\text{-reg} \Xi = \Xi\).

- The components 1, 2, 4, 5 of \(\Gamma_1 \mathbf{v}\) are all in the image of \(1 - P\), and \(\Xi \Xi^{-1}\text{-reg}(1 - P) = (1 - P)\). Component 3 of \(\Gamma_1 \mathbf{v}\) is annihilated by \(S\).

**The \(\sharp\) system.** Introduce the \(\mathcal{V}^\# \to \mathcal{V}^\#\) linear operators

\[
\mathcal{J}^\# = \text{diag}(K, \beta) \\
\mathcal{J}^\#_\mu = \text{diag}(K_\mu, J_\mu) = \text{TauDerivative} + \mu \mathcal{J}^\#
\]

\[
\Gamma^\#_1 \mathbf{w} = \begin{pmatrix} 0 \\ w_1 \end{pmatrix}
\]

and the \(\Gamma^\#_2 : \mathcal{V} \times \mathcal{V}^\# \to \mathcal{V}^\#\) bilinear operator

\[
\Gamma^\#_2 (\mathbf{v}, \mathbf{w}) = \frac{1}{2} \left( \begin{array}{c} v_2 + P v_2 - P v_3 - v_3 \\ v_1 - v_2 + P v_2 \end{array} \right) * w_1 \\
+ \frac{1}{2} \left( \begin{array}{c} -v_1 + P v_3 - v_3 \\ -v_1 + v_2 + 3P v_2 \end{array} \right) * \frac{w_{2\sharp} + P w_{2\sharp}}{2} \\
+ \frac{1}{2} \left( \begin{array}{c} v_2 + P v_2 + P v_3 + v_3 \\ -v_1 + v_2 + 3P v_2 \end{array} \right) * \frac{w_{2\sharp} - P w_{2\sharp}}{2}
\]

27
where, $v = (v_1, v_2, v_3, v_4)$ and $w = (w_1, w_2)$.

**Claim.** If $(\mu, \omega) \in (0, \infty) \times V_{\text{Gauged}}$ is a solution to $S\Omega^+(\mu, \omega) = 0$, then $\omega^\sharp = S\Omega^+(\mu, \omega)$ satisfies the linear homogeneous identity

$$J^\sharp_\mu \omega^\sharp + \mu \Xi^{-1, \text{reg}} \Gamma^1_\mu \omega^\sharp + \Gamma^2_2(\omega, \omega^\sharp) = 0$$

(26)

See (16). Note that $\text{ToSeries}(\omega^\sharp) = (\Omega_1, \Omega_2)$ Section 2.3 by (25) and $S\Omega^+ = 0$.

## 4 Approximate solution yields true solution

This section contains the analysis. We rearrange $S\Omega^+ = 0$, solve it with the contraction mapping principle, and then use the $\sharp$ system to show that $\Omega^+ = 0$. **In other words, we solve 2DprobSeries.** The calculations are modulo definitions (e.g. choice of explicit parameter values) and assumptions (e.g. computer assisted results) that we postpone to Section 5. For convenience, things that we postpone to Section 5 are tagged by ♣.

### Cutoff operator.

Fix integers $m(s) \geq 2$ and $n(s) \geq 1$. Define $s : V \to V$ and $\mathbf{s} : V \to V$ by $s = \text{diag}(s, s, s, s)$ and

$$(sv)_{mn} = \begin{cases} v_{mn} & \text{if } |m| < m(s) \text{ and } |n| < n(s) \\ 0 & \text{otherwise} \end{cases}$$

### Reference.

Fix a reference $(\mu_{\text{ref}}, \omega_{\text{ref}}) \in (0, \infty) \times V_{\text{Gauged}}$. Set

$$(\mu, \omega) = (\mu_{\text{ref}}, \omega_{\text{ref}}) + (\mu_{\text{corr}}, \omega_{\text{corr}})$$

(27a)

This is a change of variables between the unknown $(\mu, \omega)$ and the new unknown $(\mu_{\text{corr}}, \omega_{\text{corr}}) \in (-\mu_{\text{ref}}, \infty) \times V_{\text{Gauged}}$. Both will be used simultaneously, as convenient, with the understanding that they are always given in terms of one another by (27a). The condition $\mu_{\text{corr}} > -\mu_{\text{ref}}$ must be kept in mind. It is convenient to split the reference field itself into two parts, i.e. to fix $(\mu_{\text{refA}}, \omega_{\text{refA}}) \in (0, \infty) \times V_{\text{Gauged}}$ and to fix $(\mu_{\text{refB}}, \omega_{\text{refB}}) \in (-\mu_{\text{refA}}, \infty) \times V_{\text{Gauged}}$, and to set

$$(\mu_{\text{ref}}, \omega_{\text{ref}}) = (\mu_{\text{refA}}, \omega_{\text{refA}}) + (\mu_{\text{refB}}, \omega_{\text{refB}})$$

(27b)

Informally, refA is the main part, refB is for fine tuning. The calculations are organized in such a way that the most time consuming computer calculations
only involve refA. If the reader wanted to rigorously construct more accurate approximations to the Choptuik solution than those stated in this paper, he or she could use the same refA, but a better refB. The assumption \( \mu_{\text{refA}} > 0 \) implies that \( {\bf J}_{\mu_{\text{refA}}} \) and \( {\bf J}_{\mu_{\text{refA}}}^{-1} \) are defined. For convenience, suppose

\[
(1 - s)\omega_{\text{refA}} = 0 \quad \bullet 5
\]

(28)

In particular, \( \omega_{\text{refA}} \) has only finitely many nonzero components.

---

**Rearranging \( S\Omega^+(\mu, \omega) = 0 \): informal version.** Set \( C = S\Omega^+(\mu, \omega) - S\Omega^+(\mu_{\text{ref}}, \omega_{\text{ref}}) \), and use the replacements (27a) and (27b) to exhaustion. Use the distributive law to multiply everything out. Clearly, \( C \) is quadratic in \((\mu_{\text{corr}}, \omega_{\text{corr}})\) without constant term. Split \( C = C_1 + C_2 \) where \( C_1 \) are all those terms in \( C \) that satisfy both of:

- They are homogeneous of degree 1 in \((\mu_{\text{corr}}, \omega_{\text{corr}})\).
- They do not involve \((\mu_{\text{refB}}, \omega_{\text{refB}})\).

All the remaining terms go into \( C_2 \). At this point, write

\[ C_1 = S\Omega^+(\mu, \omega) - S\Omega^+(\mu_{\text{ref}}, \omega_{\text{ref}}) - C_2 \]

By construction, \( C_1 \) can be decomposed as \( C_1 = {\bf J}_{\mu_{\text{refA}}} \omega_{\text{corr}} + \mu_{\text{corr}}a + A\omega_{\text{corr}} \), where \( a \) is a multifield, and \( A \) is a linear operator. For high frequencies the term \( {\bf J}_{\mu_{\text{refA}}} \) dominates. Therefore split \( A \) into the low-to-low frequency part \( sAs \), and the rest \( A - sAs \), and move the latter to the right:

\[
{\bf J}_{\mu_{\text{refA}}} \omega_{\text{corr}} + \mu_{\text{corr}}a + sAs\omega_{\text{corr}} =
S\Omega^+(\mu, \omega) - S\Omega^+(\mu_{\text{ref}}, \omega_{\text{ref}}) - C_2 - (A - sAs)\omega_{\text{corr}}
\]

We obtain a rearrangement of \( S\Omega^+ = 0 \) that will be useful to apply the contraction mapping principle, namely:

\[
S\Omega^+(\mu, \omega) = 0 \iff \begin{cases}
\omega_{\text{corr}} + {\bf J}_{\mu_{\text{refA}}}^{-1} (\mu_{\text{corr}}a + sAs\omega_{\text{corr}}) \\
= {\bf J}_{\mu_{\text{refA}}}^{-1} ( - S\Omega^+(\mu_{\text{ref}}, \omega_{\text{ref}}) - C_2 - (A - sAs)\omega_{\text{corr}})
\end{cases}
\]
Rearranging $S\Omega^+(\mu, \omega) = 0$: rigorous version. Let $C, C_1, C_2, a \in \mathcal{V}$ and the linear operator $A : \mathcal{V} \to \mathcal{V}$ be given by:

$$
C = J_{\mu_{ref}}\omega_{\text{corr}} + \mu_{\text{corr}}(J + S\Gamma_1)\omega_{\text{ref}} + \mu_{\text{ref}}S\Gamma_1\omega_{\text{corr}} + 2S\Xi\Gamma_2(\omega_{\text{ref}}, \omega_{\text{corr}}) + \mu_{\text{corr}}(J + S\Gamma_1)\omega_{\text{corr}} + S\Xi\Gamma_2(\omega_{\text{corr}}, \omega_{\text{corr}})
$$

$$
C_1 = J_{\mu_{\text{refA}}}\omega_{\text{corr}} + \mu_{\text{corr}}(J + S\Gamma_1)\omega_{\text{refA}} + \mu_{\text{refA}}S\Gamma_1\omega_{\text{corr}} + 2S\Xi\Gamma_2(\omega_{\text{refA}}, \omega_{\text{corr}})
$$

$$
C_2 = \mu_{\text{refB}}J\omega_{\text{corr}} + \mu_{\text{corr}}(J + S\Gamma_1)\omega_{\text{refB}} + \mu_{\text{refB}}S\Gamma_1\omega_{\text{corr}} + 2S\Xi\Gamma_2(\omega_{\text{refB}}, \omega_{\text{corr}}) + \mu_{\text{corr}}(J + S\Gamma_1)\omega_{\text{corr}} + S\Xi\Gamma_2(\omega_{\text{corr}}, \omega_{\text{corr}})
$$

$$
a = (J + S\Gamma_1)\omega_{\text{ref}}
$$

$$
A = \mu_{\text{refA}}S\Gamma_1 + 2S\Xi\Gamma_2(\omega_{\text{refA}}, \cdot)
$$

(29)

It is now convenient to introduce the linear map (there are several equivalent ways to write this definition, because $a = s\cdot a$ and $J^{-1}_{\mu_{\text{refA}}}s = sJ^{-1}_{\mu_{\text{refA}}}(a)$):

$$
\mathbb{U} : \mathbb{R} \oplus \mathcal{V}_{\text{Gauged}} \to \mathcal{V}
$$

$$
\lambda \oplus v \mapsto v + J^{-1}_{\mu_{\text{refA}}}(\lambda a + sAsv)
$$

and the nonlinear map $\star : \mathbb{R} \oplus \mathcal{V}_{\text{Gauged}} \to \mathcal{V}$ by

$$
\star(\lambda, v) = -J^{-1}_{\mu_{\text{refA}}}S\Omega^+(\mu, \omega_{\text{ref}})
$$

$$
- J^{-1}_{\mu_{\text{refA}}} \left\{ \mu_{\text{refB}}Jv + \lambda(J + S\Gamma_1)\omega_{\text{refB}} + \mu_{\text{refB}}S\Gamma_1v + 2S\Xi\Gamma_2(\omega_{\text{refB}}, v) \right\}
$$

$$
- J^{-1}_{\mu_{\text{refA}}} \left\{ \lambda(J + S\Gamma_1)v + S\Xi\Gamma_2(v, v) \right\}
$$

$$
- J^{-1}_{\mu_{\text{refA}}} (A - sAs)v
$$

(30)

By construction,

$$
S\Omega^+(\mu, \omega) = 0 \iff \mathbb{U}(\mu_{\text{corr}} \oplus \omega_{\text{corr}}) = \star(\mu_{\text{corr}}, \omega_{\text{corr}})
$$

(31)

Remark. Domain and range of $\mathbb{U}$ decompose as

$$
(\mathbb{R} \oplus (\mathcal{V}_{\text{Gauged}} \cap \text{image } s)) \oplus \text{image}(1 - s) \to (\text{image } s) \oplus (\text{image } (1 - s))
$$

(32)

Note that $\text{image}(1 - s) \subset \mathcal{V}_{\text{Gauged}}$ by $m(s) \geq 2$ and $n(s) \geq 1$. By construction, $\mathbb{U}$ is block diagonal with respect to this decomposition. Since the high-to-high frequency block $\text{image}(1 - s) \to \text{image}(1 - s)$ is the identity, the operator $\mathbb{U}$ is invertible if and only if its low-to-low frequency block $\mathbb{R} \oplus (\mathcal{V}_{\text{Gauged}} \cap \text{image } s) \to \text{image } s$ is invertible, a finite square matrix.
We do not introduce a special name for this subspace.

This convolution estimate is sharp, in the sense that
\[ \|v * w\|_\mathcal{V} \leq \|v\|_\mathcal{V} \|w\|_\mathcal{V} \]

Note that \( \| \cdot \|_\mathcal{C} \) is a norm on \( \mathcal{C} \), viewed as a real vector space, and \( |z| \leq \|z\|_\mathcal{C} \leq \sqrt{2} |z| \) and \( \|z_1 z_2\|_\mathcal{C} \leq \|z_1\|_\mathcal{C} \|z_2\|_\mathcal{C} \).

Note that \( \| \cdot \|_\mathcal{V} \) is not a norm on \( \mathcal{V} \), but only on \( \{ v \in \mathcal{V} \mid \|v\|_\mathcal{V} < \infty \} \subset \mathcal{V} \).

We do not introduce a special name for this subspace.

---

**Weighted \( \ell^1 \) norms.** Fix constants \( \kappa_1, \kappa_2 > 1 \) and \( \kappa_* > 0 \). Set

\[
\|z\|_\mathcal{C} = |\text{Re } z| + |\text{Im } z| \\
\|v\|_\mathcal{V} = \sum_{m,n \in \mathbb{Z}} (\kappa_1)^{|m|}(\kappa_2)^{|n|}\|v_{mn}\|_\mathcal{C} \\
= \sum_{m,n \geq 0}(2 - \delta_{m0})(2 - \delta_{n0})(\kappa_1)^{m}(\kappa_2)^{n}\|v_{mn}\|_\mathcal{C} \\
\|v\|_\mathcal{V} = \|v_1\|_\mathcal{V} + \|v_2\|_\mathcal{V} + \|v_3\|_\mathcal{V} + \|v_4\|_\mathcal{V} \\
\|\lambda \oplus v\|_{\mathcal{R}\oplus \mathcal{V}} = \kappa_*|\lambda| + \|v\|_\mathcal{V}
\]

with \( v = (v_1, v_2, v_3, v_4) \in \mathcal{V} \). Set

\[
\|O\|_{Y \leftarrow X} = \sup \{ \|Ox\|_\mathcal{Y} \mid x \in X \text{ with } \|x\|_X = 1 \}
\]

Then \( \|O'O\|_{Z \leftarrow X} \leq \|O'\|_{Z \leftarrow Y} \|O\|_{Y \leftarrow X} \).

---

**Convolution estimate.** The estimate \( \|v * w\|_\mathcal{V} \leq \|v\|_\mathcal{V} \|w\|_\mathcal{V} \) follows from

\[
\|v * w\|_\mathcal{V} = \sum_{m,n \in \mathbb{Z}} (\kappa_1)^{|m|}(\kappa_2)^{|n|}\|v_{m,n}w_{m,n}\|_\mathcal{C} \\
\leq \sum_{m,n \in \mathbb{Z}} (\kappa_1)^{|m|}(\kappa_2)^{|n|}\|v_{m,n}\|_\mathcal{C} \|w_{m,n}\|_\mathcal{C} \\
\leq \sum_{m_1,n_1,m_2,n_2 \in \mathbb{Z}} (\kappa_1)^{|m_1|+|m_2|}(\kappa_2)^{|n_1|+|n_2|}\|v_{m_1,n_1}\|_\mathcal{C} \|w_{m_2,n_2}\|_\mathcal{C} \\
\leq \sum_{m_1,n_1,m_2,n_2 \in \mathbb{Z}} (\kappa_1)^{|m_1|+|m_2|}(\kappa_2)^{|n_1|+|n_2|}\|v_{m_1,n_1}\|_\mathcal{C} \|w_{m_2,n_2}\|_\mathcal{C}
\]

Here, \( \|z_1 z_2\|_\mathcal{C} \leq \|z_1\|_\mathcal{C} \|z_2\|_\mathcal{C} \) and the assumption \( \kappa_1, \kappa_2 > 1 \) are used. This convolution estimate is sharp, in the sense that \( \|(v*)\|_{\mathcal{V} \leftarrow Y} = \|v\|_\mathcal{V} \).
Estimate for $\Gamma_2$.

\[
\|S \Xi \Gamma_2(v, \cdot)\|_{v \to v} \leq \max \left\{ \left\| \begin{pmatrix}
\frac{1}{4} & 0 & -\frac{1}{2} \\
0 & -\frac{1}{2} & 0 \\
-\frac{1}{2} & 0 & 0
\end{pmatrix} 
\right\|_{v}, \left\| \begin{pmatrix}
\frac{1}{4} & 0 & -\frac{1}{2} \\
0 & -\frac{1}{2} & 0 \\
-\frac{1}{2} & 0 & 0
\end{pmatrix}
\right\|_{v}
\right\}
\]

To prove this estimate, use (23) and

\[
\|v\|_v = \|v_1\|_v + \frac{1}{2}\|v_2 + P v_2\|_v + \frac{1}{2}\|v_2 - P v_2\|_v
+ \frac{1}{2}\|v_3\|_v + \frac{1}{2}\|v_3 - P v_3\|_v + \frac{1}{2}\|v_4 + P v_4\|_v + \frac{1}{2}\|v_4 - P v_4\|_v
\]

As a corollary,

\[
\|S \Xi \Gamma_2(v, w)\|_v \leq 3\|v\|_v\|w\|_v \tag{34}
\]

Estimates for the auxiliary operators $U$ and $V$.

\[
\begin{align*}
\|U[k, f]\|_{v \to v} & \leq (\kappa_2)^{-k} \sup_{m,n \geq 0} |f_{mn}| \leq C_f (\kappa_2)^{-k} \sup_{m,n \geq 0} |f_{mn}| \tag{35a}
\|V[k, f]\|_{v \to v} & \leq C_f (1 - (\kappa_2)^{-k})^{-1} \tag{35b}
\end{align*}
\]

with $C_f = 1$ if $f_{mn} \in \mathbb{R}$ for all $m, n$, otherwise $C_f = \sqrt{2}$.

For $V$ we assume, as always, that $k > 0$ and $|f_{mn}| \leq 1$ for all $m, n$.

Proof: Let $c_{mn} = (2 - \delta_{m0})(2 - \delta_{n0})$ for all $m, n \geq 0$. Then

\[
\|U[k, f]\|_v = \sum_{m, n \geq 0} c_{mn}(\kappa_1)^m(\kappa_2)^n |f_{mn}|v_{m,n+k} \|_v \\
\leq (\kappa_2)^{-k} \sup_{m,n} |f_{mn}| \sum_{m, n \geq 0} c_{m,n+k}(\kappa_1)^m(\kappa_2)^{n+k} |v_{m,n+k}| \|_v \\
\leq (\kappa_2)^{-k} \sup_{m,n} |f_{mn}| \|v\|_v
\]

32
Here $c_{mn} \leq c_{m,n+k}$ for all $m, n, k \geq 0$ has been used. Now

$$
\|V[k, f]\|_{V \rightarrow V} = \| \sum_{L=0}^{\infty} U[kL, fL]\|_{V \rightarrow V} \\
\leq \sum_{L=0}^{\infty} \|U[kL, fL]\|_{V \rightarrow V} \\
\leq \sum_{L=0}^{\infty} C_{fL}(\kappa_2)^{-kL} \sup_{m,n} |(fL)_{mn}| \\
\leq C_f(1 - (\kappa_2)^{-1})^{-1}
$$

with $(f_L)_{mn} = (-1)^L \prod_{\ell=0}^{L-1} f_{m,n+\ell}$. Here $C_{fL} \leq C_f$ and $|(f_L)_{mn}| \leq 1$ have been used.

Estimate for $S_{\Gamma_1}$. By (35),

$$
\|S_{\Gamma_1}\|_{V \rightarrow V} \leq 4 \|U_{1,1} V_{2,1}\|_{V \rightarrow V} \leq K_1 \overset{\text{def}}{=} 4(\kappa_2)^{-1}(1 - (\kappa_2)^{-2})^{-1} \quad (36)
$$

To check this, note that the first component of $S_{\Gamma_1} v$ vanishes, for all $v \in V$.

Auxiliary estimates for $U^{-1} \star$. By (35),

$$
\|J^{-1}_{\mu_{\text{refA}}} v\|_{V \rightarrow V} \leq \max\{\|K^{-1}_{\mu_{\text{refA}}} v\|_{V \rightarrow V}, \|J^{-1}_{\mu_{\text{refA}}} v\|_{V \rightarrow V}\} \\
\leq K_2 \overset{\text{def}}{=} 2 \mu_{\text{refA}}^{-1}(1 - (\kappa_2)^{-1})^{-1}(1 + (\kappa_2)^{-1})^{-1} \quad (37a) \\
\|J^{-1}_{\mu_{\text{refA}}} J\|_{V \rightarrow V} \leq K_2 \quad (37b)
$$

For (37), note that

$$(1 - (\kappa_2)^{-2})^{-1}(1 + (\kappa_2)^{-2}) \leq (1 - (\kappa_2)^{-1})^{-1}(1 + (\kappa_2)^{-1}) \quad (38)$$

For (37b), note that $J^{-1}_{\mu} J = \mu^{-1} V[1, f](U[0, \frac{\mu(n+1)}{im/2+\mu(n+1)}] + U[1, \frac{\mu}{im/2+\mu(n+1)}])$ for some $f$ with $|f_{mn}| \leq 1$. Similar for $K^{-1}_{\mu} K$.

Suppose $U$ is invertible. Fix an invertible linear operator $A : V \rightarrow V$ with $A = sA + (1 - s) \overset{\text{def}}{=} A_0$. (The operator $A$ is only introduced for an important operator norm estimate of the form $\|O_1 O_2\| \leq ||O_1 A^{-1}||\|A O_2\|$, to improve over the naive $\leq ||O_1||\|O_2\|$. See the left hand sides of (39d) and
(39e) below.) Fix constants $0 < L_1, \ldots, L_6 < \infty$. Suppose
\[ \| S \Xi^\top (\omega_\text{refA}, \cdot) \| V_{\rightarrow} \leq L_1 \]  
\[ \| \omega_\text{refB} \| V \leq L_2 \]  
\[ \| S \Omega^+ (\mu_\text{ref}, \omega_\text{ref}) \| V \leq L_3 \]  
\[ \| \mathfrak{A} J^{-1} (A - s A s) \| V_{\rightarrow} \leq L_4 \]  
\[ \| U^{-1} \mathfrak{A}^{-1} \| R \otimes V_{\rightarrow} \leq L_5 \]  
\[ \| U^{-1} \| R \otimes V_{\rightarrow} \leq L_6 \]  

Then (this estimate is used only in Section 4.1)
\[ \| A \| V_{\rightarrow} \leq K_3 \overset{\text{def}}{=} \mu_\text{refA} K_1 + 2 L_1 \]

Fix constants $0 < S_1, \ldots, S_5 < \infty$. Suppose
\[ L_6 K_2 L_3 \leq S_1 \]  
\[ L_6 K_2 (1 + K_1) L_2 / \kappa_* \leq S_2 \]  
\[ L_6 K_2 (\mu_\text{refB} + \mu_\text{refB} K_1 + 6 L_2) + L_5 L_4 \leq S_3 \]  
\[ L_6 K_2 (1 + K_1) / \kappa_* \leq S_4 \]  
\[ 3 L_6 K_2 \leq S_5 \]  

Set $S_{23} = \max\{S_2, S_3\}$ and $S_{45} = \max\{S_4, 2 S_5\}$.

**Estimates for** $U^{-1}\mathbf{\star}$. We have
\[ \| U^{-1} \mathbf{\star} (\lambda, v) \| R \otimes V \leq S_1 + S_2 \kappa_* |\lambda| + S_3 \| v \| V + S_4 \kappa_* |\lambda| \| v \| V + S_5 (\| v \| V)^2 \]
\[ \leq S_1 + S_{23} \| \lambda \oplus v \| R \otimes V + \frac{1}{2} S_{45} (\| \lambda \oplus v \| R \otimes V)^2 \]  
\[ \leq \left( S_{23} + \frac{1}{2} S_{45} (\| \lambda_1 \oplus v_1 \| R \otimes V + \| \lambda_2 \oplus v_2 \| R \otimes V) \right) \| \lambda_1 \oplus v_1 - \lambda_2 \oplus v_2 \| R \otimes V \]

**Solution to** $S \Omega^+ (\mu, \omega) = 0$. Fix a constant $R > 0$. Suppose
\[ S_1 + S_{23} R + \frac{1}{2} S_{45} R^2 \leq R \]
\[ S_{23} + S_{45} R < 1 \]
\[ R < \kappa_* \mu_\text{ref} \]
Rearranging the $\star$ system. Introduce $A^\sharp, \mathbb{U}^\sharp, \star^\sharp : \mathcal{V}^\sharp \to \mathcal{V}^\sharp$ linear maps
\begin{align*}
A^\sharp &= \mu_{\text{refA}} \Xi^{-1,\text{reg}} \Gamma_1^\sharp + \Gamma_2^\sharp (\omega_{\text{refA}}, \cdot) \\
\mathbb{U}^\sharp &= 1 + (J^\sharp_{\text{refA}})^{-1} S A^\sharp s \\
\star^\sharp &= -(J^\sharp_{\text{refA}})^{-1} \{(\mu_{\text{refB}} + \mu_{\text{corr}})(A^\sharp + \Xi^{-1,\text{reg}} \Gamma_1^\sharp) + \Gamma_2^\sharp (\omega_{\text{refB}} + \omega_{\text{corr}}, \cdot)\} \\
&\quad - (J^\sharp_{\text{refA}})^{-1} (A^\sharp - s A^\sharp s) \\
\end{align*}
Here, $s = \text{diag}(s, s) : \mathcal{V}^\sharp \to \mathcal{V}^\sharp$. This is an abuse of notation, but it will always be clear if $s : \mathcal{V} \to \mathcal{V}$ or $s : \mathcal{V}^\sharp \to \mathcal{V}^\sharp$. Since $(\mu, \omega)$ is now a solution to $S \Omega^+(\mu, \omega) = 0$, it follows from (26) and the construction (45) that
\begin{equation}
\mathbb{U}^\sharp \omega^\sharp = \star^\sharp \omega^\sharp 
\end{equation}
Note that $\mathbb{U}^\sharp = s \mathbb{U}^\sharp s + (1 - s)$. Therefore, $\mathbb{U}^\sharp$ is invertible if and only if the finite square matrix $s \mathbb{U}^\sharp s : \text{image } s \to \text{image } s$ is invertible.

Norm on (a subspace of) $\mathcal{V}^\sharp$. Set $\|w\|_{\mathcal{V}^\sharp} = \|w_1\|_{\mathcal{V}} + \|w_2\|_{\mathcal{V}}$ for all $w = (w_1, w_2) \in \mathcal{V}^\sharp$. This is a norm on $\{w \in \mathcal{V}^\sharp | \|w\|_{\mathcal{V}^\sharp} < \infty\} \subset \mathcal{V}^\sharp$.

Estimate for $\Gamma_2^\sharp$.
\begin{equation}
\|\Gamma_2^\sharp (v, \cdot)\|_{\mathcal{V}^\sharp} \leq \max \left\{ \| \frac{1}{2} \begin{pmatrix} v_2 + P v_2 - P v_3 - v_3 \\ v_1 - v_2 + P v_1 \\ -v_1 + P v_3 - v_3 \\ -v_1 + v_2 + 3 P v_2 \end{pmatrix} \|_{\mathcal{V}^\sharp}, \| \frac{1}{2} \begin{pmatrix} v_2 + P v_2 + P v_3 + v_3 \\ -v_1 + v_2 + 3 P v_2 \end{pmatrix} \|_{\mathcal{V}^\sharp} \right\} 
\end{equation}
Auxiliary estimates for \((\mathbb{U}^\sharp)^{-1}\star\). We have
\[
\begin{aligned}
\|\Gamma_2^\sharp(\nu, \cdot)\|_{\nu_\rho + \nu_\rho} &\leq 3\|\nu\|_{\nu} \\
\|\Xi^{-1,\text{reg}}\Gamma_1^\sharp\|_{\nu_\rho + \nu_\rho} &\leq K_1^\sharp \equiv 2(\kappa_2)^{-1}(1 - (\kappa_2)^{-2})^{-1} \\
\|(J_{\mu_{\text{ref}}}^\sharp)^{-1}\|_{\nu_\rho + \nu_\rho} &\leq K_2^\sharp \equiv 2\mu_{\text{ref}}^{-1}(1 - (\kappa_2)^{-1})^{-1}(1 + (\kappa_2)^{-1})
\end{aligned}
\]
Suppose \(\mathbb{U}^\sharp\) is invertible. Fix an invertible linear operator \(A^\sharp : \nu_\rho \to \nu_\rho\) with \(A^\sharp = sA^\sharp s + (1 - s)\). Fix \(0 < L_1^\sharp, L_2^\sharp, L_3^\sharp, L_4^\sharp, L_5^\sharp < \infty\). Suppose
\[
\begin{aligned}
\|\Gamma_2^\sharp(\omega_{\text{ref}}, \cdot)\|_{\nu_\rho + \nu_\rho} &\leq L_1^\sharp \quad (48a) \\
\|\omega_{\text{ref}} + \omega_{\text{corr}}\|_{\nu} &\leq L_2^\sharp \quad (48b) \\
\|A^\sharp(J_{\mu_{\text{ref}}}^\sharp)^{-1}(A^\sharp - sA^\sharp s)\|_{\nu_\rho + \nu_\rho} &\leq L_3^\sharp \quad (48c) \\
\|(\mathbb{U}^\sharp)^{-1}(A^\sharp)^{-1}\|_{\nu_\rho + \nu_\rho} &\leq L_4^\sharp \quad (48d) \\
\|(\mathbb{U}^\sharp)^{-1}\|_{\nu_\rho + \nu_\rho} &\leq L_5^\sharp \quad (48e)
\end{aligned}
\]
Then
\[
\|A^\sharp\|_{\nu_\rho + \nu_\rho} \leq K_3^\sharp \equiv \mu_{\text{ref}}K_1^\sharp + L_1^\sharp
\]

Estimate for \((\mathbb{U}^\sharp)^{-1}\star\).
\[
\|(\mathbb{U}^\sharp)^{-1}\star\|_{\nu_\rho + \nu_\rho} \leq |\mu_{\text{ref}} + \mu_{\text{corr}}|L_3^\sharp K_2^\sharp(1 + K_1^\sharp) + 3L_3^\sharp K_2^\sharp L_2^\sharp + L_4^\sharp L_5^\sharp \quad (49)
\]

Suppose the right hand side of (49) is < 1. Then \((\mathbb{U}^\sharp)^{-1}\star\|_{\nu_\rho + \nu_\rho} < 1\). We show that this implies \(\omega^\sharp = 0\), i.e. that \((\mu, \omega)\) solves \textbf{2DProbSeries}.

The claim seems to follow from (46), which yields \((1 - ||O||_{\nu_\rho + \nu_\rho})\|\omega^\sharp\|_{\nu_\rho} \leq 0\) with \(O = (\mathbb{U}^\sharp)^{-1}\star\), and which seems to imply that \(\|\omega^\sharp\|_{\nu_\rho}\) must vanish. This reasoning is invalid, because \(\|\omega^\sharp\|_{\nu_\rho}\) is not known to be finite. We have to work a little more.

For every \(\nu\) with \(1/\kappa_1, 1/\kappa_2 < \nu \leq 1\), set:
\[
\|v\|_{(\nu,\nu)} = \sum_{m,n \geq 0}(2 - \delta_{m0})(2 - \delta_{n0})(\nu\kappa_1)^m(\nu\kappa_2)^n\|v_{mn}\|_C
\]
Define \(\|\cdot\|_{(\nu,\nu)}\) and \(\|\cdot\|_{[(\nu,\nu)]}\) accordingly. Note that \(\|\cdot\|_{(\nu,1)} = \|\cdot\|_{\nu}\). If \(\nu < 1\), then (43) implies \(\|\omega^\sharp\|_{(\nu_\rho,\nu_\rho)} < \infty\). Therefore, if we can show that \(\|O\|_{(\nu_\rho,\nu_\rho)\to(\nu_\rho,\nu_\rho)} < 1\) for some \(\nu < 1\), then \(\omega^\sharp\) vanishes. Since \(\|O\|_{(\nu_\rho,\nu_\rho)} < 1\) by assumption, it suffices to prove
\[
\limsup_{\nu \downarrow 1} \|O\|_{(\nu_\rho,\nu_\rho)\to(\nu_\rho,\nu_\rho)} \leq \|O\|_{\nu_\rho + \nu_\rho} \quad (50)
\]
To check this, let $e = (e_1, e_2) \in \mathbf{V}^j$ be a unit vector, i.e. there are $d(e) \in \{1, 2\}$ and $k(e) \in \{0, 1\}$ and $m(e), n(e) \geq 0$ such that $(e_{d(e)})_{m(e), n(e)} = 1$ if $k(e) = 0$ and $(e_{d(e)})_{m(e), n(e)} = i$ if $k(e) = 1$, and all other components of $e$ are zero. Unit vectors are useful, because

$$\|O\|_{(\mathbf{V}^j, \nu) \to (\mathbf{V}^j, \nu)} = \sup_{\text{unit vector } e} \frac{\|Oe\|_{(\mathbf{V}^j, \nu)}}{\|e\|_{(\mathbf{V}^j, \nu)}} \quad \text{(if the left hand side is } \leq \infty)$$

This is a special property of the $\ell^1$ operator norm. Fix a unit vector $e$. For $N \geq 0$, decompose $Oe = (Oe)^{N+} + (Oe)^{N-}$ with $(Oe)^{N+}, (Oe)^{N-} \in \mathbf{V}^j$ and

$$d \in \{1, 2\}, \quad m, n \geq 0 : \quad ((Oe)^{d\pm})_{mn} = \begin{cases} ((Oe)_d)_{mn} & \text{if } m + n > m(e) + n(e) - N \\ 0 & \text{otherwise} \end{cases}$$

Suppose $\nu_0, \nu$ satisfy $\{1/\kappa_1, 1/\kappa_2\} < \nu_0 < \nu < 1$. Then

$$\|Oe\|_{(\mathbf{V}^j, \nu)} \leq \|(Oe)^{N+}\|_{(\mathbf{V}^j, \nu)} + \|(Oe)^{N-}\|_{(\mathbf{V}^j, \nu)}$$

$$\leq \nu^{m(e)+n(e)-N} \|(Oe)^{N+}\|_{\mathbf{V}^j} + \left(\nu/\nu_0\right)^{m(e)+n(e)-N} \|(Oe)^{N-}\|_{(\mathbf{V}^j, \nu_0)}$$

Since $\|e\|_{(\mathbf{V}^j, \nu)} = \nu^{m(e)+n(e)} \|e\|_{\mathbf{V}^j} = \left(\nu/\nu_0\right)^{m(e)+n(e)} \|e\|_{(\mathbf{V}^j, \nu_0)}$, it follows that

$$\frac{\|Oe\|_{(\mathbf{V}^j, \nu)} \|e\|_{(\mathbf{V}^j, \nu)}}{\|\nu\|_{(\mathbf{V}^j, \nu)}} \leq \nu^{-N} \|Oe\|_{\mathbf{V}^j} + \left(\nu/\nu_0\right)^{-N} \|Oe\|_{(\mathbf{V}^j, \nu)}$$

Since this holds for all $e$, and since $\|O\|_{(\mathbf{V}^j, \nu) \to (\mathbf{V}^j, \nu)} < \infty$ (see the remark below),

$$\|O\|_{(\mathbf{V}^j, \nu) \to (\mathbf{V}^j, \nu)} \leq \nu^{-N} \|O\|_{\mathbf{V}^j} + \left(\nu/\nu_0\right)^{-N} \|O\|_{(\mathbf{V}^j, \nu)}$$

Fix $\nu_0$, set $N(\nu) = (1 - \nu)^{-1/2}$ and let $\nu \uparrow 1$. Then $\nu^{-N(\nu)} \to 1$ and $(\nu/\nu_0)^{-N(\nu)} \to 0$, and inequality (50) follows, because $\|O\|_{(\mathbf{V}^j, \nu_0) \to (\mathbf{V}^j, \nu_0)} < \infty$ (see the remark below).

**Remark:** We show that $\|O\|_{(\mathbf{V}^j, \nu) \to (\mathbf{V}^j, \nu)} < \infty$ if $\max\{1/\kappa_1, 1/\kappa_2\} < \nu \leq 1$. Separately,

$$\|\mathbf{1}^j\|_{(\mathbf{V}^j, \nu) \to (\mathbf{V}^j, \nu)} < \infty \quad \|\mathbf{\Phi}^j\|_{(\mathbf{V}^j, \nu) \to (\mathbf{V}^j, \nu)} < \infty$$

The first by $\{\mathbf{1}^j\}^{-1} = \mathbf{s}(\mathbf{1}^j)^{-1} \mathbf{s} + (1 - \mathbf{s})$. The second by direct inspection of (45), using $\|\omega_{\text{refA}}\|_{(\mathbf{V}^j, \nu)} \leq \|\omega_{\text{refA}}\|_{\mathbf{V} \nu} \leq \|\omega_{\text{refB}} + \omega_{\text{corr}}\|_{(\mathbf{V}^j, \nu)} \leq \|\omega_{\text{refB}} + \omega_{\text{corr}}\|_{\mathbf{V} \nu} < \infty$, see (43), and $\|(\mathbf{J}^j)_{\text{refA}}\|_{(\mathbf{V}^j, \nu) \to (\mathbf{V}^j, \nu)} < \infty$, among others.

### 4.1 Exterior estimates: (39d) and (48c)

Fix cutoff operators $t$, $q$ similar to $s$. Suppose

$$2 \leq m(s) \leq m(q) \leq m(t) - m(s) + 1 \leq m(t) \quad \text{and} \quad 1 \leq n(s) \leq n(q) \leq n(t) - n(s) + 1 \leq n(t)$$

### 4.1.1 Exterior estimates: (39d) and (48c)

Fix cutoff operators $t$, $q$ similar to $s$. Suppose

$$2 \leq m(s) \leq m(q) \leq m(t) - m(s) + 1 \leq m(t) \quad \text{and} \quad 1 \leq n(s) \leq n(q) \leq n(t) - n(s) + 1 \leq n(t)$$
and $3 \leq n(q)$. It follows that $sq = qs = s$ and $qt = tq = q$ and $st = ts = s$. For convolution, $q((\bar{t} \cdot (s \cdot )) = 0$ and $qS\Xi\Gamma_2(\bar{t} \cdot , s \cdot ) = 0$, where a dot is any argument. In this section only, we abbreviate

\[ \bar{s} = 1 - s, \quad \bar{s} = 1 - s, \quad \text{etc} \quad \text{(the bar is not for complex conjugation)} \]

For every linear operator $O : \mathbf{V} \to \mathbf{V}$, the $\ell^1$ operator norm satisfies

\[ \|O\|_{\mathbf{V} \to \mathbf{V}} = \max \{ \|Ot\|_{\mathbf{V} \to \mathbf{V}}, \|Ot\|_{\mathbf{V} \to \mathbf{V}} \} \]

Similar for $\mathbf{V}^\ast$. Suppose the $t$ parts in (39d), (48c) are under control:

\[ \|\mathfrak{A}J^{-1}_{\mu_{\text{refA}}}(A - sAs)t\|_{\mathbf{V} \to \mathbf{V}} \leq \mathcal{L}_4 \]  \hspace{1cm} (52a)
\[ \|\mathfrak{A}^t(J^t_{\mu_{\text{refA}}}^{-1})(A^t - sA^t)t\|_{\mathbf{V}^\ast \to \mathbf{V}^\ast} \leq \mathcal{L}_3^t \]  \hspace{1cm} (52b)

Suppose that in addition,

\[ \|\mathfrak{A}\|_{\mathbf{V} \to \mathbf{V}}(\mathcal{M}_2\mathcal{M}_1 + \mathcal{M}_2\mathcal{K}_3) + \mathcal{M}_3\mathcal{K}_3 \leq \mathcal{L}_4 \]  \hspace{1cm} (52c)
\[ \|\mathfrak{A}^t\|_{\mathbf{V}^\ast \to \mathbf{V}^\ast}(\mathcal{M}_2^t\mathcal{M}_1 + \mathcal{M}_2\mathcal{K}_3^t) + \mathcal{M}_3^t\mathcal{K}_3^t \leq \mathcal{L}_3^t \]  \hspace{1cm} (52d)

with

\[ \mathcal{M}_1 = 4\mu_{\text{refA}}(\kappa_2)^{-\left(n(t) - n(q) + 1\right)}(1 - (\kappa_2)^{-1})^{-1} \]
\[ \mathcal{M}_2 = 4\mu_{\text{refA}}^{-1}(\kappa_2)^{-\left(n(q) - n(s) + 1\right)}(1 - (\kappa_2)^{-1})^{-1} \]
\[ \mathcal{M}_3 = 2(1 - (\kappa_2)^{-1})^{-1}\max\left\{2(m(q))^{-1}, \mu_{\text{refA}}^{-1}(n(q) - 1)^{-1}\right\}(1 + (\kappa_2)^{-1}) \]

In the rest of this section, we show that (52c), (52d) control the $\bar{t}$ parts. In other words, we show that (52) implies (39d), (48c).

For (52c), set $O = \mathfrak{A}J^{-1}_{\mu_{\text{refA}}}(A - sAs)$, a local notation. Since $s\bar{t} = 0$, one has

\[ O\bar{t} = \mathfrak{A}J^{-1}_{\mu_{\text{refA}}} A\bar{t} = (s\mathfrak{A}s + \bar{s}) J^{-1}_{\mu_{\text{refA}}} \left(q + \bar{q}\right) A\bar{t} = \mathfrak{A}J^{-1}_{\mu_{\text{refA}}} qA\bar{t} + s\mathfrak{A}s J^{-1}_{\mu_{\text{refA}}} \bar{q}A\bar{t} + \bar{s} J^{-1}_{\mu_{\text{refA}}} \bar{q}A\bar{t} \]

It follows that

\[ \|O\bar{t}\| \leq \|\mathfrak{A}\| \|J^{-1}_{\mu_{\text{refA}}} \| + \|q\| A\bar{t} \| + \|s\| J^{-1}_{\mu_{\text{refA}}} \bar{q} \| A\bar{t} \| + \|J^{-1}_{\mu_{\text{refA}}} \bar{q} \| A\bar{t} \| \]

38
with $\| \cdot \| = \| \cdot \|_{\mathbf{v}^* - \mathbf{v}}$, a local notation. Recall (28). We have
\[
\| q A \| = \mu_{\text{refA}} \| q S_1 \| \leq \mu_{\text{refA}} 4 \| q \| V_{1,1} V_{2,1} \| \mathbf{v}^* - \mathbf{v} \leq M_1
\]
\[
\| s J_{\text{refA}}^{-1} q \| \leq \max \{ \| s J_{\text{refA}}^{-1} \| \| \mathbf{v}^* - \mathbf{v} \| , \| s K_{\text{refA}}^{-1} \| \| \mathbf{v}^* - \mathbf{v} \| \} \leq M_2
\]
\[
\| J_{\text{refA}}^{-1} q \| \leq \max \{ \| J_{\text{refA}}^{-1} \| \| \mathbf{v}^* - \mathbf{v} \| , \| K_{\text{refA}}^{-1} \| \| \mathbf{v}^* - \mathbf{v} \| \} \leq M_3
\]
Therefore, (52c) implies $\| O \| \leq L_4$, as required.

In (A), we estimate $\| s J_{\text{refA}}^{-1} \| \| \mathbf{v}^* - \mathbf{v} \|$. Similar for $\| s K_{\text{refA}}^{-1} \| \| \mathbf{v}^* - \mathbf{v} \|$. In (B) we estimate $\| K_{\text{refA}}^{-1} \| \| \mathbf{v}^* - \mathbf{v} \|$. Similar for $\| J_{\text{refA}}^{-1} \| \| \mathbf{v}^* - \mathbf{v} \|$.

(A) There are numbers $Q_{mn} \in \mathbb{C}$ such that $(s J_{\text{refA}}^{-1} q)_{mn} = \sum_{n' \geq 0} Q_{mn} v_{mn'}$ for all $v \in \mathcal{V}$, and $\| Q_{mn} \|_{\mathbb{C}} \leq 4 \mu_{\text{refA}}$. Also
\[
Q_{mn} \neq 0 \quad \Rightarrow \quad (m < m(s)) \text{ and } (n < n(s)) \quad \text{and} \quad (m = m(q)) \text{ or } (n = n(q))
\]
Since $m(s) \leq m(q)$, this simplifies to
\[
Q_{mn} \neq 0 \quad \Rightarrow \quad (m < m(s)) \quad \text{and} \quad (n < n(s)) \quad \text{and} \quad (n \geq n(q))
\]
Therefore, with $c_m = (2 - \delta_{m0})(2 - \delta_{m0})$,
\[
\| s J_{\text{refA}}^{-1} \| \| \mathbf{v} \| = \sum_{m,n \geq 0} c_{mn} (\kappa_1)^m (\kappa_2)^n \| \sum_{n' \geq 0} Q_{mn} v_{mn'} \|_{\mathbb{C}}
\]
\[
= \sum_{0 \leq m < m(s), 0 \leq n < n(s)} c_{mn} (\kappa_1)^m (\kappa_2)^n \| \sum_{n' \geq n(q)} Q_{mn} v_{mn'} \|_{\mathbb{C}}
\]
\[
\leq 4 \mu_{\text{refA}} \| \sum_{0 \leq m < m(s), 0 \leq n < n(s)} c_{mn} (\kappa_1)^m (\kappa_2)^n \| v_{mn} \|_{\mathbb{C}}
\]
\[
\leq 4 \mu_{\text{refA}} \| \sum_{0 \leq m < m(s), n' \geq n(q)} c_{mn} (\kappa_1)^m (\kappa_2)^n \| v_{mn} \|_{\mathbb{C}} \| \sum_{0 \leq n < n(s)} (\kappa_2)^{n-n'}
\]
\[
\leq 4 \mu_{\text{refA}} \| v \| v_{mn} \|_{\mathbb{C}} \| \sum_{0 \leq n < n(s)} (\kappa_2)^{n-n(q)}
\]
\[
\leq 4 \mu_{\text{refA}} \| v \| v_{mn} \|_{\mathbb{C}} \| \sum_{0 \leq n < n(s)} (\kappa_2)^{n-n(q)} \| (1 - (\kappa_2)^{-1})^{-1}
\]
Here $c_{mn} \leq c_{mn}$ has been used in one step.

(B) Let $r$ be the cutoff with $m(r) = m(q)$ and $n(r) = n(q) - 2$, a local notation. Then $K_{\text{refA}}^{-1} q = V[2, f] L_{\text{refA}}^{-1} (1 + U_{2,1}) q = V[2, f] L_{\text{refA}}^{-1} (1 + U_{2,1}) q$ for some $f$. Therefore,
\[
\| K_{\text{refA}}^{-1} \| \| \mathbf{v}^* - \mathbf{v} \| \leq \| V[2, f] \| \| \mathbf{v}^* - \mathbf{v} \| \| L_{\text{refA}}^{-1} \| \| \mathbf{v}^* - \mathbf{v} \| \leq 1 + \| U_{2,1} \| \| \mathbf{v}^* - \mathbf{v} \|
\]
Use $\| V[2, f] \| \| \mathbf{v}^* - \mathbf{v} \| \leq \sqrt{2}(1 - (\kappa_2)^{-2})^{-1}$ and $1 + \| U_{2,1} \| \| \mathbf{v}^* - \mathbf{v} \| \leq 1 + (\kappa_2)^{-2}$ and
\[
\| L_{\text{refA}}^{-1} \| \| \mathbf{v}^* - \mathbf{v} \| \leq \sqrt{2} \sup_{\text{sec below}} \frac{1}{|m/2 + \mu_{\text{refA}}(n + 1)|} \leq \sqrt{2} \max \left\{ \frac{2}{m(q)}, \frac{1}{\mu_{\text{refA}}(n(q) - 1)} \right\}
\]
where the sup is over all $m, n \geq 0$ with $m \geq m(q)$ or $n \geq n(q) - 2$. Now use (38).
For (52d), set $O^\sharp = 2\xi (J^\sharp_{\mu_{\text{refA}}})^{-1}(A^\sharp - sA^\sharp s)$. Then

$$
\|O^\sharp \bar{t}\| \leq \|2\xi\| \| (J^\sharp_{\mu_{\text{refA}}})^{-1} \| \| qA^\sharp \bar{t}\| + \|2\xi\| \| s(J^\sharp_{\mu_{\text{refA}}})^{-1}q \| \| A^\sharp\| \\
+ \|(J^\sharp_{\mu_{\text{refA}}})^{-1}q \| \| A^\sharp\|
$$

with $\| \cdot \| = \| \cdot \|_{V^\sharp - V^\sharp}$. Recall (28). One has

$$
\| qA^\sharp \bar{t}\| = \mu_{\text{refA}} \|q \Xi^{-1, \text{reg}} \Gamma_{\bar{t}}^\sharp\| \leq \mu_{\text{refA}} 2 \|q U_{1,1} V_{2,1} \bar{t}\|_{\nu^\nu - \nu^\nu} \leq M_1 \\
\| s(J^\sharp_{\mu_{\text{refA}}})^{-1}q\| \leq M_2 \\
\| (J^\sharp_{\mu_{\text{refA}}})^{-1}q\| \leq M_3
$$

Therefore, (52d) implies $\|O^\sharp \bar{t}\| \leq \mathcal{L}^\sharp_3$, as required.

### 5 Parameter values and Computer assisted results

This section takes care of every individual ♣ tag in Section 4. Set

$$
\kappa_1 = \frac{65}{64} \quad \kappa_2 = \frac{5}{4} \quad \kappa_3 = 1 \quad m(s) = 250 \quad m(t) = 1600 \quad m(q) = 1350 \quad n(s) = 750 \quad n(t) = 4800 \quad n(q) = 4050
$$

We have ♣1 ✔ ♣6 ✔ ♣7 ✔ ♣36 ✔ ♣37 ✔ ♣38 ✔ ♣39 ✔. The text files RefA.dat and RefAplusB.dat contain $(\mu_{\text{refA}}, \omega_{\text{refA}})$ and $(\mu_{\text{refA}} + \mu_{\text{refB}}, \omega_{\text{refA}} + \omega_{\text{refB}})$; the file format is self-explanatory from the discussion in Section 6 ♣2 ✔ ♣3 ✔ ♣4 ✔ ♣5 ✔. One finds, either by looking at the first few lines of these files, or with the command choptuik LoadAplusB:

$$
\mu_{\text{refA}} = 722873400 \cdot 2^{-32} \\
\mu_{\text{refA}} + \mu_{\text{refB}} = 786320438575298\ldots 180 \text{ final digits omitted \ldots} \cdot 2^{-650} ♣
$$

Most readers should ignore the ♣ tags. (They tag the things that must be revisited if one repeats the construction with a different refB, but the same refA, to get a better approximation to Choptuik’s solution.) Set

$$
\mathcal{L}_1 = 10.5 \quad \mathcal{L}_2 = 2^{-25} ♣ \quad \mathcal{L}_3 = 2^{-294} ♣ \\
\mathcal{L}_4 = 0.625 \quad \mathcal{L}_5 = 1.004 \quad \mathcal{L}_6 = 258 \\
\mathcal{S}_1 = 2^{-279} ♣ \quad \mathcal{S}_2 = 0.01 ♣ \quad \mathcal{S}_3 = 0.64 ♣ \\
\mathcal{S}_4 = 2^{19} \quad \mathcal{S}_5 = 2^{17} \\
\mathcal{L}^\sharp_1 = 8 \quad \mathcal{L}^\sharp_2 = 2^{-25} ♣ \\
\mathcal{L}^\sharp_3 = 0.625 \quad \mathcal{L}^\sharp_4 = 1.004 \quad \mathcal{L}^\sharp_5 = 258
$$

40
Set $\mathbf{A} = \text{diag}(\mathbf{B}, \mathbf{B}, \mathbf{B}, \mathbf{B})$ and $\mathbf{A}^\sharp = \text{diag}(\mathbf{B}, \mathbf{B})$ where

$$(\mathbf{B}v)_{mn} = \begin{cases} 256v_{mn} & \text{if } m < 50 \text{ and } n < 150 \\ 16v_{mn} & \text{else, if } m < 100 \text{ and } n < 300 \\ 4v_{mn} & \text{else, if } m < 150 \text{ and } n < 450 \\ 2v_{mn} & \text{else, if } m < 200 \text{ and } n < 600 \\ 1.5625v_{mn} & \text{else, if } m < 250 \text{ and } n < 750 \\ v_{mn} & \text{else} \end{cases}$$

in particular, $\mathbf{B} = s\mathbf{B}_5 + (1 - s)$ in particular, $\mathbf{B} = s\mathbf{B}_5 + (1 - s)$. It follows that

$$K_1 = \frac{80}{9}, \quad S_{23} = 0.64, \quad S_{45} = 2^{19}, \quad K_1^\sharp = \frac{40}{9}, \quad K_2^\sharp \leq 107, \quad K_2^\sharp \leq 22.5, \quad K_3^\sharp \leq 8.75, \quad K_3^\sharp \leq 0.027$$

$$\|\mathbf{A}\|_{\mathcal{V}_{\mathcal{V}}} \leq 256, \quad \|\mathbf{A}^\sharp\|_{\mathcal{V}_{\mathcal{V}}} \leq 256$$

Now

(39a): Use (33) with $v = \omega_{\text{refA}}$. Use choptuik DedicatedGAMMA2.

(39b): Use choptuik LoadAplusB.

(39c): Use choptuik FailureToBeSolAplusB. One output line is

$$(11 \text{ norm of } S\mathbf{B}(\text{OmegaPlus}(\text{refAplusB}))) \leq 15312135*2^{-320}$$

(This command requires $\sim 16$ GB RAM.) This takes care of.

We note that the command choptuik FailureToBeSolAplusB also yields

$$(11 \text{ norm of } \text{OmegaPlus}(\text{refAplusB})) \leq 24707998*2^{-320}$$

which includes the constraint equations. We don’t need this inequality.

For (39d), note that (52c) holds. To check (52a) use the command

```
choptuik EXTERIOR_ESTIMATE offm_offn_numm_numn
```

(53)

where $\text{offm}_m, \text{offn}_n, \text{numm}_m, \text{numn}_n$ have to be replaced by actual numbers that satisfy $\text{offm}_m, \text{offn}_n \geq 0$ and $\text{numm}_m, \text{numn}_n > 0$ and $\text{offm}_m + \text{numm}_m \leq m(t)$ and $\text{offn}_n + \text{numn}_n \leq n(t)$. For example, an actual command would be
The command (53) generates a file with a number of lines, one line for each unit vector in $\mathbf{V}$ whose Fourier-Chebyshev indices $(m, n)$ satisfy $\text{off}m \leq m < \text{off}m + \text{num}m$ and $\text{off}n \leq n < \text{off}n + \text{num}n$. Each line begins with $d_{k_m,n}$, for the unit vector $e = (e_1, e_2, e_3, e_4) \in \mathbf{V}$ with $(e_{d+1})_{mn} = 1$ if $k = 0$, and $(e_{d+1})_{mn} = i$ if $k = 1$, all other entries equal to zero. For example, the line

1.0_212_750 550*2^{-10} TRUE

for the unit vector $(e_2)_{212,750} = 1$ asserts that

$$\|\mathbf{A} \mathbf{J}^{-1} \mathbf{P}_{\text{refA}} (A - s \mathbf{A}s) \mathbf{e}\|_{\mathbf{V}} / \|\mathbf{e}\|_{\mathbf{V}} \leq 550 \cdot 2^{-10}$$

(55)

The TRUE indicates that this number is $\leq 0.625$, as required by (52a).

The file EXTERIOR_ESTIMATE_0_0_1600_4800.dat was generated on an HPC cluster, and contains the result of applying (53) to all 26868000 unit vectors in image $\mathbf{t} \subset \mathbf{V}$. Many tools can be used to analyze the file. For example, every line of the file has the same structure as (54), because the unix command

`grep -v -c '^0123_[01]_[0-9]*_[0-9]* [0-9]*2\^(-10) TRUE $' EXTERIOR_ESTIMATE_0_0_1600_4800.dat`

yields 0. Without the -v option, it yields 26868000.

For (39e) and (39f), use the command

`choptuik INV offm_offn_numm_numn`

(56)

with $\text{off}m + \text{num}m \leq m(\mathbf{s})$ and $\text{off}n + \text{num}n \leq n(\mathbf{s})$ (more details below). It shows that there exists a linear map $\mathbf{V} : \mathbf{V} \rightarrow \mathbb{R} \oplus \mathbf{V}_{\text{Gauged}}$, block diagonal with respect to the decomposition (cf. (32))

$$(\text{image} \mathbf{s}) \oplus (\text{image}(1 - \mathbf{s})) \rightarrow (\mathbb{R} \oplus (\mathbf{V}_{\text{Gauged}} \cap \text{image} \mathbf{s})) \oplus \text{image}(1 - \mathbf{s})$$

such that the high-to-high frequency block $\text{image}(1 - \mathbf{s}) \rightarrow \text{image}(1 - \mathbf{s})$ is the identity, and such that

$$\|1 - \mathbf{U} \mathbf{V}\|_{\mathbf{V} \rightarrow \mathbf{V}} \leq 2^{-16} \quad \|\mathbf{V} \mathbf{A}^{-1}\|_{\mathbb{R} \oplus \mathbf{V} \rightarrow \mathbf{V}} \leq 1$$

(57)

(The operator $\mathbf{A}$ was constructed so that the second inequality would hold.) It follows that $\mathbf{U}$ is invertible, and given in terms of the Neumann series

$$\mathbf{U}^{-1} = \mathbf{V} \frac{1}{1 - (1 - \mathbf{U} \mathbf{V})} \quad \text{or} \quad \mathbf{U}^{-1} = \mathbf{V} \mathbf{A}^{-1} \frac{1}{1 - (1 - \mathbf{A} \mathbf{U} \mathbf{V} \mathbf{A}^{-1})} \mathbf{A}$$

(58)
The second Neumann series converges by

\[ \|1 - \mathbf{A} \mathbf{U} \mathbf{V} \mathbf{A}^{-1}\| = \|\mathbf{A} (1 - \mathbf{U} \mathbf{V}) \mathbf{A}^{-1}\| \leq \|\mathbf{A}\| \|1 - \mathbf{U} \mathbf{V}\| \|\mathbf{A}^{-1}\| \leq 256 \cdot 2^{-16} \cdot 1 = 2^{-8} < 1 \]

The estimates (39e), (39f) follow from

\[ \|\mathbf{U}^{-1} \mathbf{A}^{-1}\|_{\mathbb{R} \oplus \mathbf{V}} \leq (1 - 2^{-8})^{-1} \quad \|\mathbf{U}^{-1}\|_{\mathbb{R} \oplus \mathbf{V}} \leq (1 - 2^{-8})^{-1} 2^8 \]

The file INV_0_0_250_750.dat was generated on an HPC cluster. It contains the result of applying (56) to all 654375 unit vectors \( e \in \text{image} \). For example, it contains a line for the unit vector with \( (e_4)_{1,7} = 1 \),

\[
\begin{align*}
3_1_1_7 & \quad 580 \cdot 2^{-32} \quad \text{TRUE} \quad 1156600 \cdot 2^{-13} \quad \text{TRUE} \\
\end{align*}
\]

This line asserts the existence of a vector \( f \in \mathbb{R} \oplus (\mathbf{V}_{\text{Gauged}} \cap \text{image} \mathbf{s}) \) with

\[ \|e - \mathbf{U} f\|_{\mathbf{V}} / \|e\|_{\mathbf{V}} \leq 580 \cdot 2^{-32} \quad \|f\|_{\mathbb{R} \oplus \mathbf{V}} / \|e\|_{\mathbf{V}} \leq 1156600 \cdot 2^{-13} \quad (59) \]

The first TRUE indicates that \( 580 \cdot 2^{-32} \leq 2^{-16} \), the second indicates that \( 1156600 \cdot 2^{-13} \leq \|\mathbf{A} e\|_{\mathbf{V}} / \|e\|_{\mathbf{V}} \), where \( \|\mathbf{A} e\|_{\mathbf{V}} / \|e\|_{\mathbf{V}} = 256 \) for this particular \( e \). Partially define \( \mathbf{V} \) by \( \mathbf{V} e = f \). Analogous statements for all unit vectors \( e \) define \( \mathbf{V} \) completely, and yield (57).

\[
\begin{align*}
\end{align*}
\]

Set

\[ \mathcal{R} = 2^{-277} \leq 10^{-83} \quad (60a) \]

\[ \begin{align*}
\end{align*} \]

The resulting fixed point \( (\mu, \omega) \) satisfies

\[ |\mu - (\mu_{\text{refA}} + \mu_{\text{refB}})| \leq 2^{-277} \quad \|\omega - (\omega_{\text{refA}} + \omega_{\text{refB}})\|_{\mathbf{V}} \leq 2^{-277} \quad (60b) \]

We proceed analogously with the \( # \) system.

(48a): Use (47) with \( \mathbf{v} = \omega_{\text{refA}} \). Use \texttt{choptuik DedicatedGamma2}.

(48b): Use the triangle inequality, \texttt{choptuik LoadAplusB} and (60).

(48c): Note that (52d) holds, and to check (52b) use the command

\texttt{choptuik SHARP_EXTERIOR_ESTIMATE offm_offn_numm_numn}

or see \texttt{SHARP_EXTERIOR_ESTIMATE_0_0_1600_4800.dat}

\[
\begin{align*}
\end{align*} \]
For (48d) and (48e), use

```
choptuik SHARP_INV offm_offn_numm_numn
```
or see SHARP_INV_0_0_250_750.dat

There exists a linear map \( \mathbb{V}^2 : \mathcal{A}^2 \to \mathcal{A}^2 \) with \( \mathbb{V}^2 = s \mathcal{A}^2 s + (1 - s) \) and

\[ \| 1 - \mathbb{V}^2 \mathcal{A}^2 \|_{\mathcal{A}^2 \to \mathcal{A}^2} \leq 2^{-16} \quad \| \mathcal{A}^2 (2 \mathcal{A}^2)^{-1} \|_{\mathcal{A}^2 \to \mathcal{A}^2} \leq 1 \]

Now. We are done with all the \( \blacklozenge \) in Section 4, and we now have a solution to 2DprobSeries.

To see that we also have a solution to 2Dprob, i.e. a solution to the Einstein equations with massless scalar field, we still have to check (b) and (d) in 2Dpre with \( \xi_* = \frac{1}{2} (\kappa_2 + 1/\kappa_2) = 41/40 \). Let \( \mathcal{Z} \) be the cylinder (12). Then

\[
\sup_{(\tau, \xi) \in \mathcal{Z}} | \text{ToSeries}(v) | \leq \| v \|_{\mathcal{A}^2}
\]

follows from \( |z| \leq \| z \|_{\mathbb{C}} \) and \( |e^{\pm i \theta}| \leq \kappa_2 \) for all \( \theta \in \mathbb{C} \) with \( \cos \theta \in (-\xi_*, \xi_*) \). Since \( \| \mu_{\text{refB}} \oplus \omega_{\text{refB}} + \mu_{\text{corr}} \oplus \omega_{\text{corr}} \|_{\mathbb{R} \oplus \mathbb{V}} \leq 2^{-24} \blacklozenge \), we have

\[
| \mu - \mu_{\text{refA}} | + \sum_{i=1}^4 \sup_{(\tau, \xi) \in \mathcal{Z}} | \text{ToSeries}(\omega_i - \omega_{\text{RefA},i}) | \leq 2^{-24} \blacklozenge.
\]

Now, (b) and (d) follow immediately by analyzing the data in RefA.dat.

For (2) and (3), note that \( | \mu - (\mu_{\text{refA}} + \mu_{\text{refB}}) | \leq 10^{-83} \blacklozenge \) and

\[
\left| K - \left( 2\pi (\mu_{\text{refA}} + \mu_{\text{refB}}) - \int_0^{2\pi} d\tau (\omega_{\text{RefA},3} + \omega_{\text{RefB},3})(\tau,0) \right) \right| \leq 2\pi \| \mu_{\text{corr}} \oplus \omega_{\text{corr}} \|_{\mathbb{R} \oplus \mathbb{V}} \leq 10^{-82} \blacklozenge
\]

See (15b). Now, the data in RefAplusB.dat, or more conveniently the command choptuik LoadAplusB, yield inequalities (2) and (3).

6 Data structures

To enable the interested reader to translate between this paper and the accompanying C source code in the directory sourcecode (arXiv ancillary files), we introduce the basic data structures that we use, and explain what data they represent.

The type Sector contains four non-negative integers,
typedef struct
{
    unsigned long off_m;
    unsigned long off_n;
    unsigned long num_m;
    unsigned long num_n;
} Sector;

and represents a rectangular region of Fourier-Chebyshev indices \((m, n)\):

\[
\begin{align*}
    \text{off}_m \leq m & < \text{off}_m + \text{num}_m \\
    \text{off}_n \leq n & < \text{off}_n + \text{num}_n
\end{align*}
\]

The type GI contains two arbitrary precision integers (\(\text{mpz}_t\) from \texttt{gmp.h}):

typedef struct
{
    \text{mpz}_t \text{Re};
    \text{mpz}_t \text{Im};
} GI;

and represents the Gaussian integer \(\text{Re} + i \text{Im} \in \mathbb{Z} + i\mathbb{Z}\). The type

typedef struct
{
    long TwoExp;
    Sector sec;
    GI** data;
} Field;

represents the field \(v = (v_{mn}) \in \mathcal{V}\) given by

\[
v_{\text{sec.off}_m+u, \text{sec.off}_n+v} = 2^{\text{TwoExp}} \text{data}[u][v]
\]

for all \(u\) and \(v\) with: \(0 \leq u < \text{sec.num}_m\) and \(0 \leq v < \text{sec.num}_n\)

and \(v_{mn} = 0\) for all \(m, n \geq 0\) not in \(\text{sec}\). The offsets \(\text{off}_m, \text{off}_n\) allow us to efficiently store and calculate with fields \(v\) that are 'strongly localized' in frequency space. For example, for tasks (2a), (2b), (3) in Section 1.3, we often use fields with \(\text{off}_m \gg \text{num}_m\) or \(\text{off}_n \gg \text{num}_n\). The type

typedef struct
{
    long TwoExp;
    \text{mpz}_t \text{coeff};
} DyadicQ;
represents the dyadic rational number $\text{coeff} \cdot 2^{\text{TwoExp}}$. The type

```c
typedef struct
{
    unsigned long num_comp;
    Field* comp;
} MultiField;
```

represents the multifield $(\text{comp}[0], \ldots, \text{comp}[\text{num}\_\text{comp}-1]) \in \mathcal{V}^{\text{num}\_\text{comp}}$, and

```c
typedef struct
{
    DyadicQ mu;
    MultiField mf;
} mu\_MultiField;
```

represents $(\mu, \text{mf}) \in \mathbb{R} \oplus \mathcal{V}^{\text{nf} \cdot \text{num}\_\text{comp}}$. One can now also read the text files RefA.dat and RefAplusB.dat, each contains a mu\_MultiField.
