Wall properties of peristaltic MHD Nanofluid flow through porous channel

Abstract
In this article, the magnetohydrodynamic (MHD) peristaltic transport of a nanofluid through porous medium is investigated. The effects of the slip conditions together with the wall properties are taken into account. The traveling wave technique is used to obtain the stream function distribution. Also, the homotopy perturbation method (HPM) is utilized to present the other distributions like; temperature and concentration. Finally, several diagrams are plotted to discuss and interpret the effects of various physical parameters of the considered problem. One of the important results of this paper is the behavior of the nanoparticle concentration with different values of Reynolds number, slip parameter, elasticity parameters, thermophoresis parameter, Hartman number and the Brownian motion parameter.

Keywords: nanofluid, Peristalsis, slip conditions, wall properties, porous medium, Homotopy Perturbation Method (HPM), traveling wave solution.

Introduction
In many physiological situations, peristalsis is used by the body to propel or mix the contents of a tube, for example, in a ureter, gastrointestinal tract, the bile duct and the other glandular ducts. One of the important uses of peristaltic pumping is avoiding any internal moving parts such as pistons, in the pumping process. Specifically, in the fluid mechanics, the peristaltic motion is the dynamic interaction of flexible boundary with the fluid. Latham and Shapiro et al. introduced a large amount of information on the peristalsis via theoretical and experimental approaches.

The latest studies in the peristaltic motion can be seen through several articles. Sankad & Patil studied the peristaltic flow of Herschel Bulkley fluid in a non-uniform channel with porous lining. Hayat et al. studied the effects of homogeneous-heterogeneous reactions with convective boundary conditions on peristaltic transport of third order fluid in a channel. Hayat et al. studied the mixed convective peristaltic flow with the effects of Hall current. Kavitha et al. analyzed the peristaltic transport of a Jeffrey fluid. Hayat et al. studied the effects of convective heat and mass conditions in the peristaltic transport.

Due to vast applications of nanofluids with a high rate of heat transfer in engineering and industrial processes, they have gained the attention of researchers. These kinds of fluids occur in liquids which are containing suspensions of nanoparticles. These particles contain carbides, metals, oxides, carbon nanotubes etc. Initially, the term nanofluid presented by Choi as a description of a new class of fluids such as propylene glycol, ethylene glycol, water, oils, silk fibroin, lubricants, and biofluids. Some of the important applications of nanofluids are in heat transfer, pharmaceutical processes, nuclear reactor coolant, space technology and nuclear reactor coolant. Thus, under different assumptions, the works on nanofluids have been progressed by many researchers.

The slip parameter, according to Navier, is the proportionality constant between the difference of the velocities of fluid and of the boundary and the shear stress at that boundary. Fluids exhibiting such behavior are related to many applications such as the polishing of artificial heart valves and internal cavities. Recently effects of slip conditions have been investigated by Aly & Ebaid, and Hayat et al. The flow in a compliant channel has many physiological applications. Such as blood flow in arteries and veins, urine flow in the urethras and air flow in the lungs. Hina studied peristaltic transport of Eyring–Powell fluid with heat/mass transfer, wall properties and slip conditions. There are several investigations to study the effect of the magnetohydrodynaminc (MHD) peristaltic flow of a fluid is of interest in connection with certain problems of the movement of conductive physiological fluids e.g. the blood and blood pump machines. Many researchers have studied MHD peristaltic flow by using different fluids in channel/tubes. Representative attempts in this direction can be mentioned by Refs.

The purpose of the present work is to study the effects of slip conditions, wall properties and porous medium on a magnetohydrodynamic (MHD) peristaltic transport of a nanofluid. The velocity, streamlines, temperature, and nanoparticles concentration distributions were solved through two methods of solutions. The equation of streamlines is solved by using the traveling wave solution method while the equations of the temperature and nanoparticles concentration are solved by using homotopy perturbation method. The results of the streamlines and velocity are compared with the previous results obtained by Srinivas and Gayathri graphically. The structure of the present work is as follows: In section 2 we formulate the problem. In section 3 we present steps of solutions by using two methods of solution (3.1 traveling wave solutions and 3.2 homotopy perturbation method). Our discussion of results was presented in Section 4. Finally, in Section 5, we give concluding remarks for this study.
Formulation of the problem

We consider a two-dimensional flexible porous channel of a uniform thickness.

The walls of the channel are taken as a stretched membrane, on which the traveling sinusoidal wave of moderate amplitude is imposed. The following assumptions are made in this investigation:

a) A magnetic field of strength $B_0$ is considered to be applied parallel to the $y$-axis.

b) The fluid is assumed to be of Newtonian, viscous, incompressible and nanofluid.

c) The motion is assumed to be axisymmetric.

d) We assume that the characteristic properties of this two-dimensional flow depend on the coordinates $(x,y)$, where the flow direction is taken as the $x$-axis and the $y$-axis is vertical.

e) The motion is assumed to be horizontal and the gravity of earth is neglected to facilitate the solution.

As shown in Figure 1 at the steady state $(\eta=\pm L)$, while in the unsteady state $y = \pm \eta (x,t)$ and the channel wall geometry is represented as:

$$\eta (x,t) = d(x) + a \sin \frac{2\pi}{\lambda} (x - c't).$$

(1)

Where $d(x) = d + \mathcal{Q}^{*} x, \mathcal{Q}^{*} \ll 1$.

Under the previous assumptions, the basic equations governing the motion for the problem are:

$$\eta(x,t) = d(x) + a \sin \frac{2\pi}{\lambda} (x - c't).$$

(1)

Figure 1 Geometry of the problem.

The incompressibility conditions yields

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0,$$

(2)

The conservation of momentum gives

$$\rho \left[ \frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} \right] = \frac{\partial P}{\partial x} + \mu \left[ \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right] - \sigma B_0^2 u - \frac{\mu}{K},$$

(3)

And

$$\rho \left[ \frac{\partial v}{\partial t} + u \frac{\partial v}{\partial x} + v \frac{\partial v}{\partial y} \right] = -\frac{\partial P}{\partial y} + \mu \left[ \frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} \right] - \frac{\mu}{K},$$

(4)

The conservation of energy results

$$\rho c_p \left( \frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} \right) + \rho c_v \left( \frac{\partial v}{\partial t} + u \frac{\partial v}{\partial x} + v \frac{\partial v}{\partial y} \right) = \frac{\partial}{\partial x} \left[ \frac{\partial T}{\partial x} \right] + \frac{\partial}{\partial y} \left[ \frac{\partial T}{\partial y} \right],$$

(5)

In the above equations and conditions $u$ and $v$ are the velocity components along the $x$ and $y$ directions respectively. $d(x)$ is the mean half width of the channel, $a$ is the amplitude, $\lambda^*$ is the wavelength, $c^*$...
is the phase speed of the wave, \( Q' \) is the dimensional non-uniformity of channel, \( \rho, \rho_p \) are the density of the fluid and the particle respectively, \( c_r, c_p \) are the volumetric volume expansion of the fluid and the particle respectively, \( p \) is the pressure, \( \mu \) is the coefficient of viscosity of the fluid, \( \sigma \) is the fluid electrical conductivity, \( B_j \) is the applied magnetic field, \( K \) is the permeability of the porous medium, \( k \) is the thermal conductivity of the fluid, \( T \) is the temperature, \( D_s \) is the Brownian diffusion coefficient, \( D_b \) is the thermophoretic diffusion coefficient, the heat transfer and nanoparticle processes are maintained by considering temperatures \( T_p, T \), and nanoparticle phenomena \( C_a, C_i \) to the walls of the channel at \( y = \eta \) and \( -\eta \), respectively, and \( h \) is the dimensional slip parameter.

Introducing a stream function \( \psi \) as \( u = \frac{\partial \psi}{\partial y} \) and \( v = -\frac{\partial \psi}{\partial x} \) and by using the following non-dimensional quantitites:

\[
x' = \frac{x}{\lambda}, \quad y' = \frac{y}{d}, \quad \eta' = \frac{\eta}{d}, \quad K' = \frac{K}{\sigma}, \quad \alpha = \frac{k}{\rho c}, \quad \beta = \frac{h}{d},
\]

\[
\eta' = \frac{\eta}{d}, \quad \rho' = \frac{\rho}{\rho c}, \quad K' = \frac{K}{\sigma}, \quad \alpha = \frac{k}{\rho c}, \quad \beta = \frac{h}{d},
\]

\[
N = \frac{\rho c D_b (C_i - C_a)}{\rho \sigma c}, \quad n^2 = \frac{M}{\rho c}, \quad M^2 = \frac{\beta R}{\rho c}, \quad \rho = \frac{\mu}{\rho c}, \quad \beta = \frac{h}{d},
\]

\[
\psi \left( \frac{\partial \psi}{\partial y} + \frac{\partial \psi}{\partial x} - \frac{\partial \psi}{\partial y} \right) = \delta^3 \left( \frac{\partial \psi}{\partial x} \right) + N_s \frac{\partial^2 \psi}{\partial x^2} + N_i \left( \frac{\partial \psi}{\partial y} \right)^2 + \left( \frac{\partial \psi}{\partial y} \right)^2 + \left( \frac{\partial \psi}{\partial y} \right)^2 + \left( \frac{\partial \psi}{\partial y} \right)^2 + \left( \frac{\partial \psi}{\partial y} \right)^2 + \left( \frac{\partial \psi}{\partial y} \right)^2
\]

\[
R \delta \left( \frac{\partial \psi}{\partial x} + \frac{\partial \psi}{\partial y} - \frac{\partial \psi}{\partial y} \right) = \frac{\partial^2 \psi}{\partial y^2} + \frac{\partial^2 \psi}{\partial x^2} + \frac{\partial^2 \psi}{\partial y^2} - \frac{\partial^2 \psi}{\partial y^2} - \frac{\partial^2 \psi}{\partial y^2} - \frac{\partial^2 \psi}{\partial y^2} = 0
\]

\[
\psi (x, y, t) = 0 \quad \text{at} \quad y = 0, \quad \psi (x, y, t) = 0 \quad \text{at} \quad y = \pm \eta.
\]

Now, in analogy with the definition of the stream function \( \psi \) together with the dimensionless quantities as given in (9), the governing equations of motion given:

\[
R \delta \left( \frac{\partial \psi}{\partial x} + \frac{\partial \psi}{\partial y} - \frac{\partial \psi}{\partial y} \right) = \frac{\partial^2 \psi}{\partial y^2} + \frac{\partial^2 \psi}{\partial x^2} + \frac{\partial^2 \psi}{\partial y^2} - \frac{\partial^2 \psi}{\partial y^2} - \frac{\partial^2 \psi}{\partial y^2} - \frac{\partial^2 \psi}{\partial y^2} = 0
\]

\[
\psi (x, y, t) = 0 \quad \text{at} \quad y = 0, \quad \psi (x, y, t) = 0 \quad \text{at} \quad y = \pm \eta.
\]

Now, the previous system of equations (12-19) will be solved in the next sections.
**Method of solution**

**Traveling wave solutions**

The main advantage of this method is that we can construct exact solutions of higher order nonlinear evolution equations more effectively in comparison with other methods\(^1\). To obtain the solution of the streamlines in Eq. (18) we seek the traveling wave solution in the form

\[
\psi(x,y,t) = f(\xi) \quad \xi = x + y - \lambda t,
\]

Where \(\lambda\) is the wave speed.

Then

\[
\psi_x = \frac{df}{d\xi} f'(\xi), \quad \psi_y = \frac{df}{d\xi} \frac{\partial f}{\partial y} = f'(\xi), \quad \psi_t = \frac{df}{d\xi} \frac{\partial f}{\partial t} = -\lambda f'(\xi),
\]

\[
(20)
\]

Integrating Eq. (24) with respect to \(\xi\) since \(V(\xi) = \frac{d^2f}{d\xi^2}\) then we get

\[
f(\xi) = \frac{M_1}{m_1^2} e^{m_1 \xi} + \frac{M_2}{m_2^2} e^{m_2 \xi} + M_4 \xi + M_3
\]

Substituting from the previous Eq. into Eq. (20) we get

\[
\psi(x,y,t) = \left( -F_3(x,t) \pm \sqrt{F_2(x,t) - 4F_3(x,t)F_5(x,t)} \right) \frac{F_1(x,t) e^{m_1(x+y-\lambda t)} + \frac{1}{m_1^2} e^{m_2(x+y-\lambda t)} + F_7(x,t)(x+y-\lambda t)}{2F_5(x,t)}
\]

As a special case by using the long wavelength approximation and neglecting the wave number along with low-Reynolds number, i.e. \(R = \delta = 0\) one can find that

\[
\psi(x,y,t) = \left( -F_3(x,t) \right) \frac{F_1(x,t) e^{m_1(x+y-\lambda t)} + \frac{1}{m_1^2} e^{m_2(x+y-\lambda t)} + F_7(x,t)(x+y-\lambda t)}{2F_5(x,t)}
\]

By using the boundary conditions (14), (16) and (19) to find the values of \(M_1, M_2, M_3, M_4\), we finally get:

\[
\psi(x,y,t) = \frac{M_1}{m_1^2} e^{m_1(x+y-\lambda t)} + \frac{M_2}{m_2^2} e^{m_2(x+y-\lambda t)} + M_4(x+y-\lambda t) + M_3
\]

\[
(26)
\]

Where, the functions \(M_i(x,t)\) and \(F_i(x,t), i = 1,2,3,\ldots\) are defined in the Appendix.

In order to assess the accuracy of the solution of the streamline and velocity distribution in our problem, the special case (28) was compared with the previous results of Srinivas and Gayathri\(^19\) graphically. There is a good agreement between them, as shown in Figures 2 & 3.

**From Eq. (20), (21) in Eq. (11) we obtain an ordinary differential equation as follows:**

\[
f''(\xi) + Af''(\xi) + Bf''(\xi) = 0
\]

Choose \(V(\xi)\) such that \(V(\xi) = \frac{d^2f}{d\xi^2}\) and substituting into Eq. (22) we get

\[
V''(\xi) + AV''(\xi) + BV(\xi) = 0
\]

which have the solution

\[
V(\xi) = M_1 e^{m_1 \xi} + M_2 e^{m_2 \xi}
\]

Where

\[
\psi(x,y,t) = \frac{M_1}{m_1^2} e^{m_1(x+y-\lambda t)} + \frac{M_2}{m_2^2} e^{m_2(x+y-\lambda t)} + M_4(x+y-\lambda t) + M_3
\]

\[
(24)
\]

\[
(25)
\]

\[
(23)
\]

\[
(22)
\]

\[
(21)
\]

\[
(20)
\]

**Homotopy Perturbation method**

To find the solution of temperature and nanoparticles concentration in Eqs. (12) and (13), we use the homotopy perturbation method. This technique is a combination of the perturbation method and the homotopy method which eliminates the drawbacks of the traditional perturbation methods while keeping all their advantages. On the basis of the homotopy perturbation method\(^23-30\) we can write (12) and (13) as follows:

\[
H(\theta,q) = (1-q) \left[ I(\theta) - I(\theta_0) \right] + q \left[ I(\theta) - R Pr \delta(\theta_1 + \psi_{1\theta} - \psi_{1\theta_1}) + \delta^2 \theta_1^2 + \delta^2 \theta_1^2 + N_1 \theta_1^2 + N_1 \theta_1^2 \right],
\]

\[
(29)
\]

\[
H(\Omega,q) = (1-q) \left[ I(\Omega) - I(\bar{\Omega}_0) \right] + q \left[ I(\Omega) - RSg \delta(\bar{\Omega}_1 + \psi_{1\Omega} - \psi_{1\bar{\Omega}_1}) + \delta^2 \bar{\Omega}_1^2 + \delta^2 \bar{\Omega}_1^2 + \frac{N_1 \bar{\Omega}_1^2}{N_1} + \frac{N_1 \bar{\Omega}_1^2}{N_1} \right],
\]

\[
(30)
\]
Here, $I(\theta)$ and $I(\Omega)$ give the linear operator chosen as $\frac{\partial^2}{\partial y^2}$. The initial approximations $\delta_0$ and $\Omega_0$ can be defined as

$$\delta_0(x,y,t) = \frac{1}{2\eta_0(x,t)}(y + \eta(x,t)) = \Omega_0(x,y,t) \quad (31)$$

Let us define

$$\theta(y,q) = \delta_0 + q\delta_1 + q^2\delta_2 + \ldots \quad (32)$$

$$\Omega(y,q) = \Omega_0 + q\Omega_1 + q^2\Omega_2 + \ldots \quad (33)$$

Incorporating Eqs. (32), (33) into Eqs. (29), (30) (with deriving $y^r$ from Eq. (27) with respect to $x$ and $y$) and then equating like powers of $q$, one observes the system of equations along with the relative boundary conditions. According to the scheme of the HPM, we have the final solutions for temperature and nanoparticles concentration when $q \to 1$ as.

Where, all functions $s_j(x,t)$, $i = 1 \to 46$ and $R_j(x,t)$, $i = 1 \to 48$ are defined in the Appendix. In calculating and plotting the functions we used the Mathematical program.

**Results and discussion**

This section elucidates the behavior of velocity profile, nanoparticle concentration, temperature profile and streamlines configuration on different involved parameters and also it contains a comparison between the present results of the velocity and streamlines and the previous results of Srinivas and Gayathri which is considered as a special case of our work by using the long wavelength approximation and neglecting the wave number along with low-Reynolds number. The results are compared in Table 1 and graphically in Figure 2 and Figure 3. There is an excellent match between the two solutions as shown in the table and figures.

**The velocity profile**

Figure 4 has been plotted to see the impact of the Slip parameter $\beta$ on velocity profile. As the resistance is reduced due to the deviation of fluid in a channel which enhances the velocity profile (Figure 4). It is noted from Figure 5 that the velocity profiles is strictly decreasing for increasing values of the porous parameter. It is illustrated that the presence of porous medium is to enhance increase the resistance to the flow. Which retards the fluid velocity and this associated with a decrease in the momentum boundary layer thickness. Magnetic field applied in a transverse direction acts as a retarding force for the fluid flow and thus the velocity profile decreases for increasing values of Hartman number $M$ as shown in Figure 6.

**Table 1 Comparison between the present results of the velocity $u$ for various values of $\gamma$ and the previous results of Srinivas and Gayathri which is considered as a special case of our work at $R = 0; \delta = 0; M = 3; k = 2; Q = 0.1; E_1 = 2; E_2 = 0.7; E_3 = 0.1; Pr = 0; N_0 = 0; N_1 = 0; \omega = 0.15; \beta = 0.2.$**

**The nanoparticle concentration**

The effect of Hartman number $M$ on nanoparticle concentration is presented in Figure 7. The reduction in the nanoparticle concentration...
Ω is noticed is response to growing values of the Hartman number M. Because the large values of the Hartman number M support the magnetic field strength which appears to be retarding force for the flow.

\]

Figure 8 shows the effect of the slip parameter \( \beta \) on nanoparticle concentration. The results show that nanoparticle concentration reduces in a particular domain with enhancing the Slip parameter \( \beta \). After that domain, the behavior of the nanoparticle concentration \( \Omega \) is different, where it increases with increasing the Slip parameter \( \beta \).

The influence of the permeability parameter \( k \) on the nanoparticle concentration is analyzed in Figure 9. It is clear from this figures that enhance of the permeability parameter \( k \) from 1 to 1000 (which taken as \( k \to \infty \)) leads to an increase in nanoparticle concentration.

\]

We next move to analyze the effects of the Brownian motion parameter \( N_b \) and the thermophoresis parameter \( N_t \) on the nanoparticle concentration through the Figure 10 and Figure 11 respectively. It is demonstrated that by increasing of the thermophoresis parameter \( N_t \), the volume fraction of nanoparticle increases. On the other hand, an opposite trend has been observed as the Brownian motion parameter \( N_b \) varies. This is because, the random motion of nanoparticles getting increased with an increase in Brownian motion parameter, which in turn an enhancement of fluid temperature and reduction of the nanoparticle diffusion.

Figure 12 represents the impact of Reynolds number \( R \) on nanoparticle concentration. It is observed from this figure that the
nanoparticle concentration increases when Reynolds number $R$ is increased.

Figures 13–15 describe the effects of variation for non-dimensional elasticity parameters $E_1$, $E_2$ and $E_3$ on nanoparticle concentration. The results reveal that elasticity of walls $E_1$, $E_2$ and $E_3$ enhance the nanoparticle concentration.

The temperature profile

Figure 16 shows that the larger values of the Hartman number $M$ produce strong magnetic field that takes out the fluid heat to generate current and so magnetic field tends to act like a retarding force which causes reduction in temperature.
Figure 17 shows the effect of the slip parameter $\beta$ on nanoparticle concentration. The results show that decreasing in temperature profile presences in a specific domain with increasing the Slip parameter $\beta$. After that domain, the relationship is reflected with the Slip parameter $\beta$.

The influence of the permeability parameter $k$ on the temperature profile is analyzed in Figure 18. It is clear from this figure that enhances of the permeability parameter $k$ from $5 \times 10^4$ to 1000 in (which taken as $k \rightarrow \infty$) leads to an increase in temperature profiles. This means that when the holes of the porous medium are very large the loss of the temperature from the fluid to the porous medium by conduction reduces and hence the temperature of the fluid increases.

We next move to analyze the effects of the Brownian motion parameter $N_b$ and the thermophoresis parameter $N_t$ on the temperature profile through the Figures 19–20 respectively. It is demonstrated that the temperature of the fluid increased with an increase in the Brownian motion parameter $N_b$ and the thermophoresis parameter $N_t$. This is because, the random motion of nanoparticles getting increased with an increase in Brownian motion parameter, which in turn an enhancement of fluid temperature.

Figure 21 represents the impact of Reynolds number $R$ on temperature profile. It is observed from this figure that the temperature profile increases when Reynolds number $R$ is increased.
Streamlines configuration

The behavior of the trapping with the permeability parameter $k$ is explained in Figure 25. It shows that the volume of the trapped bolus increases with increasing the permeability parameter $k$ and more trapped bolus appears with increasing the permeability parameter $k$.

The effect of slip parameter $\beta$ on the trapping is illustrated in Figure 26. We observe that streamlines closed loops creating a cellular flow pattern in the channel and more trapped bolus appears with increasing slip parameter $\beta$.

Figure 25 (A–B) Plots of Streamline $\psi$ distribution for the effects of $k$ at $R=5; \delta=0.5; M=4; \lambda=0.2; \varepsilon=0.1; Q=0.1; \beta=0.1; E_1=0.6; E_2=0.4; E_3=0.1$

Figure 26 (A–D) Plots of Streamline $\psi$ distribution for the effects of $\beta$ at $R=5; \delta=0.5; M=4; k=0.5; \lambda=0.2; \varepsilon=0.04; Q=0.2; E_1=0.6; E_2=0.4; E_3=0.1$

Figure 27 highlights of the streamline patterns and trapping for different values of the Hartman number $M$. It is observed that the volume of the bolus decreases with increase of the Hartman number $M$ and slowly disappears for the large value of the Hartman number $M$, where the fluid moves as a bulk.
Conclusion

The main results of our study can be epitomized in the following points:

The velocity u is the increasing function of the slip parameter $\beta$ and the non-dimensional elasticity parameters $E_1$, and $E_2$ while it decreases for the Hartman number M, the permeability of the porous medium k and non-dimensional elasticity parameters $E_3$.

The temperature $\theta$ is the increasing function of the non-dimensional elasticity parameters $E_1$, $E_2$, the porous medium k, the Reynolds number R, the Brownian motion parameter $N_b$ and the thermophoresis parameter $N_t$ while it decreases for the slip parameter $\beta$, the Hartman number M, and non-dimensional elasticity parameters $E_3$.

The nanoparticle concentration is the increasing function of the permeability of the porous medium k, the thermophoresis parameter $N_t$, the Reynolds number R and the non-dimensional elasticity parameters $E_1$, $E_2$, $E_3$ while it decreases for the slip parameter $\beta$, the Hartman number M, and the Brownian motion parameter $N_b$.

The value of trapped bolus is increases with increasing of the slip parameter $\beta$ and the permeability of the porous medium k while it decreases with increasing of the Hartman number M.

Finally, the comparison was made between the present results of the velocity and streamlines and the previous results of Srinivas and Gayathri which is considered as a special case of our work and the results were compared graphically and the graphical comparisons showed an excellent compatible between the curves.

Nomenclature

| Symbol | Description |
|--------|-------------|
| a | Amplitude. |
| $B_0$ | Magnetic field. |
| C | Nanoparticle concentration. |
| $C_v$ | Coefficient of viscous damping forces. |
| $c_f$ | Volumetric volume expansion of the fluid. |
| $c_p$ | Volumetric volume expansion of the particle. |
| $C_p$ | Phase speed. |
| d | Mean half width of the channel. |
| $D_B$ | Brownian diffusion coefficient. |
| $D_T$ | Thermophoretic diffusion coefficient. |
| $E_1, E_2, E_3$ | Non-dimensional elasticity parameters. |
| K | Permeability of the porous medium. |
| k | Thermal conductivity of the fluid. |
| M | Hartman number. |
| $\alpha$ | Prandtl number. |
| $\theta$ | Dimensional and non-dimensional non-uniformity of channel respectively. |
| $Q', Q$ | Reynolds number. |
| $S_C$ | Schmidt number. |
| $T$ | Temperature. |
| $t$ | Time. |
| $u,v$ | Components of velocity along x, y directions. |
| $\beta$ | Knudsen number (Slip parameter). |
| $\rho, \rho_p$ | Density of the fluid and the particle respectively. |
| $\varepsilon, \delta$ | Geometric parameters. |
| $\lambda$ | Wave length. |
| $v$ | Wave speed. |
| $\mu$ | Coefficient of viscosity of the fluid. |
| $\nu$ | Kinematic viscosity. |

Table Continued...

| Nomenclature | Definition |
|--------------|------------|
| $m^*$ | Mass per unit area. |
| $N_b$ | Brownian motion parameter. |
| $N_t$ | Thermophoresis parameter. |
| $p$ | Pressure. |
| $P_s$ | Pressure on the outside surface of the wall due to the tension in the muscles. |
| $\theta$ | Dimensionless temperature. |
| $\sigma$ | Fluid electrical conductivity. |
| $\Omega$ | Dimensionless nanoparticle concentration. |
| $\beta$ | Knudsen number (Slip parameter). |
