Supporting Information

**ABSTRACT:** Noncovalent interactions are ubiquitous in biology, taking on roles that include stabilizing the conformation of and assembling biomolecules, and providing an optimal environment for enzymatic catalysis. Here, we describe a noncovalent interaction that engages the sulfur atoms of cysteine residues and disulfide bonds in proteins—their donation of electron density into an antibonding orbital of proximal amide carbonyl groups. This n→π interaction tunes the reactivity of the CXXC motif, which is the critical feature of thioredoxin and other enzymes involved in redox homeostasis. In particular, an n→π interaction lowers the pK_a value of the N-terminal cysteine residue of the motif, which is the nucleophile that initiates catalysis. In addition, the interplay between disulfide n→π interactions and C5 hydrogen bonds leads to hyperstable β-strands. Finally, n→π interactions stabilize vicinal disulfide bonds, which are naturally diverse in function. These previously unappreciated n→π interactions are strong and underlie the ability of cysteine residues and disulfide bonds to engage in the structure and function of proteins.

**INTRODUCTION**

The cysteine residues of proteins have unique attributes. Their sulphydryl groups not only manifest potent nucleophileicity, but also undergo a facile oxidation reaction to generate disulfide bonds. The descendant cystines are active components of catalytic, oxidation-reduction, and signal transduction pathways, and have distinct physicochemical properties.

Approximately 20% of human proteins are predicted to contain a disulfide bond. Although prevalent, the two sulfur atoms of disulfide bonds are not known to engage with other functional groups in proteins. The unique attributes of disulfide bonds and their component sulfur atoms enticed us to consider their electronic structure in detail.

In a disulfide bond, one lone pair of each sulfur atom resides in a nondegenerate s-type orbital (n_s; Figure 1A), and the other resides in a nondegenerate p-type orbital (n_p; Figure 1B). We envisioned that these four lone pairs could interact with nearby carbonyl groups. In particular, donation of lone-pair electron density into the π* orbital of an adjacent carbonyl group could lead to an n→π* interaction (Figure 1C and D). The shape and higher energy of n_p orbitals confers larger contributions relative to those of n_s orbitals. The existence of such an interaction would underlie an aspect of disulfide bonds that is now unappreciated.

Herein, we use computational methods and bioinformatic analyses to provide evidence that n→π* interactions that originate from sulfur play important roles in the structure and function of proteins. The effects arise from the tuning of the thermodynamic stability of the disulfide bonds, thiols, and thiolates of cysteine residues. We find these effects to be especially important in the reactivity of the CXXC motifs in enzymic active sites, interplay with the C5-hydrogen bonds of β-strands, and polarization of electron density in vicinal disulfide bonds.

**RESULTS AND DISCUSSION**

Protein structures are stabilized by a web of interplaying noncovalent interactions. This web overpowers entropy only barely, as the free energy difference between the folded and unfolded states is merely 5–15 kcal/mol. We examined three
aspects of this web from the perspective of $\pi^*-\pi^*$ interactions that originate from sulfur.

**Disulfide $n\rightarrow\pi^*$ Interactions within the CXXC Motif.**
The CXXC motif, in which two cysteine residues are separated by two other residues, is a prevalent feature of enzymes that mediate redox homeostasis. During a catalytic cycle, a disulfide bond is formed and broken between the two cysteine residues of the motif. The sulphydryl group of a typical cysteine residue has a $pK_a$ value of 8.7. In contrast, the N-terminal cysteine residue in a CXXC motif typically has a $pK_a$ value below physiological pH and is thus highly nucleophilic. The origin of this anomalous acidity has been unclear, despite extensive investigation.

CXXC motifs often reside at the N-terminus of an $\alpha$-helix. In that context, the sulfur atom (S) of only the N-terminal cysteine residue is exposed to solvent. Solvent-accessible surface area calculations on the crystal structures of oxidized and reduced states of thioredoxin and thioredoxin-2 show that the C-terminal cysteine is completely inaccessible regardless of redox state (Figure S1 of the Supporting Information, SI). Moreover, $S\gamma'$ of the N-terminal cysteine residue experiences an increase of ~6-fold in solvent-accessible surface area upon reduction of the active-site disulfide bond. Accordingly, we focused our attention on $S\gamma'$, which is the linchpin of the CXXC motif.

We began by performing Natural Bond Orbital (NBO) second-order perturbation theory calculations on 7 different proteins with an oxidized CXXC motif and a known threedimensional structure. The results revealed a chain of $n\rightarrow\pi^*$ interactions that stabilize the oxidized state of the CXXC motif (Figure 2A, Table S1). Foremost in this network is the interaction of $S\gamma'$ and the $C\equiv O$ carbonyl group. Specifically, lone-pair electron density is donated from this sulfur atom into the $\pi^*$ orbital of the carbonyl group, generating a strong $n\rightarrow\pi^*$ interaction in the oxidized, thiol, and thiolate states (Figures 2B–D; Table S2). The chain is propagated by the formation of a $C\equiv O\cdots C\gamma_{i+1}=O_{i+1} n\rightarrow\pi^*$ interaction (Figure 2E; Tables S1 and S2), and then a $C_{\gamma_{i+1}}=O_{i+1}\cdots C_{\gamma_{i+2}}=O_{i+2} n\rightarrow\pi^*$ interaction (Figure 2F; Tables S1 and S2). This chain of $n\rightarrow\pi^*$ interactions was apparent in all 7 proteins examined and appears to be a ubiquitous feature of CXXC motifs.

Next, we examined oxidized CXXC motifs with known crystal structures and reduction potentials. We found that stronger $n\rightarrow\pi^*$ interactions correlate with lower reduction potentials, that is, more stable disulfide bonds (Figure 3). The effect here is not major, given that 100 mV corresponds to 2.3 kcal/mol. Nonetheless, the electron-donation that arises from disulfide $n\rightarrow\pi^*$ interactions is likely to increase the electrophilicity of a disulfide bond and thereby enhance its reactivity in thiol–disulfide interchange reactions.

To understand how the chain of $n\rightarrow\pi^*$ interactions within CXXC motifs might be leveraged to perform biochemical functions, we examined well-characterized thioredoxins in more detail. In a CXXC motif, $S\gamma'$ has three relevant states: disulfide, thiol, and thiolate. Conversion between these states does not induce substantial conformational changes (Figures S1 and S2). The major change incurred upon reduction of the disulfide bond is in the $\chi_1$ dihedral angle (that is, $N\cdots C\equiv O\cdots C\equiv O/S$), which rotates toward the solvent (Figure S2). In the descendant thiol and thiolate, $S\gamma'$ forms a hydrogen bond with water rather than with $S\gamma'/\cdots H$ or another enzymic functional group. Inspection of both of these three states reveals that all are stabilized by a $S\gamma'\cdots C\equiv O n\rightarrow\pi^*$ interaction (Figure 4; Tables S1 and S2).
Moreover, the S···C=O interaction tends to be stronger than the C=O···C=C=C=C=O interaction. A critical step in catalysis by thioredoxin is deprotonation of Sγ to form the nucleophilic thiolate.12a We find that the S···C=O n→π* interaction in the thiolate state is much greater than that in the thiol state (Figure 4). This difference is likely to make a significant contribution to the diminished pKa of the N-terminal cysteine residue in CXXC motifs. The extant explanation for this low thiol pKa value relies on a presumed macrodipole of the α-helix.17 The dipole of an α-helix18 has not been well-replicated in model systems.19 Moreover, slightly downstream to many CXXC motifs is a proline residue, which induces a kink in the α-helix.20 Such a kink would interrupt the projection of the electric field along the helical axis. Notably, calculations of this thiol pKa have yielded values that are much greater than those observed by experiment,14,17,21 consistent with n→π* interactions being absent from the Hamiltonians employed in typical calculations.

**Interplay of Disulfide n→π* Interactions with C5 Hydrogen Bonds.** A C5 hydrogen bond is an intrinsic feature of β-strands, arising from the overlap of an n-type carbonyl lone pair with the σ* orbital of an adjacent amide N–H bond (Figure 5A).22 Because a large fraction of disulfide bonds in β-strands participate in highly stabilizing n→π* interactions, we sought to examine the interplay between a C5 hydrogen bond and a disulfide n→π* interaction (Figure 5B). To do so, we examined a disulfide bond that originates from a β-strand (Figure 5C).

A disulfide n→π* interaction from Sγ into a carbonyl group polarizes the electron density of the carbonyl group toward its oxygen (Figure 5B). The ensuing increase in electron density could result in a stronger C5 hydrogen bond. We performed

Figure 4. Graph showing calculated E_{n→π*} values (in kcal/mol) within the CXXC motifs of Homo sapiens thioredoxin and thioredoxin-2, and Drosophila melanogaster thioredoxin. Data are listed in Table S2.

Figure 5. Interplay between a disulfide n→π* interaction and C5 hydrogen bond in a β-strand. (A) Natural bond orbitals showing a disulfide n→π* interaction. (B) Network of natural bond orbitals in which the n→π* interaction from panel A enhances an n→σ* interaction (that is, a C5 hydrogen bond) within the half-cystine residue. (C) Image of a model disulfide bond. (D) Scan of the dihedral angle ξ (which is defined in the inset of panel E) in the presence of a disulfide n→π* interaction of E_{n→π*} = 1.65 kcal/mol; data are listed in Table S3. (E) Scan of the dihedral angle ξ in the absence of a disulfide n→π* interaction; data are listed in Table S4. The structure in panels A–C is from PDB entry 4gn2 (Table S5) and was used in the calculations of panels D and E.
relaxed scan calculations of the dihedral angle $\xi$ (that is, H$_i$-$\alpha$-$\beta$-$\gamma$-H$_j$). Each step of these calculations was then subjected to NBO calculations to deconvolute the stabilizing interactions.\textsuperscript{23} Specifically, donation of $n_\pi$ electron density leads to $\Delta E_{n\pi\sigma^*} = 0.30$ kcal/mol at the maximum, an increase of 42% over that in the absence of a $n\pi\pi^*$ interaction. Moreover, the maximal $E_{n\pi\sigma^*}$ is achieved at a dihedral angle $\xi$ that is lower by 15$^\circ$. In essence, the disulfide $n\pi\pi^*$ interaction increases the polarization of the acceptor carbonyl group, resulting in an increase in the energy of an associated CS hydrogen bond. This interplay between disulfide bonds and CS hydrogen bonds bears resemblance to systems in which a hydrogen bond to the oxygen of a carbonyl group enhances the ability of that carbonyl group to accept a stabilizing $n\pi\pi^*$ interaction.\textsuperscript{24}

**$n\pi\pi^*$ Interactions of Vicinal Disulfide Bonds.** The function of cysteine residues in the proteome spans a vast chemical landscape. Vicinal disulfide bonds constitute an intriguing subset of this landscape.\textsuperscript{25} These vicinal disulfide bonds, a sulfur atom is proximal to the carbonyl group of the amide that links the two cysteine residues (Figure 6A). This proximity engenders significant S···C=O $n\pi\pi^*$ interactions (Figure 6B).

The eight-membered ring of a vicinal disulfide bond exists in four distinct conformations (Figure 6C–F). Each of these conformations entails an $n\pi\pi^*$ interaction. We find that the strongest $n\pi\pi^*$ interactions arise from trans-up/down conformations (Figures 6C and D), whereas the weakest interactions arise from cis-up conformations (Figures 6E and F).

The strong disulfide $n\pi\pi^*$ interactions in trans-up/down conformations could play a functional role. These conformations often provide a site for ligand binding.\textsuperscript{24,26} Donation of electrons from the $n_\pi$ and $n_\sigma$ orbitals of a disulfide into the carbonyl $\pi^*$ orbital depletes electron density in the disulfide bond, thereby creating an electropositive and hydrophobic surface (Figure S3), especially in the trans-up/down conformations (Figure S3A,B).

**CONCLUSIONS**

The role of $n\pi\pi^*$ interactions in protein structure and function became apparent in the early 2000s.\textsuperscript{26} Our data expose new terrain in this landscape: the mixing of sulfur $n_\pi$ and $n_\sigma$ orbitals with proximal carbonyl groups can provide an exceptionally strong $n\pi\pi^*$ interaction that enhances the stability of host secondary structures. In general, the stabilization of oxidized, thiol, or thiolate states through $n\pi\pi^*$ interactions extends to protein function. In particular, the thermodynamic stability of the CXXC motif, which is the centerpiece of redox homeostasis, is underpinned by $n\pi\pi^*$ interactions. Finally, we note that the enhanced ability of selenium to donate an $n\pi\pi^*$ interaction\textsuperscript{27} suggests that the effects that we observe with cysteine residues could be amplified with selenocysteine.

**EXPERIMENTAL METHODS**

**Calculations.** All quantum mechanical calculations were performed with Gaussian 09, revision E.01\textsuperscript{31} at the M062x/6-311+g(2d,p) level of theory. Energies (i.e., $E_{n\pi\sigma^*}$ and $E_{\pi\sigma\pi^*}$) were calculated by second-order perturbation theory analysis of optimized structures as implemented with NBO 6.0\textsuperscript{62} in Gaussian 09, revision.
Optimized structures were consistent with those from molecular dynamics and QM/MM calculations. One-dimensional scan calculations were performed by increasing the dihedral angle by 1°-steps and allowing the structure to optimize.
