PURIFICATION AND PROPERTIES OF TRANSKETOLASE FROM PIG LIVER

I. AN ATTEMPT TO RESOLVE THE ENZYME INTO APOENZYME AND COFACTORS

(Received January 29, 1979)

Summary Transketolase, sedoheptulose-7-phosphate: D-glyceraldehyde-3-phosphate glycolaldehyde-transferase [EC 2.2.1.1], was extracted from pig liver and purified 96-fold by ammonium sulfate fractionation, followed by column chromatography using DEAE-cellulose and a Sephadex G-200. Transketolase from pig liver was stable at pH 6.0 and above, whereas it was unstable at lower pH values. It could be resolved into apoenzyme and thiamine pyrophosphate in an acidic medium, in contrast to baker’s or brewer’s yeast transketolase which resolved in an alkaline solution. All the activity of pig liver transketolase was lost upon incubation at pH 5.0 for two hours even at 0°C but about 40% of the original activity could be restored by the addition of excess thiamine pyrophosphate and CaCl₂. Restoration of the activity was achieved effectively at pH 7.6–8.0.

Keywords transketolase, pig liver, purification, property, stability, resolution, reconstitution

Transketolase [EC 2.2.1.1] plays an important role in the metabolism of pentose by producing ribose for nucleic acid synthesis and NADPH for the synthesis of fatty acids and steroids. Transketolase purified from baker’s or brewer’s yeast has a molecular weight of 100,000–140,000 (1,2) and dissociates into two identical subunits of a molecular weight of 50,000–70,000 (2,3). It contains thiamine pyrophosphate (TPP) as a coenzyme (4) and coexists with glyceraldehyde-3-phosphate dehydrogenase [EC 1.2.1.12], a functionally related enzyme (2,5). Transketolase from yeasts is known to release TPP and metal ions, such as Mg²⁺, on alkaline treatment and the resolved enzyme can be reconstituted to a holoenzyme by incubation with TPP and a divalent cation (6–8).

1 富田 義, 齊藤慎一, 石川雅章
Transketolase has been purified from rat liver (9), pig liver and human erythrocytes (11) but compared to that from yeasts, transketolase from mammals has not been fully studied and information about its properties in resolution has only been obtained with rat liver. The present study describes an attempt to resolve transketolase from pig liver and presents evidence that the way in which the resolved enzyme associates with cofactors is different from that in the yeast enzyme.

MATERIALS AND METHODS

Chemicals. TPP, glycyglycine and 2-mercaptoethanol were purchased from Tokyo Kasei Kogyo Co., Ltd. and NADH and NAD were from Oriental Yeast Co., Ltd. Glyceraldehyde-3-phosphate (as barium diethylacetal), triose phosphate isomerase [EC 5.3.1.1] and glycerol-3-phosphate dehydrogenase [EC 1.1.99.5] mixture and glyceraldehyde-3-phosphate dehydrogenase [EC 1.2.1.12] were products of Boehringer-Mannheim Corp. Acrylamide, bisacrylamide and N,N,N',N'-tetramethylenehexamidine were obtained from Seikagaku Kogyo Co., Ltd. Amide Black 10B and DEAE-cellulose were purchased from E. Merck and Brown Co., respectively. The Sephadex G-200 and Sephadex G-25 were from Pharmacia Fine Chemicals. A pentose-5-phosphate mixture was prepared from barium ribose-5-phosphate with ribose-5-phosphate isomerase [EC 5.3.1.6] and xylulose-5-phosphate epimerase [EC 5.1.3.1] by the method of Johnson and Gubler (12). Both ribose-5-phosphate isomerase and xylulose-5-phosphate epimerase were prepared from calf spleen according to the method of Ashwell and Hickman (13). All other chemicals were of special grade from commercial sources.

Purification of transketolase. Fresh pig liver was kept at −20°C until used. The frozen pig liver (100 g) was thawed, minced and homogenized in an ice-cold Waring blender for 5 min in 500 ml of 10 mM Tris-HCl buffer (pH 7.6). The homogenate was centrifuged at 4°C with a refrigerated centrifuge (Tominaga, model S-62) for 20 min at 12,000 × g and the resulting supernatant was used for the purification of transketolase. Solid ammonium sulfate was added to the supernatant to obtain 50% saturation and the mixture was centrifuged for 20 min at 12,000 × g. Solid ammonium sulfate was again added to the resulting supernatant to obtain 60% saturation. The precipitate (50–60% ammonium sulfate-saturated fraction) which was obtained by centrifugation at 12,000 × g was dissolved in about 10 ml of 5 mM potassium phosphate buffer (pH 7.6) and dialyzed against two liters of the same buffer at 4°C for 14 hr. The dialyze containing approximately 500 mg of protein was applied to a DEAE-cellulose column (3.5 × 15 cm) equilibrated with 5 mM potassium phosphate buffer (pH 7.6) and eluted by the same phosphate buffer at a flow rate of 60 ml/hr. The eluate was collected in 5 ml fractions with a fraction collector (Toyo, model SF-160K) and fractions 19–27 containing transketolase activity were combined. Solid ammonium sulfate was added to the combined eluate to obtain a fraction of 50–70% ammonium sulfate saturation in the same way as mentioned above. The precipitate was dissolved in a small amount of 5 mM
potassium phosphate buffer (pH 7.6). Five ml of the solution containing about
100 mg of protein was applied to a Sephadex G-200 column (5 × 100 cm)
equilibrated with 5 mM potassium phosphate buffer (pH 7.6). An upward elution
was made with the same phosphate buffer at a flow rate of 48 ml/hr. The eluate was
collected in 3 ml fractions with the fraction collector.

*Acrylamide disc gel electrophoresis.* Acrylamide disc gel electrophoresis was
used routinely to follow the progress of purification. Electrophoresis was performed
according to the technique of Davis (14) with 50 mM Tris–0.38 M glycine buffer (pH
9.5). Bromophenol blue was used as a tracking dye. Electrophoresis was carried out
at a constant current of two mA per tube. The gels were stained with Amide Black
10B (1% in 7% v/v acetic acid) and destained in 7% v/v acetic acid.

* Determination of transketolase activity.* Transketolase activity was determined
spectrophotometrically by coupling the enzyme with triose phosphate isomerase
and glycerol-3-phosphate dehydrogenase (4). To a quartz cuvette with a 1.0 cm light
path were added 0.1 ml of 0.5 M glycylglycine buffer (pH 7.6), 50 µl of 18 mM CaCl₂,
50 µl of 20 mM TPP and appropriate amounts of the enzyme. Distilled water
was added to make up a total volume of 0.8 ml. After the mixture was incubated at 37°C
for 20 min, 50 µl of 2 mM NADH, the triose phosphate isomerase and glycerol-3-
phosphate dehydrogenase mixture (20 µg of protein) and 50 µl of 60 mM pentose-5-
phosphate mixture were added with gentle mixing and an addition of distilled water
made up a total volume of 1.0 ml. A decrease in the absorbancy of NADH at 340 nm
was recorded at 37°C using a Hitachi spectrophotometer (model 139) equipped with
a temperature-controlled cell attachment (model 139-0880). The amount of protein
was determined by the method of Lowry et al. (15), using crystalline bovine serum albumin (The Armour Laboratories) as a standard.

* Determination of the amount of resolved transketolase and holotransketolase.*
Transketolase activity determined in the presence of excess TPP and CaCl₂
represents the total activity of the resolved enzyme and holoenzyme. Activity
without added TPP and CaCl₂ is that of the holoenzyme. The ratio of resolved
enzyme and of holoenzyme to total enzyme will thus be calculated as follows:

\[
\text{Ratio of resolved enzyme} = \frac{A - B}{A} \times 100 \, (\%)
\]

\[
\text{Ratio of holoenzyme} = \frac{B}{A} \times 100 \, (\%)
\]

where \( A \) represents the enzyme activity with TPP and CaCl₂, and \( B \) represents the
enzyme activity without the cofactors.

* Determination of glyceraldehyde-3-phosphate dehydrogenase.* Glyceraldehyde-3-
phosphate dehydrogenase activity was determined by measuring the reduction of
NAD at 25°C. An increase in absorbance at 366 nm was recorded. The standard
assay mixture (16) was as follows: 0.25 mM NAD, an appropriate amount of the
enzyme, 1 mM 2-mercaptoethanol, 4 mM sodium arsenate, 50 mM Tris-HCl buffer (pH 8.6) and 0.2 mM glyceraldehyde-3-phosphate in a final volume of 1.0 ml.

RESULTS

Purification of transketolase from pig liver

Figure 1 shows the elution profile of transketolase on a DEAE-cellulose column. Transketolase activity was found in the fractions from 17 to 30, among which fraction 24 showed the highest specific activity. The transketolase was eluted slower than bulk protein. A concentrate of the combined fractions 19-27 was then applied to a Sephadex G-200 column. Figure 2 shows the elution profile. The proteins were eluted as one major peak (fraction 88) with two other small peaks while the enzyme activity appeared in only one peak (fraction 120). Table 1 shows

The change in the specific activity of the enzyme during purification. The enzyme preparation thus obtained gave two protein bands with Amide Black staining in acrylamide disc gel electrophoresis. One of them coincided with transketolase in its electrophoretic mobility. Another one which migrated faster than transketolase was assumed to be glyceraldehyde-3-phosphate dehydrogenase since the band was stained by nitroblue tetrazolium upon incubation at 30°C, pH 8.6, for 20 min with fructose diphosphate, NAD, phenazine methosulfate, sodium arsenate and aldolase (5). This was further supported by the fact that the Sephadex G-200 preparation (fraction 120) showed NAD-reducing activity at pH 8.6 in the presence of glyceraldehyde-3-phosphate, 2-mercaptoethanol and sodium arsenate (16). Transketolase was fairly stable and about 95% of the enzyme activity remained for three months at −20°C in 50 mM glycyglycine buffer (pH 7.6).

Resolution of transketolase for cofactors

The following three methods, which were employed by RACKER et al. (6),
DATTA and RACKER (7) and OZAWA et al. (8) in the resolution of yeast transketolase, were applied to the resolution of pig liver transketolase. Purified pig liver transketolase (4.8 mg of protein) was dialyzed against 0.12 M KCl solution (pH 7.4) containing 16 mM EDTA for 48 hr (6, method A); dialyzed against 1.6 M ammonium sulfate solution (pH 7.8) for 16 hr (7, method B); or kept in 25 mM glycylglycine buffer (pH 7.6) at 0°C for 48 hr (8, method C) and the activity was assayed in the presence or absence of TPP (0.1 mM) and CaCl₂ (4.5 mM). As shown in Table 2, the enzyme treated by these three methods showed 66.3–88.9% of the holoenzyme activity even in the absence of added TPP and CaCl₂. These methods

Table 3. Resolution of transketolase in acetate buffer (pH 4.5–6.0).

| pH  | Activity (µmol of NADH oxidized/min/mg protein) | Enzyme resolved (%) |
|-----|-----------------------------------------------|---------------------|
|     | with added TPP and CaCl₂ | without added TPP and CaCl₂ |                  |
| 6.0 | 0.186 (100) | 0.146 (78.5) | 21.5 |
| 5.5 | 0.160 (86.0) | 0.111 (59.7) | 30.6 |
| 5.0 | 0.0819 (44.0) | 0.0358 (19.2) | 56.3 |
| 4.5 | 0.0488 (26.2) | 0.0126 (6.8) | 74.2 |

Numbers in parentheses indicate percent of activities based on activity with added TPP and CaCl₂ at pH 6.0.

Fig. 3. Resolution of transketolase in acetate buffer (pH 5.0). Transketolase (108 µg of protein) was added to 0.5 ml of 0.2 M acetate buffer (pH 5.0) and was incubated at 0°C for the periods indicated. After the pH was adjusted to 7.5, each solution was gel filtered through a Sephadex G-25 column equilibrated with 50 mM glycylglycine buffer (pH 7.6). Enzyme activity was determined in the presence and absence of TPP (1 mM) and CaCl₂ (0.9 mM). — —, With added TPP and CaCl₂; — —, without added TPP and CaCl₂.
RESOLUTION OF TRANSKETOLASE

were therefore not suitable for the resolution of transketolase from pig liver. We then tried using an acidic medium to resolve pig liver transketolase for cofactors. One ml of enzyme solution (4.8 mg of protein) was kept at 0°C for 60 min in 1 ml of 0.1 M acetate buffer of different pH values (pH 4.5–6.0) and activities were determined with and without TPP (0.1 mM) and CaCl₂ (4.5 mM) in the standard assay system. As shown in Table 3, the enzyme was stable at pH 6.0 but it became unstable as the pH of the solution decreased. In contrast, the enzyme was resolved sufficiently at lower pH values. Figure 3 shows the resolution and inactivation of pig liver transketolase during incubation at 0°C in acetate buffer (pH 5.0). Good resolution was achieved after 60 min incubation, when the loss of enzyme activity became almost constant and the resolution proceeded progressively.

Reconstitution of holoenzyme from resolved enzyme and cofactors

The activity of transketolase was measured by incubating the resolved enzyme with various amounts of TPP (10 nM–5 μM) and 4.5 mM CaCl₂ in 0.5 M glycylglycine buffer (pH 7.6) at 37°C for 20 min. As shown in Fig. 4, the activity increased sigmoidally with increasing concentrations of TPP. The formation of holoenzyme was dependent on the pH value of the incubation medium. After the resolved enzyme was incubated with excess TPP (0.1 mM) and CaCl₂ (0.9 mM) in either 40 mM acetate buffer (pH 6.0–6.8) or 40 mM glycylglycine buffer (pH 7.0–8.0) at 37°C for 5 min, the excess cofactors were removed by gel filtration with a Sephadex G-25 equilibrated with the same buffer used for incubating the resolved enzyme. Enzyme activity was determined in the presence or absence of excess TPP and CaCl₂. The results are shown in Fig. 5. The reconstitution of the holoenzyme was incomplete at

Fig. 4. The activity of transketolase as a function of TPP concentration. In a total volume of 1.0 ml, 0.5 M glycylglycine buffer (pH 7.6), resolved transketolase (760 μg), TPP at various concentrations as indicated and 4.5 mM CaCl₂ were incubated at 37°C for 20 min. Enzyme activity was measured as mentioned in the experimental section.
Fig. 5. Effect of the pH on reconstitution of resolved transketolase and cofactors. Resolved transketolase (3.3 mg of protein) was incubated in 0.4 ml of 50 mM acetate buffer (pH 6.0, 6.4, 6.8) or 50 mM glycylglycine buffer (pH 7.0, 7.6, 8.0) with 0.05 ml of 1 mM TPP and 9 mM CaCl₂ at 37°C for 5 min. It was then gel filtered through a Sephadex G-25 column (1 x 30 cm) equilibrated with the same buffer used for incubation of the sample. Enzyme activity was determined in the presence or absence of TPP (1 mM) and CaCl₂ (0.9 mM).

pH 6.0 and 6.4; the enzyme showed only 31 and 40% of the full activity. But the reconstitution was almost complete at pH 7.6 or above.

DISCUSSION

Transketolase from animal tissues is fairly unstable compared to that from yeast and a marked inactivation takes place as the process of purification becomes longer. The present study was conducted to purify transketolase from pig liver as rapidly as possible and to resolve the holoenzyme into apoenzyme and cofactors. As shown in Table 1, transketolase was purified 96-fold in a four-step purification process: extraction, ammonium sulfate fractionation, DEAE-cellulose column chromatography and Sephadex G-200 gel filtration. Transketolase preparations thus obtained showed a specific activity of 0.2 unit/mg of protein and contained glyceraldehyde-3-phosphate dehydrogenase. This enzyme is known to accompany transketolase from yeasts and human erythrocytes. Their separation has not been successful without a marked inactivation in the case of erythrocyte transketolase.

HORECKER et al. (9) reported that the enzyme from rat liver could be resolved by treatment with 0.076 N H₂SO₄. SIMPSON (10), however, reported that application of HORECKER's method to a preparation of transketolase from pig liver was unsuccessful. HEINRICH and WISS (11) also reported that it was difficult to resolve transketolase from human erythrocytes with 0.076 N H₂SO₄.

Transketolase from pig liver was fairly stable at pH 6.0 and above, and full
activity could be restored with the addition of excess cofactors. The transketolase was, however, unstable in a more acidic medium and inactivated by releasing TPP and metal ion, resulting in the formation of resolved enzyme which was further irreversibly inactivated. The rate of inactivation became greater as the pH decreased and thus transketolase, treated at pH 5.5 and 4.5, showed a 14.0 and 73.8% loss of activity, respectively, when assayed with excess TPP and CaCl₂ at pH 6.0. It must be noted, however, that the ratio of activity with and without cofactors increased as the pH decreased and the resolution of the enzyme became larger upon longer incubation (see Fig. 3). Transketolase from pig liver is thus quite different from that from yeast enzyme as the latter can be resolved only at pH 7.0 and above (17, 18).

The difference between transketolase from pig liver and that from yeasts was also observed in the reconstitution experiments. Resolved transketolase from pig liver could be reconstituted at neutral pH and above but not in an acidic medium, while that from yeasts were reconstituted in weakly acidic media (pH 6.0–5.0) but not in alkaline media (pH 7.0–9.0) (18, 19). The binding mode of TPP and metal ion on apoenzymes from the two sources are thus apparently different.
