A unitary invariant of semi-bounded operator in reconstruction of manifolds

M.I. Belishev *

Abstract

With a densely defined symmetric semi-bounded operator of nonzero defect indexes $L_0$ in a separable Hilbert space $H$ we associate a topological space $\Omega_{L_0}$ (wave spectrum) constructed from the reachable sets of a dynamical system governed by the equation $u_{tt} + (L_0)^*u = 0$. Wave spectra of unitary equivalent operators are homeomorphic.

In inverse problems, one needs to recover a Riemannian manifold $\Omega$ via dynamical or spectral boundary data. We show that for a generic class of manifolds, $\Omega$ is isometric to the wave spectrum $\Omega_{L_0}$ of the minimal Laplacian $L_0 = -\Delta|_{C^\infty_0(\Omega\setminus\partial\Omega)}$ acting in $\mathcal{H} = L_2(\Omega)$, whereas $L_0$ is determined by the inverse data up to unitary equivalence. Hence, the manifold can be recovered (up to isometry) by the scheme ‘data $\Rightarrow L_0 \Rightarrow \Omega_{L_0} \text{isom} \Rightarrow \Omega$’.

The wave spectrum is relevant to a wide class of dynamical systems, which describe the finite speed wave propagation processes. The paper elucidates the operator background of the boundary control method (Belishev’1986), which is an approach to inverse problems based on their relations to control theory.

0 Introduction

0.1 Motivation

The paper introduces the notion of a wave spectrum of a symmetric semi-bounded operator in a Hilbert space. The impact comes from inverse prob-
lems of mathematical physics; the following is one of the motivating questions.

Let $\Omega$ be a smooth compact Riemannian manifold with the boundary $\Gamma$, $-\Delta$ the (scalar) Laplace operator, $L_0 = -\Delta|_{C_0^\infty(\Omega \setminus \Gamma)}$ the minimal Laplacian in $\mathcal{H} = L_2(\Omega)$. Assume that we are given with a unitary copy $\tilde{L}_0 = UL_0U^*$ in a space $\tilde{\mathcal{H}} = U\mathcal{H}$ (but $\Omega, \mathcal{H}$ and $U$ are unknown!). To what extent does $\tilde{L}_0$ determine the manifold $\Omega$?

So, we have no points, boundaries, tensors, etc, whereas the only thing given is an operator $\tilde{L}_0$ in a Hilbert space $\tilde{\mathcal{H}}$. Provided the operator is unitarily equivalent to $L_0$, is it possible to ‘extract’ $\Omega$ from $\tilde{L}_0$? Such a question is an invariant version of various setups of dynamical and spectral inverse problems on manifolds [2], [4].

0.2 Content

Substantially, the answer is affirmative: for a generic class of manifolds, any unitary copy of the minimal Laplacian determines $\Omega$ up to isometry (Theorem 1). A wave spectrum is a construction that realizes the determination $\tilde{L}_0 \Rightarrow \Omega$ and thus solves inverse problems. In more detail,

- With a closed densely defined symmetric semi-bounded operator $L_0$ of nonzero defect indexes in a separable Hilbert space $\mathcal{H}$ we associate a topological space $\Omega_{L_0}$ (its wave spectrum). The space consists of the atoms of a lattice with inflation determined by $L_0$. The lattice is composed of reachable sets of an abstract dynamical system with boundary control governed by the evolutionary equation $u_{tt} + L_0^*u = 0$. The wave spectrum is endowed with a relevant topology.

Since the definition of $\Omega_{L_0}$ is of invariant character, the spectra $\Omega_{L_0}$ and $\Omega_{\tilde{L}_0}$ of unitarily equivalent operators $L_0$ and $\tilde{L}_0$ turn out to be homeomorphic. So, a wave spectrum is a (hopefully, new) unitary invariant of a symmetric semi-bounded operator.

- A wide generic class of the so-called simple manifolds is introduced\(^1\). The central Theorem 1 establishes that for a simple $\Omega$, the wave spectrum of its minimal Laplacian $L_0$ is metrizable and isometric to $\Omega$. Hence, any unitary copy $\tilde{L}_0$ of $L_0$ determines the simple $\Omega$ up to isometry by the scheme

\(^1\)Roughly speaking, a simplicity means that the symmetry group of $\Omega$ is trivial.
\( \tilde{L}_0 \Rightarrow \Omega_{L_0} \overset{\text{isom}}{=} \Omega_{L_0} \overset{\text{isom}}{=} \Omega \). In applications, it is the procedure, which recovers manifolds by the boundary control method [2],[4]: concrete inverse data determine the relevant \( \tilde{L}_0 \), what enables one to realize the scheme.

- We discuss one more option: elements of the space \( \mathcal{H} \) can be realized as ‘functions’ on \( \Omega_{L_0} \). Hopefully, this observation can be driven at a functional model of a class of \( L_0 \)s and/or Spaces of Boundary Values. Presumably, this model will be local, i.e., satisfying supp \((L_0^{\text{mod}})^*y \subseteq \text{supp } y\).

### 0.3 Comments

- The concept of wave spectrum summarizes rich ‘experimental material’ accumulated in inverse problems of mathematical physics in the framework of the BC-method, and elucidates its operator background. For the first time, \( \Omega_{L_0} \) has appeared in [1] in connection with the M.Kac problem; its later version (called a wave model) is presented in [4] (sec 2.3.4). Owing to its invariant nature, \( \Omega_{L_0} \) promises to be useful for further applications to unsolved inverse problems of elasticity theory, electrodynamics, graphs, etc.

  Our paper is of pronounced interdisciplinary character. ‘Wave’ terminology, which we use, is motivated by close relations to applications.

- The path from \( L_0 \) to \( \Omega_{L_0} \) passes through an intermediate object, which is a sublattice of the lattice \( \mathfrak{L}(\mathcal{H}) \) of subspaces of the space \( \mathcal{H} \). Section 1 is an excursus to the lattice theory, in course of which we introduce lattices with inflation. The wave spectrum appears as a set of atoms of the relevant lattice with inflation determined by \( L_0 \).

- We give attention to connections of our approach with C*-algebras. As is shown, if \( \Omega \) is a compact manifold then \( \Omega_{L_0} \) is identical to the Gelfand spectrum of the algebra of continuous functions \( C(\Omega) \). By the recent trend in the BC-method, to recover unknown manifolds via boundary inverse data is to find spectra of relevant algebras determined by the data [5]. We hope for utility and further promotion of this trend.

**Acknowledgements** I would like to thank A.B.Alexandrov for kind consultations, and V.I.Vasyunin and N.Wada for useful discussions on the subject of the paper.

---

2In the BC-method, such an option is interpreted as visualization of waves [4].
1 Lattices with inflation

Reducing the volume of the paper, we do not prove Propositions. The proofs are quite elementary and typical technique is demonstrated in Appendix.

1.1 Basic objects

1. Lattice. Let $\mathcal{L}$ be a lattice, i.e. a partially ordered set (poset) with the order $\leq$ and operations $a \land b = \inf\{a, b\}$, $a \lor b = \sup\{a, b\}$. Also, we assume that $\mathcal{L}$ is endowed with the least element $0$ satisfying $0 < a$ for $a \neq 0$.

The order topology on $\mathcal{L}$ is introduced through the order convergence: $x_j \to x$ if there are the nets $\{a_j\}_{j \in J} \uparrow$ and $\{b_j\}_{j \in J} \downarrow$ ($J$ is a directed set) such that $a_j \leq x_j \leq b_j$ and $\sup\{a_j\} = x = \inf\{b_j\}$ holds (we write $a_j \uparrow x$ and $b_j \downarrow x$). For an $A \subset \mathcal{L}$, the inclusion $x \in A$ occurs if and only if there are $a_j, b_j \in A$ such that $a_j \uparrow x$ and/or $b_j \downarrow x$.

Example 1. The lattice $\mathcal{L} = 2^\Omega$ of subsets of a set $\Omega$ with the order $\subseteq$, operations $\land = \cap$, $\lor = \cup$, and $0 = \emptyset$.

Example 2. The (sub)lattice $\mathcal{O} \subset 2^\Omega$ of open sets of a topological space $\Omega$. The convergence $\omega_j \uparrow \omega$ means $\omega = \sup\{\omega_j\} = \cup \omega_j$. The convergence $\omega_j \downarrow \omega$ means $\omega = \inf\{\omega_j\} = \text{int} \cap \omega_j$, where $\text{int} A$ is the set of interior points of $A \subset \Omega$.

2. Inflation. For a lattice $\mathcal{L}$, the set $\mathcal{F}_\mathcal{L} := \mathcal{F} ([0, \infty); \mathcal{L})$ of $\mathcal{L}$-valued functions is also a topologized lattice with respect to the point-wise order, operations, and topology.

Definition 1. A map $I : \mathcal{L} \to \mathcal{F}_\mathcal{L}$ is said to be an inflation if for all $a, b \in \mathcal{L}$ and $s, t \in [0, \infty)$ one has

(i) $(Ia)(0) = a$ and $I0_{\mathcal{L}} = 0_{\mathcal{F}_\mathcal{L}}$,

(ii) $a \leq b$ and $s \leq t$ imply $(Ia)(s) \leq (Ib)(t)$.

Inflation is injective: $I^{-1}f = f(0)$ on $I\mathcal{L}$.

Example 3. $\Omega$ is a metric space with the distance $d$. For a subset $A \subset \Omega$, by $A^t := \{x \in \Omega \mid d(x, A) < t\}$ ($t > 0$) we denote its metric neighborhood, ant put $A^0 := A$, $\emptyset^t = \emptyset$. The map $M : 2^\Omega \to \mathcal{F}_{2^\Omega}$, $(MA)(t) := A^t$, $t \geq 0$ is a metric inflation. The image $M2^\Omega$ is a semilattice: $Ma \lor Mb = M(a \lor b) \in M2^\Omega$. The image of open sets is a (sub)semilattice $M\mathcal{O} \subset \mathcal{F}_{\mathcal{O}} \subset \mathcal{F}_{2^\Omega}$.

---

3 Everywhere ( ) denotes a topological closure. In some places, to avoid the confusion, we specify the space.
3. Atoms. Basic construction. Let $P$ be a poset with the least element $0$. An $\alpha \in P$ is called an atom if $0 < a \leq \alpha$ implies $a = \alpha$. By $\text{At } P$ we denote the set of atoms.

Example 4. Each atom of $2^\Omega$ is a single point set: $\text{At } 2^\Omega = \{ \{ x \} \mid x \in \Omega \}$.

Example 5. If the open sets of a topological space $\Omega$ are infinitely divisible then $\text{At } \Omega = \emptyset$.

Inflation preserves atoms: $I \text{At } L \subseteq \text{At } I L$. For any lattice with inflation, the set $\Omega I L := \text{At } I L \subset F L$ (the closure in topology of $FL$) is well defined. This set is a key object of the paper. Namely, the following effect will be exploited: there are lattices and inflations such that $\text{At } L = \emptyset$ but $\text{At } I L \neq \emptyset$. Inflation can create atoms!

There is a natural topology on $\Omega I L \subset F L$. For atoms $\alpha, \beta \in \Omega I L$, we say that $\alpha$ influences on $\beta$ at the moment $t$ if $\alpha(t) \wedge \beta(\varepsilon) \neq 0_L$ for any positive $\varepsilon$. Define $t_{\alpha\beta} := \inf \{ t \geq 0 \mid \alpha(t) \wedge \beta(\varepsilon) \neq 0_L \forall \varepsilon > 0 \}$. If $\alpha(t) \wedge \beta(\varepsilon) = 0_L$ for all positive $t$ and $\varepsilon$, we put $t_{\alpha\beta} = \infty$.

A function $\tau I L : \Omega I L \times \Omega I L \to [0, \infty) \cup \{ \infty \}$, $\tau I L (\alpha, \beta) := \max \{ t_{\alpha\beta}, t_{\beta\alpha} \}$ is called an interaction time.

Define the ‘balls’ $B^r[\alpha] := \{ \beta \in \Omega I L \mid \tau I L (\alpha, \beta) < r \} (r > 0)$, $B^0[\alpha] := \alpha$.

Definition 2. By $(\Omega I L, \tau I L)$ we denote the topological space that is the set $\Omega I L$ endowed with the minimal topology, which contains all balls.

Surely, at this level of generality, to expect for rich properties of this space is hardly reasonable. However, in ‘good’ cases the function $\tau I L$ turns out to be a metric.

Proposition 1 Let $(\Omega, d)$ be a complete metric space, $\mathcal{L} = 2^\Omega$, $I = M$ (see Example 3). The correspondence $\Omega \ni x \leftrightarrow M \{ x \} \in F 2^\Omega$ is a bijection between the sets $\Omega$ and $\Omega M 2^\Omega = \text{At } M 2^\Omega = \text{At } M 2^\Omega = \text{At } M 2^\Omega = \{ M \{ x \} \mid x \in \Omega \}$. The equality $\tau M 2^\Omega (M \{ x \}, M \{ y \}) = d(x, y)$ holds. Function $\tau M 2^\Omega$ is a metric on atoms, whereas $(\Omega M 2^\Omega, \tau M 2^\Omega)$ is a metric space isometric to $(\Omega, d)$. The isometry is realized by the bijection $M \{ x \} \leftrightarrow x$.

There are another topologies on atoms, which are also inspired by the metric topology. The first one is introduced via closure operation: for a set

\[ i.e., \text{for any } \emptyset \neq A \in \mathcal{O} \text{ there is } \emptyset \neq B \in \mathcal{O} \text{ such that } B \subset A \text{ and } A \setminus B \neq \emptyset. \]

\[ \text{But the case } \Omega I L = \emptyset \text{ is not excluded.} \]
$W \subset \Omega_{IL}$, we put

$$\overline{W} := \left\{ \alpha \in \Omega_{IL} \middle| \bigvee_{\beta \in W} \beta \geq \alpha \right\}.$$

It is easy to check that the map $W \mapsto \overline{W}$ satisfies all Kuratovsky's axioms and, hence, determines a unique topology $\rho_{IL}$ in $\Omega_{IL}$. Note a certain resemblance (duality) of such a topology to Jacobson's topology on the set $\mathcal{I}$ of primitive ideals of a C*-algebra $\mathcal{A}$. Namely, for a $W \subset \mathcal{I}$, one defines its closure by

$$\overline{W} := \left\{ i \in \mathcal{I} \middle| \bigcap_{b \in W} b \subseteq i \right\}$$

(see, e.g., [15]).

One more topology is the following. We define the ‘balls’ by

$$B^r[\alpha] := \left\{ \beta \in \Omega_{IL} \middle| \exists t_0 = t_0(\alpha, \beta, r) > 0 \text{ s.t. } 0 \neq \beta(t_0) \leq \alpha(r) \right\} \quad (r > 0).$$

As one can verify, the system $\{B^r[\alpha]\}_{\alpha \in \Omega_{IL}, r > 0}$ is a base of topology. Hence, it determines a unique topology that we denote by $\sigma_{IL}$.

If $\mathcal{L} = 2^{\mathbb{R}^n}$ and $I$ is the (Euclidean) metric inflation, the topologies $\tau_{IL}, \rho_{IL},$ and $\sigma_{IL}$ coincide with the standard Euclidean metric topology in $\mathbb{R}^n$.

4. **Isomorphic lattices.** Let $\mathcal{L}$ and $\mathcal{L}'$ be two lattices with inflations $I$ and $I'$ respectively. We say them to be isomorphic through a bijection $i : \mathcal{L} \rightarrow \mathcal{L}'$ if $i$ preserves the order, lattice operations, and $i(IA) = I'i(A)$ holds for all $A \in \mathcal{L}$.

The bijection $i$ is extended to bijection on functions $i : \mathcal{F}_\mathcal{L} \rightarrow \mathcal{F}_{\mathcal{L}'}$ by $(if)(t) := i(f(t)), \ t \geq 0$. The following fact is quite obvious.

**Proposition 2** If the lattices with inflation $\mathcal{L}$ and $\mathcal{L}'$ are isomorphic then the spaces $(\Omega_{IL}, \tau_{IL})$ and $(\Omega_{I'L'}, \tau_{I'L'})$ are homeomorphic. The homeomorphism is realized by the bijection $i$ on atoms.

1.2 **Lattices in metric space**

5. **Lattice $\mathcal{O}$.** Return to Example 3 and assume in addition that $A1. \Omega$ is a complete metric space
A2. All the balls \( \{x\}^t \) are compact and \( \{x\}^t \setminus \{x\}^s \neq \emptyset \) as \( s < t \).

By A2, open sets are infinitely divisible. Therefore, we have \( \text{At} \mathcal{O} = \emptyset \).

Fix an \( x \in \Omega \) and define the functions \( x_*, x^* \in \mathcal{F}_\mathcal{O}: x_*(t) := \{x\}^t \) as \( t > 0 \), \( x_*(0) := 0_\mathcal{O} \), and \( x^*(t) := \text{int}\{x\}^t \) as \( t \geq 0 \). Evidently, we have \( x_* \leq x^* \) in \( \mathcal{F}_\mathcal{O} \). The upper function satisfies \( x^* = \lim_{\varepsilon \to 0} M(\{x\}^t) \in \overline{\mathcal{M}\mathcal{O}} \), \( x^*(0) = 0_\mathcal{O} \). The ‘clearance’ between the functions is small: \( x_*(t) = x^*(t), \ t \geq 0 \).

Since \( x^* \in \overline{\mathcal{M}\mathcal{O}} \), the segment \( [x_*, x^*] := \{ f \in \mathcal{F}_\mathcal{O} | x_* \leq f \leq x^* \} \) intersects with \( \overline{\mathcal{M}\mathcal{O}} \). The poset \( [x_*, x^*] \cap \overline{\mathcal{M}\mathcal{O}} \) is a closed subset in \( \mathcal{F}_\mathcal{O} \) bounded from below. Hence, it contains minimal elements, which can be easily recognized as the atoms of \( \overline{\mathcal{M}\mathcal{O}} \). So, \( \Omega_{\mathcal{M}\mathcal{O}} := \text{At}\overline{\mathcal{M}\mathcal{O}} \neq \emptyset \).

Example 6. For \( \Omega \subseteq \mathbb{R}^n \) one has \( x_* = x^* \). Therefore, each segment \( [x_*, x^*] \) contains one (and only one) atom \( \{x\}^t \), \( t \geq 0 \). We don’t know whether the same is correct for a Riemannian manifold \( \Omega \).

For an atom \( \alpha \in \text{At}\overline{\mathcal{M}\mathcal{O}} \), define a kernel \( \dot{\alpha} := \cap_{t>0} \alpha(t) \subset \Omega \).

Proposition 3 For each \( \alpha \), its kernel \( \dot{\alpha} \) consists of a single point \( x_\alpha \in \Omega \). Each atom \( \alpha \) belongs to the segment \( [(x_\alpha)_*, (x_\alpha)^*] \). If \( \dot{\alpha} = \dot{\beta} \) then \( \alpha(t) = \beta(t), \ t \geq 0 \) holds.

These facts follow from a general lemma stated and proved in Appendix.

With each \( x \in \Omega \) one associates the class of atoms \( \langle \alpha \rangle_x := [x_*, x^*] \cap \text{At}\overline{\mathcal{M}\mathcal{O}} \). For \( \alpha, \beta \in \langle \alpha \rangle_x \) one has \( \dot{\alpha}(t) = \dot{\beta}(t) (= \{x\}^t), \ t \geq 0 \). Hence, \( \alpha \) and \( \beta \) interact at any \( t > 0 \). As a result, we have \( \tau_{\mathcal{M}\mathcal{O}}(\alpha, \beta) = 0 \).

The relation \( \{\alpha \sim \beta\} \leftrightarrow \{\tau_{\mathcal{M}\mathcal{O}}(\alpha, \beta) = 0\} \) is an equivalence on \( \Omega_{\mathcal{M}\mathcal{O}} \). The factor-set \( \Omega'_{\mathcal{M}\mathcal{O}} := \Omega_{\mathcal{M}\mathcal{O}}/\sim \) is bijective to \( \Omega \) through the map \( \langle \alpha \rangle \mapsto \dot{\alpha} \).

The function \( \tau'_{\mathcal{M}\mathcal{O}}(\langle \alpha \rangle_x, \langle \beta \rangle_y) := \tau_{\mathcal{M}\mathcal{O}}(\alpha, \beta) \) is a metric on \( \Omega'_{\mathcal{M}\mathcal{O}} \). The equality \( \tau_{\mathcal{M}\mathcal{O}}(\langle \alpha \rangle_x, \langle \alpha \rangle_y) = d(x, y) \) is valid for all \( x, y \in \Omega \) and we conclude the following.

Proposition 4 The metric space \( (\Omega'_{\mathcal{M}\mathcal{O}}, \tau'_{\mathcal{M}\mathcal{O}}) \) is isometric to \( (\Omega, d) \). The isometry is realized by the bijection \( \langle \alpha \rangle_x \leftrightarrow x \).

6. Lattice \( \mathcal{O}^{\text{reg}} \). For a set \( A \subseteq \Omega \), denote by \( \partial A := \overline{A \cap \Omega \setminus A} \) its boundary. Note that \( \partial(A \cap B) \subseteq \partial A \cup \partial B \) and \( \partial(A \cup B) \subseteq \partial A \cup \partial B \). It is convenient to put \( \partial \emptyset = \partial \emptyset = \emptyset \).

Recall that we deal with complete and locally compact metric spaces (see A1.2). In addition, assume that \( \Omega \) is endowed with a Borel measure \( \mu \) such that
A3. For any $A \subset \Omega$ and $t > 0$, the relation $\mu(\partial A^t) = 0$ holds.

Example 7. $\Omega$ is a smooth Riemannian manifold with the canonical measure (volume). In particular, $\Omega \subseteq \mathbb{R}^n$ with the Lebesgue measure $\mu$. 

Definition 3. An open set $A \subset \Omega$ is called regular if $\mu(\partial A) = 0$. The system of regular sets is denoted by $\mathcal{O}^{\text{reg}}$.

As is evident, $\mathcal{O}^{\text{reg}}$ is a sublattice in $\mathcal{O}$. It is a base of $\mathcal{O}$: each open set is a sum of regular sets (balls). By A3, $\mathcal{O}^{\text{reg}}$ is invariant w.r.t. the metric inflation: $(M\mathcal{O}^{\text{reg}})(t) \subset \mathcal{O}^{\text{reg}}$, $t \geq 0$. In other words, we have $M\mathcal{O}^{\text{reg}} \subset \mathcal{F}\mathcal{O}^{\text{reg}}$.

Fix an $x \in \Omega$. Note that $x^*, x^* \in \mathcal{F}\mathcal{O}^{\text{reg}}$ and $x^* \in M\mathcal{O}^{\text{reg}}$. Using the arguments quite analogous to ones, which have led to Proposition 4, and factorizing the set of atoms w.r.t. the same equivalence $\sim$, one can arrive at the following result.

Proposition 5 The metric space $(\Omega', M\mathcal{O}^{\text{reg}}, \tau'_{M\mathcal{O}^{\text{reg}}})$ is isometric to $(\Omega, d)$. The isometry is realized by the bijection $\langle \alpha \rangle \leftrightarrow x$.

The operation $A \mapsto A^* := \text{int}(\Omega \setminus A)$ is well defined on $\mathcal{O}^{\text{reg}}$ and called a pseudo-complement [7]. The relations $A \cap A^* = \emptyset$ and $A \subseteq (A^*)^*$ are valid.

7. Lattice $\mathfrak{R}$. Introduce an equivalence on $\mathcal{O}^{\text{reg}}$: we put $A \sim B$ if $A = B$. Define $\mathfrak{R} := \mathcal{O}^{\text{reg}}/\sim$. By $[A]$ we denote the equivalence class of $A$.

Endow $\mathfrak{R}$ with the order and operations:

$[A] \leq [B]$ if $A \subseteq B$
$[A] \land [B] := [A \cap B]$, $[A] \lor [B] := [A \cup B]$
$[A]^\perp := [A^*] = ([\text{int}(\Omega \setminus A)]).

The least and greatest elements are $0 := [\emptyset]$ and $1 := [\Omega]$.

One can easily check the well-posedness of these definitions and prove the following relations:

$[A] \land [A]^\perp = 0$, $[A] \lor [A]^\perp = 1$
$([A] \land [B])^\perp = [A]^\perp \lor [B]^\perp$, $([A] \lor [B])^\perp = [A]^\perp \land [B]^\perp$.

Hence $\mathfrak{R}$ is a lattice with the complement $[.]^\perp$ [7].

For $f \in \mathcal{F}\mathcal{O}^{\text{reg}}$, define $[f] \in \mathcal{F}\mathfrak{R}$, $[f](t) := [f(t)]$, $t \geq 0$.

Introduce the metric inflation on $\mathfrak{R}$ by $M : \mathfrak{R} \to \mathcal{F}\mathfrak{R}$, $(M[A])(t) := ([MA](t)] = [A^t]$, $t \geq 0$.

The relation $\text{AtM}\mathfrak{R} = \{[\alpha] | \alpha \in \text{AtM}\mathcal{O}^{\text{reg}}\}$ holds. The map $A \mapsto [A]$ identifies the atoms belonging to the same class: if $\alpha, \beta \in \langle \alpha \rangle_x$ then $\alpha(t) = \beta(t)$.

\[\text{Our definition is similar to (but differs from) the definition of regularity in [7], p 216.}\]
\( \beta(t), \ t \geq 0 \) that implies \([\alpha] = [\beta]\. By this, the set \( \Omega_{MR} = \text{At}M\mathcal{R} \) is bijective to \( \Omega \), whereas the ‘interaction time’ \( \tau_{MR} \) turns out to be a metric.

**Proposition 6** The metric space \( (\Omega_{MR}, \tau_{MR}) \) is isometric to \( (\Omega, d) \). The isometry is realized by the bijection \([\alpha] \leftrightarrow x_\alpha\.\)

8. **Lattice \( \mathcal{R}^H \).** Introduce a Hilbert space \( \mathcal{H} := L_{2,\mu}(\Omega) \).

For a measurable set \( A \subset \Omega \), define the subspace \( \mathcal{H}A := \{\chi_A y | y \in \mathcal{H}\} \), where \( \chi_A \) is the indicator of \( A \). Such subspaces are called geometric. If \( A \in \mathcal{O}^{\text{reg}} \) then \( \mu(\overline{A} \setminus A) = \mu(\partial A) = 0 \) that leads to \( H\overline{A} = HA \).

**Definition 4.** If \( A \in \mathcal{O}^{\text{reg}} \), we say the subspace \( \mathcal{H}A \) to be regular. The system of regular subspaces is denoted by \( \mathcal{R}^H \).

Let \( L(\mathcal{H}) \) be the lattice of subspaces of the space \( \mathcal{H} \) (see item 10 below). The system \( \mathcal{R}^H \subset L(\mathcal{H}) \) is a sublattice.

Introduce a map \( i : \mathcal{R} \to \mathcal{R}^H \), \( i[A] := \mathcal{H}A \). As is easy to check, it preserves the operations and complement.\(^7\)

Extend \( i \) to functions: for an \( f \in \mathcal{F}_\mathcal{R} \) we put \( if \in \mathcal{F}_\mathcal{R}^H \subset \mathcal{F}_{L(\mathcal{H})} \), \( (if)(t) := i(f(t)), \ t \geq 0 \). Also, define a metric inflation on \( \mathcal{R}^H \) by \( iM : \mathcal{R}^H \to \mathcal{F}_{L(\mathcal{H})} \), \( (iM\mathcal{H}A)(t) := H((MA)(t)) = i[A^t] = HA^t, \ t \geq 0 \).

Thus, \( i \) is an isomorphism of lattices with inflation. Propositions 3 and 6 lead to the following result.

**Proposition 7** The metric space \( (\Omega_{iM\mathcal{R}^H}, \tau_{iM\mathcal{R}^H}) \) is isometric to \( (\Omega, d) \). The isometry is realized by the bijection \( i[\alpha] \leftrightarrow x_\alpha \).

The meaning of the passage \( \mathcal{O}^{\text{reg}} \to \mathcal{R}^H \) is that it ‘codes’ regular sets in Hilbert terms. Later in inverse problems, we will determine the Hilbert lattices from inverse data, and then ‘decode’ them, i.e., extract information about geometry of \( \Omega \).

9. **Dense sublattice.** We say a system of subsets \( \mathcal{N} \subset \mathcal{O}^{\text{reg}} \) to be dense in \( \mathcal{O}^{\text{reg}} \), if for any \( x \in \Omega \) and \( A \in \mathcal{O}^{\text{reg}} \), \( x \in A \) there is an \( N \in \mathcal{N} \) such that \( x \in N \subset A \). If, moreover, \( \mathcal{N} \) is a sublattice such that \( MN \subseteq N \) holds, we call it a dense \( M \)-invariant sublattice in \( \mathcal{O}^{\text{reg}} \).

Let \( \mathcal{R}_\mathcal{N} \subseteq \mathcal{R} \) be the image of \( \mathcal{N} \) through the map \( A \mapsto [A] \). The following fact can be derived as a consequence of density.

\(^7\)The latter means \( i([A]^\perp) = (HA)^\perp = H \cap HA = HA^* \).
Proposition 8  If $\mathcal{N}$ is a dense $M$-invariant sublattice, then the metric space $(\Omega_{\mathcal{M} \mathcal{R}_N}, \tau_{\mathcal{M} \mathcal{R}_N})$ is isometric to $(\Omega, d)$. The isometry is realized by the bijection $[\alpha] \leftrightarrow x_\alpha$.

Let $\mathcal{R}_N^H \subset \mathcal{R} \subset \mathcal{L}(\mathcal{H})$ be the image of $\mathcal{N}$ through the map $\mathcal{N} \ni N \mapsto \mathcal{H} N \in \mathcal{R}_N^H$. The image is an $iM$-invariant sublattice in $\mathcal{R}_N^H$. The next result is a straightforward consequence of the previous one.

Proposition 9  If $\mathcal{N} \subset \mathcal{O}_{\text{reg}}$ is a dense $M$-invariant sublattice then the metric space $(\Omega_{iM \mathcal{R}_N}, \tau_{iM \mathcal{R}_N})$ is isometric to $(\Omega, d)$. The isometry is realized by the bijection $i[\alpha] \leftrightarrow x_\alpha$.

Later, in applications, we will deal with concrete $\Omega$ and $\mathcal{N}$.

The relation $(\Omega, d) \overset{\text{isom}}{=} (\Omega_{iM \mathcal{R}_N}, \tau_{iM \mathcal{R}_N})$ is the final goal of our excursion to the lattice theory. It represents the original metric space as collection of atoms of relevant Hilbert lattice with inflation. This representation will play the key role in reconstruction of $\Omega$ via inverse data.

2 Wave spectrum

2.1 Inflation in $\mathcal{H}$

10. Basic objects. Let $\mathcal{H}$ be a separable Hilbert space, $\mathcal{L}(\mathcal{H})$ the lattice of its (closed) subspaces equipped with the order $\leq=\subseteq$, operations $A \land B = A \cap B$, $A \lor B = \{a+b \mid a \in A, b \in B\}$, the complement $A \mapsto A^\perp = \mathcal{H} \ominus A$, and extremal elements $0 = \{0\}$, $1 = \mathcal{H}$. A sublattice of $\mathcal{L}(\mathcal{H})$ is its subset closed w.r.t. the operations and complement. Each sublattice contains 0 and 1.

By $P_A$ we denote the (orthogonal) projection onto $A \in \mathcal{L}(\mathcal{H})$. Also, if $A$ is a non-closed lineal set, we put $P_A := P_A^\perp$.

Let $\mathcal{B}(\mathcal{H})$ be the algebra of bounded operators. For an $\mathcal{S} \subseteq \mathcal{B}(\mathcal{H})$, by Proj$\mathcal{S}$ we denote the set of projections belonging to $\mathcal{S}$.

For a lattice $\mathcal{L} \subseteq \mathcal{L}(\mathcal{H})$, with a slight abuse of notation, we put Proj$\mathcal{L} := \{P_A \mid A \in \mathcal{L}\}$. The map $\mathcal{L} \ni A \mapsto P_A \in \text{Proj}{\mathcal{L}}$ induces the lattice structure on Proj$\mathcal{L}$: $P_A \land P_B = P_{A \cap B}$, $P_A \lor P_B = P_{A \cup B}$, $(P_A)^\perp = P_{A^\perp}$. For $P, Q \in \text{Proj}{\mathcal{L}}$ the relation $P \leq Q$ means $\text{Ran} P \subseteq \text{Ran} Q$ and holds if and only if $(P x, x) \leq (Q x, x)$, $x \in \mathcal{H}$. The extremal elements of Proj$\mathcal{L}$ are the zero and unit operators $\mathbb{O}$ and $\mathbb{I}$. 
The same map relates the order topology on $\mathcal{L}(\mathcal{H})$ with the strong operator topology on $\mathfrak{B}(\mathcal{H})$: $A = \lim A_j$ in $\mathcal{L}(\mathcal{H})$ if and only if $P_A = s-\lim P_{A_j}$ in $\mathfrak{B}(\mathcal{H})$.

**Convention.** The metric inflation $iM$ in $\mathcal{H} = L_{2,\mu}(\Omega)$ is defined on a sublattice $\mathfrak{R}^H \subset \mathcal{L}(\mathcal{H})$ (item 8). In contrast to it, in what follows we deal with inflations defined on the whole $\mathcal{L}(\mathcal{H})$.

For an inflation $I : \mathcal{L}(\mathcal{H}) \to \mathcal{F}_{\mathcal{L}(\mathcal{H})}$, we denote $A^t := (IA)(t)$, $t \geq 0$. It is also convenient to regard inflation as an operation on projections: $I : \text{Proj}\mathfrak{B}(\mathcal{H}) \to \mathcal{F}_{\text{Proj}\mathfrak{B}(\mathcal{H})}$, $(IP)(t) = P^t := P_{(\text{Ran}P)(t)}$, $t \geq 0$.

A lattice $\mathfrak{L} \subset \mathcal{L}(\mathcal{H})$ is said to be $I$-invariant if $I \mathfrak{L} \subset \mathcal{F}_\mathfrak{L}$ holds, i.e. $A \in \mathfrak{L}$ implies $(IA)(t) \in \mathfrak{L}$, $t \geq 0$.

**Definition 5.** Let $f \subseteq \mathcal{L}(\mathcal{H})$ be a family of subspaces. Define $\mathfrak{L}[I,f] \subseteq \mathcal{L}(\mathcal{H})$ as the minimal $I$-invariant lattice, which contains $f$.

11. **Spectra.** Let $\mathcal{H}$ and $I$ be given, $\mathfrak{L}$ be an $I$-invariant lattice. Recall that the space of atoms with the ‘interaction’ topology was introduced in item 3.

**Definition 6.** The space $\Omega^\mathfrak{A}_\mathfrak{L} : = (\Omega_{I\mathfrak{L}}, \tau_{I\mathfrak{L}})$ is called an atomic spectrum of the lattice $\mathfrak{L}$.

There is a version of this notion. Each function $f \in \mathcal{T}\mathfrak{L} \subset \mathcal{F}_\mathfrak{L}$ is an increasing family of subspaces $\{f(t)\}_{t \geq 0} \subset \mathcal{L}(\mathcal{H})$, i.e. a nest [10]. The corresponding nest of projections $\{P^t_f\}_{t \geq 0}$, $P^t_f := P_{f(t)}$ determines a self-adjoint operator $E_f := \int_0^\infty t dP^t_f$. It acts in $\mathcal{H}$ and is called an eikonal. The set of eikonals is $\text{Eik}\mathfrak{L} := \{E_f \mid f \in \mathcal{T}\mathfrak{L}\}$.

**Definition 7.** A metric space $\Omega^\nest_\mathfrak{L} := \{E_\alpha \mid \alpha \in \Omega_{I\mathfrak{L}}\}$ with the distance $\|E_\alpha - E_\beta\|$ is called a nest spectrum of the lattice $\mathfrak{L}$.

**Caution!** We do not assume $E_\alpha$ to be a bounded operators, so that the ‘pathologic’ situation $\text{dist}(E_\alpha, E_\beta) \equiv \infty$ is not excluded. However, a ‘good’ case, when all the differences $E_\alpha - E_\beta$ are bounded operators, is realized in applications.

One more version is the following.

Let us say that we deal with a bounded case if the set of eikonals of the lattice is uniformly bounded: $\sup\{\|E\| \mid E \in \text{Eik}\mathfrak{L}\} < \infty$.

With a lattice $\mathfrak{L}$ one associates the von Neumann operator algebra $\mathfrak{N}_\mathfrak{L} \subseteq \mathfrak{B}(\mathcal{H})$ generated by the projections of $\mathfrak{L}$, i.e., the minimal von Neumann algebra satisfying $\text{Proj}\mathfrak{L} \subseteq \text{Proj}\mathfrak{N}_\mathfrak{L}$.

\[\text{i.e., a unital weekly closed self-adjoint subalgebra of } \mathfrak{B}(\mathcal{H}): \text{ see } [15].\]
In the bounded case, we have \( \overline{\text{Eik}}_{L}^s \subset \mathfrak{M} \) (the closure in the strong operator topology). The elements of this closure are also called *eikonals*.

The set \( \overline{\text{Eik}}_{L}^s \) is partially ordered: for two eikonals \( E, E' \), we write \( E \leq E' \) if \( (Ex, x) \leq (E'x, x), \ x \in \mathcal{H} \). An eikonal \( E \) is *maximal* if \( E \leq E' \) implies \( E = E' \). By \( \Omega_{L}^{\text{eik}} \subset \overline{\text{Eik}}_{L}^s \) we denote the set of maximal eikonals.

**Lemma 1** In the bounded case, the set \( \Omega_{L}^{\text{eik}} \) is nonempty.

**Proof.** By the boundedness, any totally ordered family of eikonals \( \{E_j\} \) has an upper bound \( s\lim E_j \), which is also an eikonal. Hence, the Zorn lemma implies \( \Omega_{L}^{\text{eik}} \neq \emptyset \). \( \square \)

**Definition 8.** A metric space \( \Omega_{L}^{\text{eik}} \) with the distance \( \|E - E'\| \) is called an *eikonal spectrum* of the lattice \( \mathfrak{L} \).

In the general (unbounded) case, one can regularize the eikonals as \( E_{\epsilon} := \int_0^\infty \frac{t}{1+t^2} dP_{f, \epsilon} \) (\( \epsilon > 0 \)) and deal with the corresponding spectra \( \Omega_{L}^{\text{eik}, \epsilon} \neq \emptyset \).

**Remark.** Returning to Definition 6, one more option is to define the atomic spectrum as \( (\Omega_{I_L}, \rho_{I_L}) \) or \( (\Omega_{I_L}, \sigma_{I_L}) \) (see sec 1.1, item 3). Our reserve of concrete examples is rather poor and provides no preferable choice.

### 2.2 Inflation \( I_L \)

12. Dynamical system. Let \( L \) be a semi-bounded self-adjoint operator in \( \mathcal{H} \). Without lack of generality, we assume that it is positive definite:

\[
L = L^* = \int_\mathcal{K} \lambda dQ_\lambda; \quad (Ly, y) \geq \kappa \|y\|^2, \ y \in \text{Dom} L \subset \mathcal{H},
\]

where \( dQ_\lambda \) is the spectral measure of \( L \), \( \kappa > 0 \) is a constant.

Operator \( L \) governs the evolution of a dynamical system

\[
v_{tt} + Lv = h, \quad t > 0 \tag{2.1}
\]

\[
v_{|t=0} = v^i_{|t=0} = 0, \tag{2.2}
\]

where \( h \in L^2_{\text{loc}}((0, \infty); \mathcal{H}) \) is a \( \mathcal{H} \)-valued function of time (control). Its solution \( v = v^h(t) \) is represented by the Duhamel formula

\[
v^h(t) = \int_0^t L^{\frac{3}{2}} \sin \left[ (t-s)L^{\frac{1}{2}} \right] h(s) ds = \int_0^t ds \int_0^\infty \sin \frac{\sqrt{\lambda}(t-s)}{\sqrt{\lambda}} dQ_\lambda h(s), \quad t \geq 0 \tag{2.3}
\]
In system theory, \( v^h \) is referred to as a trajectory; \( v^h(t) \in H \)

is a state at the moment \( t \). In applications, \( v^h \) describes a wave initiated by

a source \( h \).

Fix a subspace \( A \subseteq H \). The set \( \mathcal{V}_A := \{ v^h(t) \mid h \in L^\infty_2 ((0, \infty); A) \} \) of

all states produced by \( A \)-valued controls is called reachable (at the moment \( t \), from the subspace \( A \)). Reachable sets increase: \( A \subseteq B \) and \( s \leq t \) imply \( \mathcal{V}_A^s \subseteq \mathcal{V}_B^t \).

**13. Dynamical inflation.** With the system \((2.1), (2.2)\) one associates a

map \( I_L : \mathcal{L}(H) \rightarrow \mathcal{F}_\mathcal{L}(H) \), \( (I_L A)(0) := A \), \( (I_L A)(t) := \mathcal{V}_A \), \( t > 0 \).

**Lemma 2** \( I_L \) is an inflation.

**Proof.** The relation \( (I_L A)(s) \subseteq (I_L B)(t) \) as \( A \subseteq B \) and \( 0 < s \leq t \) is a

consequence of the general properties of reachable sets. The only fact we need to verify is that the map extends subspaces: \( A \subseteq (I_L A)(t) \), \( t > 0 \).

By \( \chi_{[a,b]} \) we denote the indicator of the segment \([a,b] \subseteq \mathbb{R} \).

Fix an \( r > 0 \) and \( \varepsilon \in (0, r) \). Define the functions \( \varphi_\varepsilon(t) := \varepsilon^{-2} \chi_{[-\varepsilon, \varepsilon]}(t) \text{sign}(-t) \) and \( \varphi_\varepsilon^r(t) := \varphi_\varepsilon(t-r+\varepsilon) \) for \( t \in \mathbb{R} \). Note that \( \int_0^r \varphi_\varepsilon(t) f(t) dt \rightarrow -f'(r) \) as \( \varepsilon \rightarrow 0 \)

for a smooth \( f \), i.e., \( \varphi_\varepsilon^r(t) \) converges to \( \delta'(t-r) \) as a distribution.

For \( \lambda > 0 \), define a function

\[
\psi_\varepsilon(\lambda) := \int_0^r \frac{\sin[\sqrt{\lambda}(r-t)]}{\sqrt{\lambda}} \varphi_\varepsilon^r(t) dt = \frac{2 \cos(\sqrt{\lambda} \varepsilon) - \cos(\sqrt{\lambda} 2 \varepsilon) - 1}{\varepsilon^2 \lambda}.
\]

Note that \( \psi_\varepsilon(\lambda) \rightarrow 1 \) as \( \varepsilon \rightarrow 0 \) uniformly w.r.t. \( \lambda \) in any segment \([\kappa, N]\).

Take a nonzero \( y \in A \) and consider \((2.1), (2.2)\) with the control \( h_\varepsilon(t) = \varphi_\varepsilon^r(t) y \). By the properties of \( \psi_\varepsilon \) one has

\[
\| y - v_{h_\varepsilon}^r(r) \|^2 = \langle \text{see (2.3.)} \rangle = \left\| y - \int_0^r dt \int_\kappa^\infty \sin[\sqrt{\lambda}(r-t)] \sqrt{\lambda} dQ_\lambda[\varphi_\varepsilon^r(t) y] \right\|^2 = \\
\left\| y - \int_\kappa^\infty \psi_\varepsilon(\lambda) dQ_\lambda y \right\|^2 = \left\| \int_\kappa^\infty [1 - \psi_\varepsilon(\lambda)] dQ_\lambda y \right\|^2 = \\
\int_\kappa^\infty |1 - \psi_\varepsilon(\lambda)|^2 \|Q_\lambda y\|^2 \rightarrow 0.
\]

\(^9\)For \( \kappa \leq 0 \), problem \((2.1), (2.2)\) is also well defined but the representation \((2.3)\) is of slightly more complicated form.
The order of integration change is easily justified by the Fubini Theorem. Thus, \( y = \lim_{\epsilon \to 0} v^{h_{\epsilon}}(r) \), whereas \( v^{h_{\epsilon}}(r) \in (I_L A)(r) \) holds. Since \((I_L A)(r)\) is closed in \( \mathcal{H} \), we get \( y \in (I_L A)(r) \). Hence, \( A \subseteq (I_L A)(r), \ r > 0 \). □

So, each positive definite operator \( L \) determines the inflation \( I_L \), which we call a dynamical inflation.

### 2.3 Space \( \Omega_{L_0} \).

#### 14. Lattice \( L_{L,D} \) and spectra.

Fix a subspace \( D \in \mathcal{L}(\mathcal{H}) \) and say it to be a directional subspace.

Return to the system (2.1)–(2.2). Introduce the class \( \mathcal{M}_D := \{ h \in C^\infty([0, \infty); D) \mid \text{supp} \ h \subset (0, \infty) \} \) of smooth \( D \)-valued controls vanishing near \( t = 0 \). This class determines the sets

\[
U^t_D := \left\{ h(t) - v''(t) \left\vert h \in \mathcal{M}_D \right. \right\} = \langle \text{see (2.3)} \rangle = \left\{ h(t) - \int_0^t \frac{1}{2} L^{-\frac{1}{2}} \sin \left( (t-s) L^\frac{1}{2} \right) h''(s) \, ds \bigg\vert h \in \mathcal{M}_D \right\}, \quad t \geq 0, \quad (2.4)
\]

where \( \langle \cdot \rangle := \frac{d}{dt} \). These sets are also called reachable. As one can show, the sets \( U^t_D \) increase as \( t \) grows.

**Definition 9.** The family of subspaces \( u_{L,D} = \{U^t_D\}_{t \geq 0} \subseteq \mathcal{L}(\mathcal{H}) \) is called a boundary nest.

The boundary nest determines the lattice \( \mathcal{L}_{L,D} := \mathcal{L}[I_L, u_{L,D}] \), which is the minimal \( I_L \)-invariant sublattice in \( \mathcal{L}(\mathcal{H}) \) containing \( u_{L,D} \) (item 10).

The lattice determines the spectra \( \Omega_{\mathcal{L}_{L,D}}^L \) and \( \Omega_{\mathcal{L}_{L,D}}^{rest} \). In the bounded case, the spectrum \( \Omega_{\mathcal{L}_{L,D}}^{eik} \) is also well defined (item 11).

#### 15. Lattice \( \mathcal{L}_{L_0} \) and spectra.

Let \( L_0 \) be a closed densely defined symmetric semi-bounded operator with nonzero defect indexes \( n_{\pm} = n \leq \infty \). As is easy to see, such an operator is necessarily unbounded. For the sake of simplicity, we assume it to be positive definite: \( (L_0 y, y) \geq \kappa \|y\|^2, \ y \in \text{Dom}L_0 \) with \( \kappa > 0 \).

Let \( L \) be the Friedrichs extension of \( L_0 \), so that \( L = L^* \geq \kappa I \) and \( L_0 \subset L \subset L_0^* \) holds [8]. Also, note that \( 1 \leq \dim \ker L_0^* = n \leq \infty \).

With the operator \( L_0 \) one associates two objects: the inflation \( I_L \) and the directional subspace \( D = \ker L_0^* \). This pair determines the boundary nest
$u_{L_0} := u_{L, \ker L_0}^* = \{ U^t_{\ker L_0} \}_{t \geq 0}$ and the lattice $\mathfrak{L}_{L_0} := \mathfrak{L}_{L, \ker L_0}^*$. The nest and lattice determine the corresponding spectra, and we arrive at the key subject of the paper.

**Definition 10.** The space $\Omega_{L_0} := \Omega_{\mathfrak{L}_{L_0}}$ is called a wave spectrum of the (symmetric semi-bounded) operator $L_0$.

Recall that $\Omega_{L_0}$ is endowed with the ‘interaction time’ topology (item 3).

By analogy with the latter definition, one can introduce the metric spaces $\Omega_{\text{nest}}^{L_0} := \Omega_{\mathfrak{L}_{L_0}}$ and, in the bounded case, $\Omega_{L_0}^{eik} := \Omega_{\mathfrak{L}_{L_0}}^{eik}$, which are also determined by $L_0$.

As is evident from their definitions, the spectra are unitary invariants of the operator.

**Proposition 10** If $U : \mathcal{H} \to \tilde{\mathcal{H}}$ is a unitary operator and $\tilde{L}_0 = U L_0 U^*$ then $\Omega_{L_0}$ is homeomorphic to $\Omega_{\tilde{L}_0}$. If $\mathcal{H} = \mathcal{H}_1 \oplus \mathcal{H}_2$ and $L_0 = L_1 \oplus L_2$ then $\Omega_{L_0} = \Omega_{L_1} \cup \Omega_{L_2}$.

These properties motivate the use of term ‘spectrum’. The same properties occur for $\Omega_{\text{nest}}^{L_0}$ and $\Omega_{L_0}^{eik}$, replacing ‘homeomorphic’ with ‘isometric’.

**16. Structures on $\Omega_{L_0}$.** The boundary nest $u_{L_0}$ can be regarded as an element (function) of the space $\mathcal{F}_{\mathfrak{L}(\mathcal{H})}$. As such, it can be compared with the atoms, which constitute the wave spectrum $\Omega_{L_0} \subset \mathcal{F}_{\mathfrak{L}(\mathcal{H})}$.

**Definition 11.** The set $\partial \Omega_{L_0} := \{ \alpha \in \Omega_{L_0} \mid \alpha \leq u_{L_0} \}$ is said to be the boundary of $\Omega_{L_0}$.

Also, it is natural to put $\partial \Omega_{\text{nest}}^{L_0} := \partial \Omega_{L_0}$. In the bounded case, one introduces the boundary eikonal $E^\theta = \int_0^\infty t P^t_{t \ker L_0}$ and defines $\partial \Omega_{L_0}^{eik} = \{ E \in \Omega_{L_0}^{eik} \mid E \geq E^\theta \}$ (see [3]).

There is a way to represent elements of $\mathcal{H}$ as ‘functions’ on the wave spectrum.

Fix an atom $\alpha \in \Omega_{L_0} : \alpha = \alpha(t), t \geq 0$. Let $P^t_{\alpha} := P_{\alpha(t)}$ be the corresponding projections. For $f, g \in \mathcal{H}$, we put $f \overset{\alpha}{=} g$ if there is $\varepsilon = \varepsilon(f, g, \alpha) > 0$ such that $P^t_{\alpha} f = P^t_{\alpha} g$ as $t < \varepsilon$. The relation $\overset{\alpha}{=} \overset{\alpha}{=}$ is an equivalence. The equivalence class $[f]_{\alpha} := G^f(\alpha)$ is called a wave germ (of the element $f$ at the atom $\alpha$). 

---

10 Recall that $\alpha \leq u_{L_0}$ in $\mathcal{F}_{\mathfrak{L}(\mathcal{H})}$ means that $\alpha(t) \subseteq \mathring{U}$ holds for $t \geq 0$. 
Definition 12. The germ-valued function $G^f : \alpha \mapsto [f]_\alpha, \alpha \in \Omega_{L_0}$ is called a wave image of the element $f$.

The collection $\mathcal{G} := \{G^f \mid f \in \mathcal{H}\}$ is a linear space w.r.t. the point-wise algebraic operations: $(\lambda G^f + \mu G^g)(\alpha) := [\lambda f + \mu g]_\alpha, \alpha \in \Omega_{L_0}$. The linear map $\mathcal{I} : \mathcal{H} \ni f \mapsto G^f \in \mathcal{G}$ is called an image operator.

3 DSBC

3.1 Green system

17. Ryzhov’s axioms. Consider a collection \{$\mathcal{H}, \mathcal{B}; A, \Gamma_0, \Gamma_1$\} of separable Hilbert spaces $\mathcal{H}$ and $\mathcal{B}$, and densely defined operators $A : \mathcal{H} \to \mathcal{H}$ and $\Gamma_k : \mathcal{H} \to \mathcal{B}$ ($k = 0, 1$) connected via the Green formula

$$(Au, v)_\mathcal{H} - (u, Av)_\mathcal{H} = (\Gamma_0 u, \Gamma_1 v)_\mathcal{B} - (\Gamma_1 u, \Gamma_0 v)_\mathcal{B}.$$ 

The space $\mathcal{H}$ is called an inner space; $\mathcal{B}$ and $\Gamma_k$ are referred to as a boundary values space and the boundary operators respectively [14]. Such a collection is said to be a Green system.

The following additional conditions are imposed.

R1. Dom $\Gamma_k \supseteq$ Dom $A$ holds. The restriction $A|_{\text{Ker} \Gamma_0 \cap \text{Ker} \Gamma_1} =: L_0$ is a densely defined symmetric positive definite operator with nonzero defect indexes. The relation $\overline{A} = L_0^*$ is valid (’bar’ is the operator closure).

R2. The restriction $A|_{\text{Ker} \Gamma_0} =: L$ coincides with the Friedrichs extension of $L_0$, so that we have $L_0 \subset L \subset L_0^* = \overline{A}$. Operator $L^{-1}$ is bounded and defined on $\mathcal{H}$.

R3. The subspaces $\mathcal{A} := \text{Ker} A$ and $\mathcal{D} := \text{Ker} L_0^*$ are such that the relations $\overline{\mathcal{A}} = \mathcal{D}$ and $\Gamma_0 \overline{\mathcal{A}} = \mathcal{B}$ hold.

These conditions were introduced by V.A.Ryzhov [16], which puts them as basic axioms. Note, that there are a few versions of such an axiomatics but the one proposed in [16] is most relevant for applications to forward and inverse multidimensional problems of mathematical physics.

The following consequences are derived from R1-4 [16].

C1. The operator $\Pi := (\Gamma_1 L^{-1})^* : \mathcal{B} \to \mathcal{H}$ is bounded. The set Ran $\Pi$ is dense in $\mathcal{D}$.

C2. The representation $\mathcal{A} = \{y \in \text{Dom} A \mid \Pi \Gamma_0 y = y\}$ is valid.
C3. Since $L$ is the extension of $L_0$ by Friedrichs, the relations $\text{Dom} L_0 = L^{-1}[\mathcal{H} \ominus \mathcal{D}]$ and $L_0 = L|_{L^{-1}[\mathcal{H} \ominus \mathcal{D}]}$ easily follows from the definition of such an extension (see \cite{8}).

18. Illustration. Let $\Omega$ be a $C^\infty$-smooth compact Riemannian manifold with the boundary $\Gamma$, $\Delta$ the (scalar) Beltrami-Laplace operator in $\mathcal{H} := L_2(\Omega)$, $\nu$ the outward normal on $\Gamma$, $\mathcal{B} := L_2(\Gamma)$. Denote $A = -\Delta|_{H^2(\Omega)}$, $\Gamma_0 u = u|_\Gamma$, $\Gamma_1 u = \partial_\nu u|_\Gamma$, so that $\Gamma_{0,1}$ are the trace operators. The collection $\{\mathcal{H}, \mathcal{B}; A, \Gamma_0, \Gamma_1\}$ is a Green system. Other operators, which enter in Ryzhov’s axiomatics, are the following:

- $L_0 = -\Delta|_{H^2_0(\Omega)}$ is the minimal Laplacian that coincides with the closure of $-\Delta|_{C^\infty_0(\Omega)}$
- $L = -\Delta|_{H^2(\Omega) \cap H^1_0(\Omega)}$ is the self-adjoint Dirichlet Laplacian
- $L^*_0 = -\Delta|_{\{y \in \mathcal{H} | \Delta y \in \mathcal{H}\}}$ is the maximal Laplacian
- $\mathcal{A} = \{y \in H^2(\Omega) | \Delta y = 0\}$ is the set of harmonic functions of the class $H^2(\Omega)$
- $\mathcal{D} = \{y \in \mathcal{H} | \Delta y = 0\}$ is the subspace of all harmonic functions in $L_2(\Omega)$
- $\Pi : \mathcal{B} \to \mathcal{H}$ is the harmonic continuation operator (the Dirichlet problem solver): $\Pi \varphi = u$ is equivalent to $\Delta u = 0$ in $\Omega$, $u|_\Gamma = \varphi$.

3.2 Evolutionary DSBC

19. Dynamical system. The Green system determines an evolutionary dynamical system with boundary control

$$u_{tt} + Au = 0 \quad \text{in } \mathcal{H}, \quad 0 < t < \infty \quad (3.1)$$
$$u|_{t=0} = u_t|_{t=0} = 0 \quad \text{in } \mathcal{H} \quad (3.2)$$
$$\Gamma_0 u = f(t) \quad \text{in } \mathcal{B}, \quad 0 \leq t < \infty, \quad (3.3)$$

where $f$ is a boundary control, $u = u^f(t)$ is the solution (wave). The space of controls $\mathcal{F} = L_2^{loc}(0, \infty); \mathcal{B})$ is said to be outer.

Assign $f$ to a class $\mathcal{F}_+ \subset \mathcal{F}$ if it belongs to $C^\infty([0, \infty); \mathcal{B})$, takes the values in $\Gamma_0 \text{Dom } A \subset \mathcal{B}$, and vanishes near $t = 0$, i.e., satisfies $\text{supp } f \subset (0, \infty)$. Also, note that $f \in \mathcal{F}_+$ implies $\Pi (f(\cdot)) \in \mathcal{M}_D$ (see item 14).

\footnote{$H^k$ are the Sobolev classes; $H^2_0(\Omega) = \{y \in H^2(\Omega) | y = |\nabla y| = 0 \text{ on } \Gamma\}$; $\partial_\nu$ is the differentiation w.r.t. the outward normal on $\Gamma$.}
Lemma 3 For $f \in \mathcal{F}_+$, the classical solution $u^f$ to problem (3.1) – (3.3) is represented in the form

$$u^f(t) = h(t) - \int_{0}^{t} L^{-\frac{1}{2}} \sin \left[ (t-s)L^{\frac{1}{2}} \right] h''(s) \, ds, \quad t \geq 0$$

with $h := \Pi (f(\cdot)) \in \mathcal{M}_D$.

Proof. Introducing a new unknown $w = w^f(t) := u^f(t) - \Pi (f(t))$ and taking into account C1 (item 17), we easily get the system

$$w_{tt} + Aw = -\Pi (f_t(t)) \quad \text{in } \mathcal{H}, \quad 0 < t < \infty$$

$$w|_{t=0} = w_t|_{t=0} = 0 \quad \text{in } \mathcal{H}$$

$$\Gamma_0 w = 0 \quad \text{in } \mathcal{B}, \quad 0 \leq t < \infty.$$  

With regard to the definition of the operator $L$ (see the axiom R2), this problem can be rewritten in the form

$$w_{tt} + Lw = -h_{tt} \quad \text{in } \mathcal{H}, \quad 0 < t < \infty$$

$$w|_{t=0} = w_t|_{t=0} = 0 \quad \text{in } \mathcal{H}$$

and then solved by the Duhamel formula

$$w^f(t) = -\int_{0}^{t} L^{-\frac{1}{2}} \sin \left[ (t-s)L^{\frac{1}{2}} \right] h''(s) \, ds.$$  

Returning back to $u^f = w^f + \Pi f$, we arrive at (3.4). □

20. Reachable sets. The sets

$$U^+_t := \{ u^f(t) \mid f \in \mathcal{F}_+ \} = \langle \text{see (3.4)} \rangle =$$

$$\left\{ h(t) - \int_{0}^{t} L^{-\frac{1}{2}} \sin \left[ (t-s)L^{\frac{1}{2}} \right] h''(s) \, ds \right\}, \quad t \geq 0$$

are said to be reachable from boundary.

The Green system, which governs the DSBC, determines the certain pair $L, \mathcal{D}$, which in turn determines the family $\{U^+_t\}$ by (2.4). Comparing (2.4) with (3.4), we easily conclude that the embedding $U^+_t \subset U^+_D$ holds. Moreover, the density properties R3 (item 17) enable one to derive $U^+_t = U^+_D$, $t \geq 0$. 
It is the latter relation, which inspires the definition (2.4) and motivates the terms ‘reachable sets’, ‘boundary nest’, etc in the general case (item 14), where neither boundary value space nor boundary operators are defined.

21. Illustration. Return to the item 19. The DSBC (3.1)–(3.3) associated with the Riemannian manifold is governed by the wave equation and is of the form

\[
\begin{align*}
  u_{tt} - \Delta u &= 0 \quad \text{in } \Omega \times (0, \infty) \quad (3.6) \\
  u_{t=0} &= u_t|_{t=0} = 0 \quad \text{in } \Omega \quad (3.7) \\
  u|_{\Gamma} &= f(t) \quad \text{for } 0 \leq t < \infty \quad (3.8)
\end{align*}
\]

with a boundary control \( f \in \mathcal{F} = L_2^{loc}((0, \infty); L_2(\Gamma)) \). The solution \( u = u^f(x, t) \) describes a wave, which is initiated by boundary sources and propagates from the boundary into the manifold with the speed 1. For \( f \in \mathcal{F}_+ = C^{\infty}([0, \infty); C^{\infty}(\Gamma)) \) provided \( \text{supp } f \subset (0, \infty) \), the solution \( u^f \) is classical.

By the finiteness of the wave propagation speed, at a moment \( t \) the waves fill a near-boundary subdomain \( \Gamma^t := \{ x \in \Omega \mid \text{dist } (x, \Gamma) < t \} \). Correspondingly, the reachable sets \( \mathcal{U}^t_+ \) increase as \( t \) grows and the relation \( \mathcal{U}^t_+ \subset \mathcal{H} \Gamma^t, \ t \geq 0 \) holds \(^{12}\). Closing in \( \mathcal{H} \), we get \( \overline{\mathcal{U}^t_+} \subseteq \mathcal{H} \Gamma^t, \ t \geq 0 \).

So, if the pair \( L, \mathcal{D} \) (or, equivalently, the operator \( L_0 \)) appears in the framework of a Green system, then \( \{ \mathcal{U}^t_+ \} \) introduced by the general definition (2.4) can be imagine as the sets of waves produced by boundary controls. The question arises: What is the meaning of the corresponding wave spectrum \( \Omega_{L, \mathcal{D}} (= \Omega_{L_0}) \)? In a sense, it is the question, which this paper is written for. The answer (section 3) is that, in generic cases, \( \Omega_{L_0} \) is identical to \( \Omega \).

22. Boundary controllability. Return to the abstract DSBC (3.1)--(3.3) and define its certain property. Begin with the following observation. Since the class of controls \( \mathcal{F}_+ \) satisfies \( \frac{d}{dt} \mathcal{F}_+ = \mathcal{F}_+ \), the reachable sets (3.5) satisfy \( A\mathcal{U}^t_+ = \mathcal{U}^t_+ \). Indeed, taking \( f \in \mathcal{F}_+ \) we have

\[
  Au^f(t) = \langle \text{see (3.1)} \rangle = -u^f_{tt}(t) = u^{-f''}(t) \in \mathcal{U}^t_+.
\]

By the same relations, \( u^f(t) = Au^g(t) \) holds with \( g = -(\int_0^t f) f \in \mathcal{F}_+ \). Hence, the sets \( \mathcal{U}^t_+ \) reduce the operator \( A \) and its parts \( A|_{\mathcal{U}^t_+} \) are well defined.

\(^{12}\)Geometric subspaces \( \mathcal{H}A \) are defined in item 8.
Definition 13. The DSBC (3.1)–(3.3) is said to be controllable from boundary at the time $t = T$ if $A_{|U_T} = A$ holds, i.e., one has
\[ \{\{u^I(T), Au^I(T)\} \mid f \in \mathcal{F}_+\} = \text{graph } A = \langle \text{see R1} \rangle = \text{graph } L_0^*. \] (3.10)

Controllability means two things. First, since $A$ is densely defined in $\mathcal{H}$, the equality (3.10) implies $U_T = H$, $t \geq T$, i.e., for large times the reachable sets become rich enough (dense in $\mathcal{H}$). Second, the ‘wave part’ $A_{|U_T}$ of the operator $A$, which governs the evolution of the system, represents the operator in substantial.

In applications to problems in bounded domains, such a property ‘ever holds’ (typically, for large enough times $T$). In particular, the system (3.1)–(3.6) is controllable from boundary for any $T > \max_{x \in \Omega} \text{dist } (x, \Gamma)$ [2], [4].

Let us represent the property (3.10) in the form appropriate for what follows.

Restrict the system (3.1)–(3.3) on a finite time interval $[0, T]$. Define the Hilbert space of controls $\mathcal{F}_T = L_2([0, T]; \mathcal{B})$ and the corresponding smooth class $\mathcal{F}_T^+ \subset \mathcal{F}_T$.

Introduce a control operator $W_T : \mathcal{F}_T \to \mathcal{H}$, $\text{Dom } W_T = \mathcal{F}_T^+$, $W_T f := u^I(T)$. Let $W^T = U^T |W^T|$ be its polar decomposition, where $|W^T| := ((W^T)^*W^T)^{\frac{1}{2}}$ acts in $\mathcal{F}_T$, and $U^T$ is an isometry from $\text{Ran } |W^T| \subset \mathcal{F}_T$ onto $\text{Ran } W^T \subset \mathcal{H}$ (see, e.g., [8]).

Lemma 4 If the DSBC (3.1)–(3.3) is controllable at $t = T$ then the relation \[ \{\{|W^T|f, |W^T|(-f'')\} \mid f \in \mathcal{F}_+\} = \text{graph } L_0^*U_T \] holds.

Proof. Represent (3.10) in the equivalent form \[ \{\{|W^T|f, |W^T|(-f'')\} \mid f \in \mathcal{F}_+\} = \text{graph } L_0^*. \] Since $\text{Ran } U^T = U_T^* = \mathcal{H}$, the isometry $U^T$ is a unitary operator. Applying it to the latter representation, one gets the assertion of the lemma. □

As a consequence, we conclude the following.

Proposition 11 If the DSBC (3.1) – (3.3) is controllable at $t = T$ then the operator $|W^T|$ determines the operator $L_0^*$ up to unitary equivalence.

23. Response operator. In the DSBC (3.1)–(3.3) restricted on $[0, T]$, an ‘input–output’ correspondence is described by the response operator $R^T : \mathcal{F}_T \to \mathcal{F}_T$, $\text{Dom } R = \mathcal{F}_T^+$, $(R^T f)(t) := \Gamma_1 \left( u^I(t) \right) , 0 \leq t \leq T$.

\[ ^{13} \text{Below the closure is taken in } \mathcal{H} \times \mathcal{H}; \text{ graph } A := \{\{y, Ay\} \mid y \in \text{Dom } A\}. \]
Illustration. The response operator of the DSBC (3.6)–(3.8) is \( R^T : f \mapsto \partial_\nu u^f |_{\Gamma \times [0,T]} \).

The key fact of the BC-method is that the operator \( R^2T \) determines the operator \( C^T := \left( W^T \right)^* W^T \) through an explicit formula [2], [3], [4].

**Proposition 12** The representation \( C^T = \frac{1}{2} \left( S^T \right)^* R^2T J^2T S^T \) holds, where the operator \( S^T : \mathcal{F}^T \to \mathcal{F}^{2T} \) extends controls from \([0,T]\) to \([0,2T]\) by oddness w.r.t. \( t = T \), \( J^2T : \mathcal{F}^{2T} \to \mathcal{F}^{2T} \), \( (J^2T f)(t) = \int_0^t f(s) \, ds \).

Hence, \( R^{2T} \) determines the modulus \( \left| W^T \right| = \left( C^T \right)^{\frac{1}{2}} \). By Proposition 11 we conclude that \( R^{2T} \) determines the operator \( L_0^* \) up to unitary equivalence. Since \( L_0 = L_0^{**} \), we arrive at the following basic fact.

**Proposition 13** If the DSBC (3.1) - (3.3) is controllable from boundary at \( t = T \) then its response operator \( R^{2T} \) determines the operator \( L_0 \) up to unitary equivalence.

24. Illustration. The system (3.6) – (3.8) is also controllable from boundary. Such a property is a partial case of the following general fact.

Return to the system (2.1)–(2.1). In our case, the operator \( L \) governing its evolution is the Dirichlet Laplacian \(-\Delta\) (item 18). Fix a set \( A \in \mathcal{O}^{\text{reg}} \). The reachable sets \( \mathcal{V}_{HA}^t \) consist of the waves produced by sources supported in \( A \subset \Omega \). Since the waves propagate with unit velocity, the embedding \( \mathcal{V}_{HA}^t \subseteq \mathcal{H}^A \) holds evidently. The character of this embedding is a subject of control theory of hyperbolic PDE.

The principal result is that the relation \( \mathcal{V}_{HA}^t = \mathcal{H}^A \) is valid for any \( A \in \mathcal{O}^{\text{reg}} \) and \( t \geq 0 \). It is derived from the fundamental Holmgren-John-Tataru uniqueness theorem (see, e.g., [2], [4]). In control theory this property is referred to as a local controllability of manifolds. In notation of item 13, it takes the form: \( (I_L \mathcal{H}A)(t) = \mathcal{H}A^t \) holds for any \( A \in \mathcal{O}^{\text{reg}} \), \( t \geq 0 \). Since \( \mathcal{H}A^t = (iM\mathcal{H}A)(t) \) by the definition of metric inflation on \( \mathcal{H} \) (item 8), we arrive at the following formulation of the local controllability.

**Proposition 14** The inflations \( I_L \) and \( iM \) coincide on the lattice \( \mathcal{H} \).

Return to the system (3.6)–(3.8) and the embedding \( \mathcal{U}_D^t \subseteq \mathcal{H}^{t'} \) (item 21). The same HJT-theorem implies the equality \( \mathcal{U}_D^t = \mathcal{H}^{t'} \), \( t \geq 0 \), which is referred to as a local boundary controllability of the manifold \( \Omega \).
Recall that the boundary nest \( u_{L_0} = \{ \overline{U^T_D} \}_{t \geq 0} \) \( (D = \text{Ker}L_0^*) \) is defined in item 15. Let \( b = \{ \Gamma^t \}_{t \geq 0} \subset \mathcal{O}_{\text{reg}} \) be the family of metric neighborhoods of the boundary \( \Gamma \). Denote \( [b] = \{ [\Gamma^t] \}_{t \geq 0} \subset \mathfrak{R} \) (items 7,8). Boundary controllability of \( \Omega \) is equivalent to the following.

**Proposition 15** The relation \( i[\Gamma^T] = \overline{U^T_D}, \ t \geq 0 \) holds. Hence, \( i[b] = u_{L_0} \).

Boundary controllability implies the following. Since the family \( \{ \Gamma^t \} \) exhausts \( \Omega \) for any \( T \geq T_* \) \( := \sup_{x \in \Omega} d(x, \Gamma) \), the boundary nest \( \{ \overline{U^T_D} \}_{t \leq T} \) exhausts the space \( \mathcal{H} \) as \( T \geq T_* \). By this, the system \((3.6)-(3.8)\) turns out to be controllable as \( T \geq T_* \) \cite{[2],[4]}.

Hence, by Proposition 13, given for a fixed \( T \geq 2T_* \) the response operator \( R^T \) of the system \((3.6)-(3.8)\) determines the minimal Laplacian \( L_0 \) up to unitary equivalence.

### 3.3 Stationary DSBC

25. **Weyl function.** Here we follow the paper \cite{[16]}, and deal with the same Green system \( \{ \mathcal{H}, \mathcal{B}; A, \Gamma_0, \Gamma_1 \} \) and the associated operators \( L_0, L \) (item 17).

The problem

\[
(A - z\mathbb{I})u = 0 \quad \text{in } \mathcal{H}, \ z \in \mathbb{C} \\
\Gamma_0 u = \varphi \quad \text{in } \mathcal{B}
\]

(3.11) \hspace{1cm} (3.12)

is referred to as a stationary DSBC. For \( \varphi \in \Gamma_0\text{Dom }A \) and \( z \in \mathbb{C} \setminus \text{spec }L \), such a problem has a unique solution \( u = u^\varphi_z \), which is a \( \text{Dom }A \)-valued function of \( z \).

The ‘input–output’ correspondence in the system \((3.11)-(3.12)\) is realized by an operator-valued function \( W(z) : \mathcal{B} \to \mathcal{B}, W(z)\varphi := \Gamma_1 u^\varphi_z \ (z \notin \text{spec }L) \). It is called the Weyl function and plays the role of data in frequency domain inverse problems.

The following important fact is established in \cite{[16]}. Recall that a symmetric operator in \( \mathcal{H} \) is said to be completely non-selfadjoint if there is no subspace in \( \mathcal{H} \), in which the operator induces a self-adjoint part.

**Proposition 16** If the Green system is such that the operator \( L_0 \) is completely non-selfadjoint, then the Weyl function determines the operator \( L_0 \) up to unitary equivalence.
26. Illustration. Return to item 17. The DSBC (3.11)–(3.12) associated with the Riemannian manifold is

\[(A + z)u = 0 \quad \text{in } \Omega \quad (3.13)\]
\[u|_{\Gamma} = \phi, \quad (3.14)\]

where \(A = -\Delta|_{H^2(\Omega)}\).

Lemma 5 The operator \(L_0 = -\Delta|_{H^2(\Omega)}\) is completely non-selfadjoint.

Proof. Assume that there exists a subspace \(K \subset H\) such that the operator \(L_0^K := -\Delta|_{K \cap H^2(\Omega)} \neq 0\) is self-adjoint in \(K\). In the mean time, \(L_0^K\) is a part of \(L\), which is a self-adjoint operator with the discrete spectrum. Hence, spec \(L_0^K\) is also discrete; each of its eigenfunctions satisfies \(-\Delta \phi = \lambda \phi\) in \(\Omega\) and belongs to \(H^2(\Omega)\). The latter implies \(\phi = \partial_\nu \phi = 0\) on \(\Gamma\). This leads to \(\phi \equiv 0\) by the well-known E.Landis uniqueness theorem for solutions to the Cauchy problem for elliptic equations. Hence, \(L_0^K = 0\) in contradiction to the assumption. \(\square\)

The Weyl function of the system is \(W(z)\phi = \partial_\nu u^\phi|_{\Gamma} (z \notin \text{spec } L)\). By the aforesaid, the function \(W\) determines the minimal Laplacian \(L_0\) of the manifold \(\Omega\) up to unitary equivalence.

27. Spectral data. Besides the Weyl function, there is one more kind of boundary inverse boundary data associated with the DSBC (3.13)–(3.14).

Let \(\lambda_k \in \lambda_k \leq \lambda_2 \leq \lambda_3 \leq \cdots \to \infty\) be the spectrum of the Dirichlet Laplacian \(L\). Let \(\phi_k \in \{\phi_k\}^{\infty}_{k=1}: L\phi_k = \lambda_k \phi_k\) be the corresponding eigen basis in \(H\) normalized by \((\phi_k, \phi_l) = \delta_{kl}\).

The set of pairs \(\Sigma_\Omega := \{\lambda_k; \partial_\nu \phi_k|_{\Gamma}\}^{\infty}_{k=1}\) is called the (Dirichlet) spectral data of the manifold \(\Omega\).

The well-known fact is that these data determine the Weyl function and vice versa (see, e.g., [16]). Hence, \(\Sigma_\Omega\) determines the minimal Laplacian \(L_0\) up to unitary equivalence. However, such a determination can be realized not through \(W\) but in more explicit way.

Namely, let \(U : H \to \tilde{H} := l_2, Uy = \tilde{y} := \{(y, \phi_k)\}^{\infty}_{k=1}\) be the Fourier transform that diagonalizes \(L\): \(\tilde{L} := ULU^* = \text{diag} \{\lambda_1, \lambda_2, \ldots\}\). For any harmonic function \(a \in A\), its coefficients are \((a, \phi_k) = -\frac{1}{\lambda_k} \int_{\Gamma} a \partial_\nu \phi_k d\Gamma\) that can be verified by integration by parts. Therefore, the spectral data \(\Sigma_\Omega\) determine the image \(\tilde{A} := UA \subset \tilde{H}\) and its closure \(\tilde{D} = UD = \overline{\tilde{A}}\). Thus, the determination \(\Sigma_\Omega \Rightarrow \tilde{L}, \tilde{D}\) occurs.
In the mean time, the relation C3 (item 17) implies 
\( \tilde{L}_0 = U^* L_0 U = \tilde{L}|_{L^{-1} [\tilde{H} \oplus \tilde{D}]} \) by isometry of \( U \). Thus, \( \tilde{L}_0 \) is a unitary copy of \( L_0 \) constructed via the spectral data.

\section{Reconstruction of manifolds}

\subsection{Inverse problems}

\textbf{28. Setup.} In inverse problems (IP) for DSBC associated with manifolds, one needs to recover the manifold via its boundary inverse data\textsuperscript{14}. Namely,

**IP 1.** given for a fixed \( T > 2\max \text{dist} (x, \Gamma) \) the response operator \( R^T \) of the system (3.6)–(3.8), to recover the manifold \( \Omega \)

**IP 2.** given the Weyl function \( W \) of the system (3.13)–(3.14), to recover the manifold \( \Omega \)

**IP 3.** given the spectral data \( \Sigma_\Omega \), to recover the manifold \( \Omega \).

The problems are called \textit{time-domain}, \textit{frequency-domain}, and \textit{spectral} respectively.

Setting the goal to determine an unknown manifold from its boundary inverse data, we have to keep in mind the evident nonuniqueness of such a determination: all isometric manifolds with the mutual boundary have the same data. Therefore, the only reasonable understanding of ‘to recover’ is to construct a manifold, which possesses the prescribed data \textsuperscript{4}.

As we saw, the common feature of problems IP 1–3 is that their data determine the minimal Laplacian \( L_0 \) up to unitary equivalence. By this, each kind of data determines the wave spectrum \( \Omega_{L_0} \) up to isometry (see Proposition \textsuperscript{10}). As will be shown, for a wide class of manifolds the relation \( \Omega_{L_0} \xrightarrow{\text{isom}} \Omega \) holds. Hence, for such manifolds, to solve the IPs it suffices to extract a unitary copy \( \tilde{L}_0 \) from the data, find its wave spectrum \( \Omega_{\tilde{L}_0} \xrightarrow{\text{isom}} \Omega_{L_0} \), and thus get an isometric copy of \( \Omega \). It is the program for the rest of the paper.

\textbf{29. Simple manifolds.} Recall that we deal with a compact smooth Riemannian manifold \( \Omega \) with the boundary \( \Gamma \). The family \( b = \{ \Gamma^t \}_{t \geq 0} \) consists of metric neighborhoods of \( \Gamma \). Nets and dense lattices were introduced

\textsuperscript{14}In concrete applications (acoustics, geophysics, electrodynamics, etc), these data formalize the measurements implemented at the boundary.
in item 9. \( \mathcal{L}[M, b] \subset \mathcal{O}^{\text{reg}} \) is the minimal \( M \)-invariant (sub)lattice, which contains \( b \).

We say \( \Omega \) to be a \textit{simple manifold} if the lattice \( \mathcal{L}[M, b] \) is dense in \( \mathcal{O}^{\text{reg}} \).

The evident obstacle for a manifold to be simple is its symmetries. For a ball \( \Omega = \{ x \in \mathbb{R}^n \mid |x| \leq 1 \} \), the lattice \( \mathcal{L}[b, M] \) consists of sums of ‘annuluses’ of the form \( \{ x \in \Omega \mid 0 < a < |x| < b \leq 1 \} \). Surely, such a system is not a net in the ball. A plane triangle is simple if and only if its legs are pair-wise nonequal. Easily checkable sufficient conditions on the shape of \( \Omega \subset \mathbb{R}^n \), which provide the simplicity, are proposed in [1]. They are also appropriate for Riemannian manifolds and show that simplicity is a generic property: it can be provided by arbitrarily small smooth variations of the boundary \( \Gamma \).

30. Solving IPs. The following result provides reconstruction of \( \Omega \).

\textbf{Theorem 1} Let \( \Omega \) be a simple manifold, \( L_0 = -\Delta|_{H^2_0(\Omega)} \) the minimal Laplacian, \( \Omega_{L_0} \) its wave spectrum. There exists an isometry (of metric spaces) \( i_* \) that maps \( \Omega_{L_0} \) onto \( \Omega \), the relation \( i_*(\partial\Omega_{L_0}) = \Gamma \) being valid.

\textbf{Proof.} Denote \( [b] := \{ [\Gamma_t] \}_{t \geq 0} \subset \mathfrak{K} \). Let \( \mathcal{L}[M, [b]] \subset \mathfrak{K} \) be the image of \( \mathcal{L}[M, b] \) through the ‘projection’ \( A \mapsto [A] \) (item 7).

Propositions 14,15 imply \( i\mathcal{L}[M, [b]] = \mathcal{L}[iM, i[b]] = \mathcal{L}[I_L, u_{L_0}] = \mathcal{L}_{L_0} \subset \mathfrak{K}^H \).

Taking into account the simplicity condition and applying Proposition 9 to the case \( \mathcal{N} = \mathcal{L}[M, [b]] \), we conclude that \( \Omega_{L_0} \) is isometric to \( (\Omega, d) \). The isometry is realized by the bijection \( i_* : i[\alpha] \mapsto x_\alpha \).

To compare the atoms \( i[\alpha] \), which constitute \( \Omega_{L_0} \), with the boundary nest \( u_{L_0} \), is in fact to compare the metric neighborhoods \( \{ x_\alpha \}_t \) with the metric neighborhoods \( \{ \Gamma_t \} \). Since \( \{ x_\alpha \}_t \subset \Gamma_t, \ t \geq 0 \) is valid if and only if \( x_\alpha \in \Gamma \), we conclude that \( i_*(\partial\Omega_{L_0}) = \Gamma \). \( \square \)

Thus, to solve the IPs 1-3 in the case of simple \( \Omega \), it suffices to determine (from the inverse data) a relevant unitary copy \( \tilde{L}_0 \) of the minimal Laplacian, and then find its wave spectrum \( \Omega_{\tilde{L}_0} \).

31. Remarks.

\(^{15}\)Presumably, any compact manifold with trivial symmetry group is simple but it is a conjecture. In the mean time, for noncompact manifolds this is not true.
1. Regarding non-simple manifolds, note the following. If the symmetry group of \( \Omega \) is nontrivial then, presumably, \( \Omega_{L_0} \) is isometric to the properly metrized set of the group orbits. Such a conjecture is motivated by the following easily verifiable examples.

- For a ball \( \Omega = \{ x \in \mathbb{R}^n \mid |x| \leq r \} \), the spectrum \( \Omega_{L_0} \) is isometric to the segment \([0, r]\) \( \subset \mathbb{R} \). Its boundary \( \partial \Omega_{L_0} \) is identical to the endpoint \( \{0\} \).

- For an ellipse \( \Omega = \{ (x, y) \in \mathbb{R}^2 \mid \frac{x^2}{a^2} + \frac{y^2}{b^2} \leq 1 \} \), \( \Omega_{L_0} \) is isometric to its quarter \( \Omega \cap \{ (x, y) \mid x \geq 0, y \geq 0 \} \), whereas \( \partial \Omega_{L_0} \) is isometric to \( \{ (x, y) \mid \frac{x^2}{a^2} + \frac{y^2}{b^2} = 1, x \geq 0, y \geq 0 \} \).

- Let \( \omega \subset \{ (x_1, x_2) \in \mathbb{R}^2 \mid x_2 > 0 \} \) be a compact domain with the smooth boundary. Let \( \Omega \) be a torus in \( \mathbb{R}^3 \), which appears as result of rotation of \( \omega \) around the \( x_1 \)-axis. Then \( \Omega_{L_0} \) isom \( = \omega \) and \( \partial \Omega_{L_0} \) isom \( = \partial \omega \).

2. In applications a possible lack of simplicity is not an obstacle for solving problems IP 1–3 because their data not only determine a copy of \( L_0 \) but contain substantially more information about \( \Omega \). Roughly speaking, the matter is as follows. When we deal with these problems, the boundary \( \Gamma \) is given. By this, instead of the boundary nest \( u_{L_0} \) of the sets reachable from the whole \( \Gamma \) (see (3.5)), we can use the much richer family \( \{ u'_{\sigma} \}_{t \geq 0, \sigma \subset \Gamma} \) of sets reachable from any patch \( \sigma \subset \Gamma \) of positive measure \( 16 \). Therefore, even though the density of the lattice \( \mathcal{L}[L_0, u_{L_0}] \) in \( \mathcal{M}^\mathcal{H} \) may be violated by symmetries, the lattice \( \mathcal{L}[L_0, u'_{L_0}] \) is always dense. As a result, the wave spectrum corresponding to the dense lattice turns out to be isometric to \( \Omega \). The latter is the key fact, which enables one to reconstruct \( \Omega \): see [5] for detail.

3. The spectra \( \Omega_{L_0}^{\text{nest}} \) and \( \Omega_{L_0}^{\text{eik}} \) are also appropriate for reconstruction. If \( \Omega \) is simple, one has \( \Omega_{L_0} \) isom \( = \Omega_{L_0}^{\text{nest}} \) isom \( = \Omega_{L_0}^{\text{eik}} \) isom \( = (\Omega, d) \) [5], [6].

4. If \( \Omega \) is noncompact, the definition of simplicity remains to be meaningful, local controllability is in force, and \( \mathcal{H} = \cup_{t>0} \mathcal{U}_T^\mathcal{D} \) holds. One can show that the response operator \( R^T \) known for all \( T > 0 \) determines the simple manifold up to isometry. Also, defining mutatis mutandis the Weyl function and spectral data for a noncompact \( \Omega \), one can obtain the same result: these data determine the simple manifold up to isometry.

32. Algebras in reconstruction. Recall that the von Neumann algebra \( \mathfrak{N}_L \subset \mathfrak{B}(\mathcal{H}) \) associated with the lattice \( \mathcal{L} \subset \mathcal{L}(\mathcal{H}) \) was introduced in item

\[16\] More precisely, \( \mathcal{U}_T^\mathcal{D} \) consists of the solutions (waves) \( u^f(t) \) produced by the boundary controls \( f \) supported on \( \sigma \times [0, \infty) \).
11. In the bounded case, along with $\mathcal{N}_L$ one can define the algebra $\mathcal{E}_L$ as the minimal norm-closed subalgebra of $\mathcal{B}(\mathcal{H})$, which contains all maximal eikonal.

For the algebras $\mathcal{N}_{L_0} = \mathcal{N}_{\mathcal{E}_{L_0}}$ and $\mathcal{E}_{L_0} = \mathcal{E}_{\mathcal{E}_{L_0}}$ associated with manifold, the following holds [5],[6].

(i) Both of these algebras are commutative. The embedding $\mathcal{E}_{L_0} \subset \mathcal{N}_{L_0}$ is dense in the strong operator topology in $\mathcal{B}(\mathcal{H})$.

(ii) If $\Omega$ is simple then $\mathcal{E}_{L_0}$ is isometrically isomorphic to the algebra $C(\Omega)$ of continuous functions. By this, its spectrum $\hat{\mathcal{E}}_{L_0}$ is homeomorphic to $\Omega$.

These results are applied to reconstruction by the scheme $\{\text{inverse data}\} \Rightarrow \mathcal{E}_{L_0} \Rightarrow \hat{\mathcal{E}}_{L_0} \Rightarrow \Omega$ [5],[6].

Note that commutativity is derived from local controllability of the system (3.6)–(3.8). In the corresponding dynamical system on a graph, a lack of controllability occurs and, as a result, these algebras turn out to be noncommutative [18]. This leads to problems and difficulties in reconstruction, which are not overcome yet. In particular, the relations between the spectra $\Omega_{L_0}$ and $\hat{\mathcal{E}}_{L_0}$ are not clear.

4.2 Comments

33. A look at isospectrality Let $\text{spec }L = \{\lambda_k\}_{k=1}^{\infty}$ be the spectrum of the Dirichlet Laplacian on $\Omega$ (item 27). The question: "Does spec $L$ determine $\Omega$ up to isometry?" is a version of the classical M.Kac's drum problem[12]. The negative answer is well known (see, e.g., [9]) but, as far as we know, the satisfactory description of the set of isospectral manifolds is not obtained yet. The following is some observations in concern with such a description.

Assume that we deal with a simple $\Omega$. In accordance with Theorem 1, such a manifold is determined by any unitary copy $\tilde{L}_0$ of the operator $L_0 \subset L$. If the spectrum of $L$ is given, to get such a copy it suffices to possess the Fourier image $\tilde{D} = U\mathcal{D}$ of the harmonic subspace in $\tilde{\mathcal{H}} = l_2$: see C3, item 17 [19]. In the mean time, as is evident, if $\Omega$ and $\Omega'$ are isometric, then the corresponding images are identical: $\tilde{D} = \tilde{\mathcal{D}}'$. Therefore, $\Omega$ and $\Omega'$ are isospectral but not isometric if and only if $\tilde{D} \neq \tilde{\mathcal{D}}'$. In other words, the subspace $\tilde{D}$ is a relevant ‘index’, which distinguishes the isospectral manifolds.

---

[17] i.e., the set of maximal ideals of $\mathcal{E}_{L_0}$ [15].
[18] N.Wada, private communication.
[19] It is the fact, which is exploited in [1]
As an image of harmonic functions, which is admissible for the given \( \tilde{L} = \text{diag} \{ \lambda_1, \lambda_2, \ldots \} \), a subspace \( \tilde{D} \subset l_2 \) has to obey the following conditions:

1. A lineal set \( \mathcal{L}_{\tilde{D}} := \tilde{L}^{-1} \left[ l_2 \ominus \tilde{D} \right] \) is dense in \( l_2 \), whereas replacement of \( \tilde{D} \) by any wider subspace \( \tilde{D}' \supset \tilde{D} \) leads to the lack of density: \( \text{clos} \mathcal{L}_{\tilde{D}'} \neq l_2 \)

2. Extending an operator \( \tilde{L}|_{\mathcal{L}_{\tilde{D}}} \) by Friedrichs, one gets \( \tilde{L} \).

In the mean time, taking any subspace \( \tilde{D} \subset l_2 \) obeying 1,2 \( ^{20} \), one can construct a symmetric operator \( \tilde{L}_0 \) by C3, and then find its wave spectrum \( \Omega_{\tilde{L}_0} \) as a candidate to be a drum. However, the open question is whether such a ‘drum’ is human (is a manifold).

34. Wave model. Return to the abstract system (3.1)–(3.3) and assume it to be controllable at \( t = T \). Reduce the system to the interval \( 0 \leq t \leq T \). Recall that the image and control operators \( \mathcal{I} : \mathcal{H} \to \mathcal{G} \) and \( W^T : \mathcal{F}^T \to \mathcal{H} \) were introduced in items 16 and 22 respectively. The composition \( V^T := \mathcal{I}W^T : \mathcal{F}^T \to \mathcal{G} \) is called a visualizing operator \( ^{2} \), \( ^{3} \), \( ^{4} \).

Let the response operator \( R^{2T} \) be given. The following is a way to construct a canonical ‘functional’ model of the operator \( L_0^* \).

- \( R^{2T} \) determines the operator \( |W^T| \) in \( \mathcal{F}^T \) (item 23). In what follows, it is regarded as a model control operator \( \tilde{W}^T := |W^T| \), which acts from \( \mathcal{F}^T \) to a model inner space \( \tilde{\mathcal{H}} := \mathcal{F}^T \).
- Determine the operator \( \tilde{L}_0^* \) in \( \tilde{\mathcal{H}} \) as the operator of the graph \( \{ (W^T f, \tilde{W}^T(-f'')) \mid f \in \mathcal{F}^+ \} \) (Lemma 1 item 22). Find \( \tilde{L}_0 = \tilde{L}_0^{**} \).
- Find the wave spectrum \( \Omega_{\tilde{L}_0} \) and recover the germ space \( \tilde{\mathcal{G}} \) on it. Determine the image operator \( \tilde{\mathcal{I}} : \tilde{\mathcal{H}} \to \tilde{\mathcal{G}} \). Compose the visualizing operator \( \tilde{V}^T = \tilde{\mathcal{I}}W^T : \mathcal{F}^T \to \tilde{\mathcal{G}} \).
- Define \( (L_0^{\text{mod}})^* \) as an operator in \( \tilde{\mathcal{G}} \) determined by the graph \( \{ (\tilde{V}^T f, \tilde{V}^T(-f'')) \mid f \in \mathcal{F}^+ \} \).

Surely, it is just a draft\( ^{21} \) of the model and plan for future work: one needs to endow the germ space \( \tilde{\mathcal{G}} \) with relevant Hilbert space attributes. Presumably, in ‘good cases’, \( \tilde{\mathcal{G}} = L_{2,\mu}(\Omega_{\tilde{L}_0}) \). Also, the model operator is expected to be local: \( \text{supp}(L_0^{\text{mod}})^*y \subseteq \text{suppy} \), whereas the model trace operators \( \tilde{\Gamma}_{0,1} \)

\(^{20}\)such subspaces do exist (M.M.Faddeev, private communication)

\(^{21}\)Some detail see in \(^{6} \), sec 3.4.
are connected with the restriction \( y \mapsto y|_{\partial \Omega} \). Hopefully, the collection \( \{ \mathcal{G}, \mathcal{B}; (L_0^{\text{mod}})^*, \mathcal{G}_0, \mathcal{G}_1 \} \) constitutes the Green system, which is a canonical model of the original \( \{ \mathcal{H}, \mathcal{B}; A, \Gamma_0, \Gamma_1 \} \). The model is determined by \( R^{2T} \).

Such a model is in the spirit of general system theory \[13\], where it would be regarded as a realization relevant to the transfer operator function \( R^{2T} \). Remarkable point is the role of a time in its construction.

35. Open question. For any operator \( L_0 \) of the class under consideration, the lattice \( \mathfrak{L}_{L_0} \) is a well-defined object, \( \mathfrak{L}_{L_0} \neq \{0\} \) being hold. We have neither a proof nor a counterexample to the following principal conjecture: \( \Omega_{L_0} \neq \emptyset \). However, there is example of the operator \( L_0 \) such that \( \Omega_{L_0} \) consists of a single point.

36. A bit of philosophy. In applications, the external observer pursues the goal to recover a manifold \( \Omega \) via measurements at its boundary \( \Gamma \). The observer prospects \( \Omega \) with waves \( u^f \) produced by boundary controls. These waves propagate into the manifold, interact with its inner structure and accumulate information about the latter. The result of interaction is also recorded at \( \Gamma \). The observer has to extract the information about \( \Omega \) from the recorded.

By the rule of game in IPs, the manifold itself is invisible (unreachable) in principle. Therefore, the only thing the observer can hope for, is to construct from the measurements an image of \( \Omega \) possibly resembling the original. By the same rule, the only admissible material for constructing is the waves \( u^f \). To be properly formalized, such a look at the problem needs two things:

- an object that codes exhausting information about \( \Omega \) and, in the mean time, is determined by the measurements
- a mechanism that decodes this information.

Resuming our paper, the first is the minimal Laplacian \( L_0 \), whereas to decode information is to determine its wave spectrum constructed from the waves \( u^f \). It is \( \Omega_{L_0} \), which is a relevant image of \( \Omega \).

The given paper promotes an algebraic trend in the BC-method \[5\], by which to solve IPs is to find spectra of relevant lattices and algebras. An attempt to apply this philosophy to solving new problems would be quite reasonable. An encouraging fact is that in all above-mentioned unsolved

\[^{22}\text{As far as we know, the known models of symmetric operators do not possess such properties \[17\].}\]
4.3 Appendix

37. Basic lemma. Recall the notation: for a set $A \subseteq \Omega$, $\overline{A}$ is its metric closure, $\text{int} A$ is the set of interior points, $A'$ is the metric neighborhood of radius $t$, $A^0 := A$. If $A \in \mathcal{O}$ then $A \subseteq \text{int} \overline{A}$ and $\overline{A} = \text{int} \overline{A}$ holds.

Return to item 5. Let $f = f(t)$, $t \geq 0$ be an element of $M \overline{\mathcal{O}}$. Define the set $\mathcal{F} := \cap_{t>0} f(t) \subset \Omega$. Define the functions $f_\ast(t) = (Mf)(t) = f_t$ as $t > 0$, $f_\ast(0) = f(0)$ and $f^\ast(t) = \text{int} f_t, t \geq 0$.

**Lemma 6** (i) If $f \neq 0_{\mathcal{F}}$ then $\mathcal{F} = \overline{\mathcal{F}} \neq \emptyset$ and the relations $f_\ast \leq f \leq f^\ast$ hold in $\mathcal{F}$. (ii) If $f$ and $g$ satisfy $\mathcal{F} = \mathcal{G}$ then $f(t) = g(t)$ for $t \geq 0$.

**Proof.**

1. If $f \leq f_j \in M \overline{\mathcal{O}}$ then $f(t) = \cup_{j \geq 1} f_j(t), t \geq 0$. Therefore, $f_k(0) \subset \cup_{j \geq 1} f_j(0) \subset \cup_{j \geq 1} (f_j(0))^t = \cup_{j \geq 1} f_j(t) = f(t)$, $t \geq 0$. Hence, $\mathcal{F} \subset \cup_{j \geq 1} f_j(0) = \emptyset$.

2. If $f \not< f_j \in M \overline{\mathcal{O}}$ then $f(t) = \cap_{j \geq 1} f_j(t), t \geq 0$. Define a closed set $F = \cap_{j \geq 1} f_j(0) \subset \Omega$ and show that $F \neq \emptyset$.

Assume $F = \emptyset$. Since $\overline{f_{j+1}(0)} \subset f_j(0)$, for any $x \in \Omega$ and $t > 0$ there is $j_0 = j_0(x, t)$ such that $\{x\}^t \cap f_j(0)$ as $j \geq j_0$. Indeed, otherwise, by assumptions $A1, 2$, the ball $\{x\}^t$ has to contain the points of $F$. Hence, $x \notin (f_j(0))^t$ as $j > j_0$. Since $x$ is arbitrary, we have $\emptyset = \cup_{j \geq 1} (f_j(0))^t = \cup_{j \geq 1} f_j(t)$. Therefore $f(t) = \text{int} \cap_{j \geq 1} f_j(t) = \emptyset$, i.e., $f(t) = 0_{\mathcal{O}}, t \geq 0$. It means that $f = 0_{\mathcal{F}}$, a contradiction with assumptions of the lemma. So, $F \neq \emptyset$.

3. Show that $F = \hat{f}$, i.e., $F$ does not depend on $\{f_j\}$.

For every $j \geq 1$, we have $\overline{f_j(0)} = \cap_{t>0}(f_j(0))^t = \cap_{t>0} f_j(t) = \cup_{t>0} f(t) = \hat{f}$. Hence $F = \cap_{j \geq 1} f_j(0) \supset \hat{f}$.

On the other hand, the monotonicity $\overline{f_{j+1}(0)} \subset f_j(0)$ implies $F = \cap_{j \geq 1} f_j(0) \subset (\cap_{j \geq 1} f_j(0))^t \subset \cap_{j \geq 1} (f_j(0))^t$. Since the next to the last set is open as $t > 0$, we have $F \subset (\cap_{j \geq 1} f_j(0))^t \subset \text{int} \cap_{j \geq 1} (f_j(0))^t \subset \text{int} \cap_{j \geq 1}$

---

23However, the limit $f$ can depend on $\{f_j\}$: there are examples for $\Omega = \mathbb{R}^n$!
\[(f_j(0))^t \subseteq \text{int } \cap_{j \geq 1} f_j(t) = f(t) \text{ for all } t > 0. \text{ Hence } F \subseteq \cap_{t > 0} f_j(t) = \check{f}, \text{ and we arrive at } F = \check{f}.

Thus, we obtain \( F = \check{f} \neq \emptyset. \)

4. Show that \( f_* \leq f. \) Choosing \( MO \ni f_j \searrow f, \) for \( t > 0 \) one has \( \check{f}^t = F^t \subseteq (f_j(0))^t = (f_j(0))^t = f_j(t). \) This implies \( f^t \subseteq \cap_{j \geq 1} f_j(t). \) Since \( f^t \) is an open set, the embedding \( f^t \subseteq \text{int } \cup_{j \geq 1} f_j(t) = f(t) \) holds. The latter means that \( f_*(t) \leq f(t) \) in \( O \) as \( t > 0. \) The definition of \( f_* \) at \( t = 0 \) leads to \( f_*(t) \leq f(t), t > 0 \) in \( O, \) i.e., \( f_* \leq f \) in \( F_O. \)

Show that \( f \leq f^*. \) Choose \( MO \ni f_j \searrow f \) that means \( f(t) = \text{int } \cap_{j \geq 1} f_j(t), t \geq 0. \) For \( t = 0 \) one has \( f(0) = \text{int } \cap_{j \geq 1} f_j(0) \subseteq \text{int } \cap_{j \geq 1} f_j(0) = \text{int } f = f^*(0). \) For \( t > 0, \) with regard to monotonicity of \( \{f_j\}_\downarrow, \) we have 
\[
\begin{align*}
\check{f}(t) &= \text{int } \cap_{j \geq 1} f_j(t) = \text{int } \cap_{j \geq 1} (f_j(0))^t = \text{int } \cap_{j \geq 1} (f_j(0))^t \subseteq \text{int } \cap_{j \geq 1} f_j(0)^t = \text{int } f^t = f^*(t). \end{align*}
\]
Hence \( f \leq f^* \) is valid.

Thus, the part (i) of the lemma is proven.

5. For \( t > 0, \) since \( \check{f}^t \) is an open set, one has \( \check{f}^t = \text{int } \check{f}^t. \) Therefore, \( f_*(t) = \text{int } f^t = \text{int } \check{f}^t, \) and (i) implies \( \check{f}(t) = \check{f}^t. \) Hence, \( \check{f}(t) = \check{f}^t = g^t = g(t) \) as \( t > 0. \)

Let \( t = 0. \) Choosing \( MO \ni f_j \searrow f, \) one has \( f(0) = \text{int } \cap_{j \geq 1} f_j(0) \subseteq \text{int } \cap_{j \geq 1} f_j(0) = \text{int } f. \) Hence \( f(0) \subseteq f(t) \subseteq f^t. \) Show that \( f(0) = \text{int } f. \) Indeed, assuming the opposite, one can find \( x \in \text{int } f \) separated from \( f(0) \) with a positive distance. In the mean time, defining \( f^\varepsilon \) by \( f^\varepsilon(t) = (f(0))^{\varepsilon + t}, t \geq 0, \) we get \( f_*(t) = \check{f}^t \subseteq f(t) \subseteq f^\varepsilon(t). \) However, the relation \( \check{f}^t \subseteq f^\varepsilon(t) \) is impossible for small enough \( t \) and \( \varepsilon \) by the choice of \( x. \) Hence, \( f(0) = \text{int } f \) does hold.

The latter implies \( f(0) = \text{int } \check{f} = \text{int } g = g(0). \) Thus, we get \( f(t) = \check{f} = g(t) \) for all \( t > 0 \) and prove (ii). \( \square \)
