Abstract

We study quantitative asymptotics of planar random walks that are spatially non-homogeneous but whose mean drifts have some regularity. Specifically, we study the first exit time $\tau_\alpha$ from a wedge with apex at the origin and interior half-angle $\alpha$ by a non-homogeneous random walk on $\mathbb{Z}^2$ with mean drift at $x$ of magnitude $O(\|x\|^{-1})$ as $\|x\| \to \infty$. This is the critical regime for the asymptotic behaviour: under mild conditions, a previous result of the authors stated that $\tau_\alpha < \infty$ a.s. for any $\alpha$. Here we study the more difficult problem of the existence and non-existence of moments $E[\tau_\alpha^s]$, $s > 0$. Assuming a uniform bound on the walk’s increments, we show that for $\alpha < \pi/2$ there exists $s_0 \in (0, \infty)$ such that $E[\tau_\alpha^s]$ is finite for $s < s_0$ but infinite for $s > s_0$; under specific assumptions on the drift field we show that we can attain $E[\tau_\alpha^s] = \infty$ for any $s > 1/2$. We show that there is a phase transition between drifts of magnitude $O(\|x\|^{-1})$ (the critical regime) and $o(\|x\|^{-1})$ (the subcritical regime). In the subcritical regime we obtain a non-homogeneous random walk analogue of a theorem for Brownian motion due to Spitzer, under considerably weaker conditions than those previously given (including work by Varopoulos) that assumed zero drift.

Key words and phrases: Angular asymptotics; non-homogeneous random walk; asymptotically zero perturbation; passage-time moments; exit from cones; Lyapunov functions.

1 Introduction

By a random walk on $\mathbb{R}^d$ ($d \geq 2$) we mean a discrete-time time-homogeneous Markov process on $\mathbb{R}^d$. If such a random walk is spatially homogeneous, its position can be expressed as a sum of i.i.d. random vectors; such homogeneous random walks are classical and have
been extensively studied, particularly when the state-space is \( \mathbb{Z}^d \): see for example [15, 22].

The most subtle case is that of zero drift, i.e., when the increments have mean zero.

Spatial homogeneity, while simplifying the mathematical analysis, is not always realistic for applications. As soon as the spatial homogeneity assumption is relaxed to study non-homogeneous random walks, the situation becomes much more complicated. Even in the zero-drift case, a non-homogeneous random walk can behave completely differently to a zero-drift homogeneous random walk, and can be transient in two dimensions, for instance. This potentially wild behaviour means that techniques from the study of homogeneous random walks are difficult to apply.

In this paper we continue the study, begun in [16], of angular asymptotics, i.e., exit-from-cones problems, for non-homogeneous random walks for which the magnitude of the mean drift at \( x \in \mathbb{R}^d \) tends to 0 as \( \|x\| \to \infty \). This asymptotically zero drift regime is the natural model in which to probe phase transitions in asymptotic behaviour, analogously to the one-dimensional problems considered by Lamperti [12, 13].

Before formally defining our model and stating our theorems, we informally describe existing results, the results in the present paper, and their significance. In [16], we studied the exit time \( \tau_\alpha \) from a cone with interior half-angle \( \alpha \) for a non-homogeneous random walk on \( \mathbb{Z}^d \). For a zero-drift, homogeneous random walk, it is a classical result that \( \tau_\alpha < \infty \) a.s. for any \( \alpha \), and tail asymptotics for \( \tau_\alpha \) are known [23, 24]. Our primary interest is how the situation changes when the walk is allowed to be non-homogeneous, and in particular, to quantify the effect of introducing an asymptotically small mean drift.

We use \( \mu(x) \) to denote the one-step mean drift vector of the walk at \( x \). Unlike other asymptotic properties of the walk, it was shown in [16, Theorem 2.1] that the a.s.-finiteness of \( \tau_\alpha \) remains valid for non-homogeneous random walks provided \( \|\mu(x)\| = O(\|x\|^{-1}) \) as \( \|x\| \to \infty \), under mild assumptions. In contrast, such a random walk can be positive-recurrent, null-recurrent, or transient: see e.g. results of Lamperti [12, 13]. On the other hand, it was shown in [16, Theorem 2.2] that \( \mu(x) \) of magnitude \( \|x\|^{-\beta} \), \( \beta \in (0, 1) \), can ensure that the walk eventually remains in an arbitrarily narrow cone: under mild conditions the walk is transient with a limiting direction and a super-diffusive rate of escape [19, §3.2]. These facts motivate the following terminology. If \( \|\mu(x)\| \) is of magnitude (i) \( o(\|x\|^{-1}) \); (ii) \( \|x\|^{-1} \); (iii) \( \|x\|^{-\beta} \), \( \beta \in (0, 1) \) we say that the walk is in the (i) subcritical; (ii) critical; (iii) supercritical regime, respectively.

The present paper is concerned with the critical and subcritical regimes, for which we know from [16] that \( \tau_\alpha < \infty \) a.s.; now we want finer information about the random variable \( \tau_\alpha \): in particular, its tails (which moments exist). Thus the present paper is concerned with qualitative information to complement the qualitative results of [16].

There are two main themes of the present paper. First, we show that provided that \( \|\mu(x)\| = O(\|x\|^{-1}) \), \( \tau_\alpha \) has a polynomial tail, i.e., \( \mathbb{E}[\tau_\alpha^s] \) is finite for \( s > 0 \) small enough but infinite for \( s > 0 \) large enough. Second, we demonstrate a phase transition in the tail of \( \tau_\alpha \) between the critical and subcritical regimes. Our main result on the subcritical regime is that not only does the property \( \tau_\alpha < \infty \) a.s. carry across from the homogeneous zero-drift case, but also that finer information on the moments of \( \tau_\alpha \) transfers, under mild additional conditions. On the other hand, we give results that show that the critical case is genuinely different: there is a quantitative phase transition.

Studying the moments of \( \tau_\alpha \) is much more difficult than determining whether \( \tau_\alpha \) is a.s. finite, so in the present paper we have to impose stronger conditions on the random walk than those in [16]. In particular, we impose a uniform bound on the increments of the walk (as opposed to the 2nd moment bound used in [16]) and we restrict to two
dimensions (in [16] the walk lived on \( \mathbb{Z}^d, d \geq 2 \)). As well as reducing technicalities, using \( \mathbb{Z}^2 \) enables us to present our results as clearly as possible since even the Brownian motion case becomes quite involved in \( d > 2 \) [2, 4]. We do not, however, need to assume any symmetry for the increments (as required, for example, in [14, 20]).

In the homogeneous zero-drift setting, for the analogous continuous problem of planar Brownian motion in a wedge, a classical result of Spitzer [21, Theorem 2] says that \( \mathbb{E}[\tau_p] < \infty \) if and only if \( p < \pi/(4\alpha) \). A deep study of passage-time moments for Brownian motion in \( \mathbb{R}^d \) was carried out by Burkholder [2]. The random walk problem has received less attention, even in the homogeneous zero-drift case. Varopoulos [23, 24] studied tails of passage-times for zero-drift random walks satisfying various conditions including bounded increments and isotropic covariance; some results of [23, 24] allow the walk to be spatially inhomogeneous (at the expense of additional technical conditions, stronger than ours), but all require zero drift. From [23, 24] one can obtain a version of Spitzer’s theorem for Brownian motion in the case of zero-drift random walks satisfying appropriate regularity conditions. Exit times from cones for homogeneous random walks are also studied in [8]; somewhat related results are in [9]. Other relevant results specialize to the quarter-lattice \( \mathbb{Z}^+ \times \mathbb{Z}^+ \) [3, 11] or the hitting-time of a half-line [7, 15]. Certain non-homogeneous random walks with linear rate of escape were studied in [6].

We show that Spitzer’s theorem for Brownian motion essentially extends, under moderate regularity conditions, to non-homogeneous random walks with mean drifts that vanish as \( o(||x||^{-1}) \). This considerably broadens the spectrum of walks for which a Spitzer-type result is known; previous work considered only the zero-drift case [23, 24].

In the next section we formally define our model and state our main results.

## 2 Results and discussion

In the plane \( \mathbb{R}^2 \), \( e_1, e_2 \) denote orthonormal basis vectors, \( 0 = (0,0) \) is the origin, and \( || \cdot || \) the Euclidean norm. For \( x \in \mathbb{R}^2 \), write \( x = (x_1, x_2) \) where \( x_i = x \cdot e_i \). Our random walk \( \Xi = (\xi_t)_{t \in \mathbb{Z}^+} \) is a Markov process with state-space an unbounded subset \( \mathcal{S} \) of \( \mathbb{Z}^2 \).

To ensure that the walk cannot become trapped in lower-dimensional subspaces or finite sets, we assume the following weak isotropy condition:

\[ \text{(A1) There exist } \kappa > 0, k \in \mathbb{N} \text{ and } n_0 \in \mathbb{N} \text{ such that} \]
\[ \min_{x \in \mathcal{S}; y \in \{\pm ke_1, \pm ke_2\}} \mathbb{P}[\xi_{t+n_0} - \xi_t = y \mid \xi_t = x] \geq \kappa, \quad (t \in \mathbb{Z}^+). \]

Note that (A1) is weaker than the ‘uniform ellipticity’ often assumed in the non-homogeneous random walk or random walk in random environment literature (see e.g. [14, 20]); for a discussion of the strength and implications of (A1), see [16].

Let \( \theta_t := \xi_{t+1} - \xi_t \) denote the jump of \( \Xi \) at time \( t \in \mathbb{Z}^+ \). Since \( \Xi \) is time-homogeneous and Markovian, the distribution of the random vector \( \theta_t \) depends only upon the location \( \xi_t \in \mathcal{S} \) at time \( t \). In other words, there exists a \( \mathbb{Z}^2 \)-valued random field \( \theta = (\theta(x))_{x \in \mathcal{S}} \) such that for all \( t \in \mathbb{Z}^+ \), \( \mathcal{L}(\xi_{t+1} - \xi_t \mid \xi_t) = \mathcal{L}(\theta_t \mid \xi_t) = \mathcal{L}(\theta(\xi_t)) \). The law of \( \theta \) is the jump distribution of \( \Xi \). We write \( \theta(x) \) in components as \( (\theta_1(x), \theta_2(x)) \).

Our second regularity condition is an assumption of uniformly bounded jumps:

\[ \text{(A2) There exists } b \in (0, \infty) \text{ such that } \mathbb{P}[||\theta(x)|| > b] = 0 \text{ for all } x \in \mathcal{S}. \]
It is likely that (A2) could be replaced by a moment assumption with some technical work, but (A2) is frequently adopted in the literature: see e.g. [14, 20, 23]. Under (A2), the moments of \( \theta_t \) are well-defined. Denote the one-step mean drift vector

\[
\mu(x) := \mathbb{E}[\theta_t | \xi_t = x] = \mathbb{E}[\theta(x)],
\]

for \( x \in S \), and write \( \mu(x) = (\mu_1(x), \mu_2(x)) \) in components. We are interested in the case of asymptotically zero mean drift, i.e., \( \lim_{\|x\| \to \infty} \|\mu(x)\| = 0 \).

For \( \alpha \in (0, \pi) \), we denote by \( \mathcal{W}(\alpha) \) the (open) wedge with apex at \( 0 \), principal axis in the \( e_1 \) direction, and interior half-angle \( \alpha \):

\[
\mathcal{W}(\alpha) := \{ x \in \mathbb{R}^d : e_1 \cdot x > \|x\| \cos \alpha \}.
\]

Thus \( \mathcal{W}(\pi/4) = \{(x_1, x_2) : x_1 > 0, |x_2| < x_1 \} \) is a half-plane. The case \( \alpha = \pi \) we will treat slightly differently: for \( s \geq 0 \), define \( \mathcal{H}_s := \{(x_1, x_2) : x_1 \leq 0, |x_2| \leq s \} \); for \( s > 0 \) this is a thickened half-line. Then with \( b > 0 \) the jump bound in (A2), set \( \mathcal{W}(\alpha) := \mathbb{R}^2 \setminus \mathcal{H}_b \). (For convenience, we often call \( \mathcal{W}(\alpha) \) a ‘wedge’ also.) It will also be convenient to set \( \mathcal{W}(\alpha) := \mathbb{R}^2 \) for any \( \alpha > \pi \).

Our primary concern is the random walk’s first exit time from the wedge \( \mathcal{W}(\alpha) \). With the usual convention that \( \min 0 := \infty \), define

\[
\tau_\alpha := \min \{ t \in \mathbb{Z}^+ : \xi_t \notin \mathcal{W}(\alpha) \}.
\]

The following fundamental result shows that \( \tau_\alpha \) is a.s. finite if the mean drift decays fast enough. Theorem 2.1 is essentially contained in [16]: indeed, [16, Theorem 2.1] gives such a result under conditions much weaker than (A2) and in general dimensions \( d \geq 2 \), but excluding the case \( \alpha = \pi \). We will give a self-contained proof of Theorem 2.1 that requires minimal extra work on top of that to obtain our main results.

**Theorem 2.1.** Suppose that (A1) and (A2) hold, and that for \( x \in S \) as \( \|x\| \to \infty \),

\[
\|\mu(x)\| = O(\|x\|^{-1}).
\]

Then for any \( \alpha \in (0, \pi] \) and any \( x \in \mathcal{W}(\alpha) \), \( \mathbb{P}[\tau_\alpha < \infty | \xi_0 = x] = 1 \).

Our first substantially new result, Theorem 2.2, shows that even for this non-homogeneous walk, the tails of \( \tau_\alpha, \alpha < \pi/2 \), are essentially polynomial; the ‘heaviness’ of the tail depends on the details of the walk: compare Theorems 2.3 and 2.4 below.

**Theorem 2.2.** Suppose that (A1) and (A2) hold, \( \alpha \in (0, \pi/2) \), and that for \( x \in S \), (2.2) holds as \( \|x\| \to \infty \). Then there exist \( s_0, A \in (0, \infty) \) such that:

(i) if \( s < s_0 \), then \( \mathbb{E}[\tau_\alpha^s | \xi_0 = x] < \infty \) for any \( x \in \mathcal{W}(\alpha) \);

(ii) if \( s > s_0 \), then \( \mathbb{E}[\tau_\alpha^s | \xi_0 = x] = \infty \) for any \( x \in \mathcal{W}(\alpha) \) with \( \|x\| \geq A \).

**Remarks.** (a) It is an open problem to show that Theorem 2.2 holds for \( \alpha \geq \pi/2 \).

(b) Theorem 2.2(ii) cannot be strengthened to all \( x \in \mathcal{W}(\alpha) \) without stronger regularity conditions on the walk \( \Xi \). Indeed, under (A1), it may be that for \( \xi_t \) close to the boundary of \( \mathcal{W}(\alpha) \), \( \xi_{t+1} \) is outside \( \mathcal{W}(\alpha) \) with probability 1; however, this cannot occur for \( \|\xi_t\| \) large enough by our asymptotically zero drift assumption: see Lemma 4.9 below. The same remark applies to our other non-existence of moments results that follow.
Walks satisfying Theorem 2.2 can have radically different characteristics. For small enough wedges a zero-drift walk has \(\mathbb{E}[\tau_\alpha] < \infty\) (see Theorem 2.4 below); on the other hand, the next result implies that for any \(\alpha \in (0, \pi/2)\), for a suitably strong \(O(\|x\|^{-1})\) drift field, \(\mathbb{E}[\tau_\alpha] = \infty\). In fact, Theorem 2.3 says that for any \(\varepsilon > 0\), there exist walks satisfying the conditions of Theorem 2.2 for which \(\mathbb{E}[\tau_\alpha^{(1/2)+\varepsilon}] = \infty\).

We take the random walk to have dominant drift in the principal direction. Specifically, we assume that there exists \(c > 0\) for which

\[
\liminf_{\|x\| \to \infty} (\|x\| \mu_1(x)) \geq c, \quad \lim_{\|x\| \to \infty} (\|x\| \mu_2(x)) = 0. \tag{2.3}
\]

**Theorem 2.3.** Suppose that (A1) and (A2) hold, and \(\alpha \in (0, \pi/2)\). Then for any \(s > 0\), there exist \(c_0, A \in (0, \infty)\) such that if (2.3) holds for any \(c > c_0\), then for all \(x \in \mathcal{W}(\alpha)\) with \(\|x\| \geq A\), \(\mathbb{E}[\tau_\alpha^{(1/2)+s} | \xi_0 = x] = \infty\).

Our final result, Theorem 2.4, gives sharp tail asymptotics for \(\tau_\alpha\) in the subcritical regime. To obtain such a sharp result, we need to assume additional regularity for \(\Xi\): specifically, we need to control the covariance structure of its increments. Denote the covariance matrices \(M = (M_{ij})_{i,j \in \{1,2\}}\) of \(\theta\) by

\[
M(x) := \mathbb{E}[\theta_i^\top \theta_t | \xi_t = x] = \mathbb{E}[\theta(x) \theta(x)],
\]

for \(x \in \mathcal{S}\), where \(\theta_t\) is viewed as a row-vector. When (A1) holds, \(\mathbb{P}[\xi_{t+1} \neq x | \xi_t = x]\) is uniformly positive [16, p. 354] so that \(M_{11}(x) + M_{22}(x) > 0\) uniformly in \(x\).

Theorem 2.4 shows that the critical exponent for the moment problem depends only on \(\alpha\) and is the same in this random walk setting as in the Brownian motion case, where the result is due to Spitzer [21, Theorem 2]. In particular, Theorem 2.4 includes the case of a homogeneous random walk with zero drift, where the result follows from [23, Theorem 4] (see also [24]). We write \(o(1)\) for a \(2 \times 2\) matrix each of whose entries is \(o(1)\).

**Theorem 2.4.** Suppose that (A1) and (A2) hold, and there exists \(\sigma^2 \in (0, \infty)\) such that

\[
\|\mu(x)\| = o(\|x\|^{-1}), \quad \text{and } M(x) = \sigma^2 I + o(1), \tag{2.4}
\]
as \(\|x\| \to \infty\). Suppose that \(\alpha \in (0, \pi]\).

(i) If \(s \in [0, \pi/(4\alpha))\) and \(x \in \mathcal{W}(\alpha)\), \(\mathbb{E}[\tau_\alpha^s | \xi_0 = x] < \infty\).

(ii) If \(s > \pi/(4\alpha)\) and \(x \in \mathcal{W}(\alpha)\) with \(\|x\|\) sufficiently large, \(\mathbb{E}[\tau_\alpha^s | \xi_0 = x] = \infty\).

Certain cases of Theorem 2.4 extend results of Klein Haneveld and Pittenger [11] and Lawler [15] for homogeneous zero-drift random walks to non-homogeneous random walks with small drifts. First, for hitting a half-line (\(\alpha = \pi\)), Theorem 2.4 implies that 1/4-moments are critical, a result obtained in the homogeneous zero-drift case by Lawler (see (2.35) in [15], also [7]). Second, for a quadrant (\(\alpha = \pi/4\)), Theorem 2.4(ii) implies that \(\mathbb{E}[\tau_\alpha^s] = \infty\) for \(s > 1\), a result contained in [11, Theorem 1.1] for a homogeneous zero-drift walk with certain regularity conditions (see also [3, Theorem 1.1]).

The outline of the rest of the paper is as follows. Section 3 collects some preparatory results. Section 4 is devoted to the critical case and the proofs of Theorems 2.1, 2.2 and 2.3, while Section 5 is devoted to the subcritical case and the proof of Theorem 2.4.
3 Preliminaries

In this section we introduce and analyze Lyapunov functions that we will use in the subcritical case. For \( \mathbf{x} = (x_1, x_2) \in \mathbb{R}^2 \) we use polar coordinates \((r, \varphi)\) relative to the ray \( \Gamma_0 \) in the \( e_1 \) direction starting at \( 0 \). Thus if \( r = \| \mathbf{x} \| \) and \( \varphi \in (-\pi, \pi] \) is the angle, measuring anticlockwise, of the ray through \( 0 \) and \( \mathbf{x} = (x_1, x_2) \) from the ray \( \Gamma_0 \), we have \( x_1 = r \cos \varphi \) and \( x_2 = r \sin \varphi \). We occasionally write \( \varphi = \varphi(\mathbf{x}) \) for clarity. Let \( \mathbf{e}_r(\varphi) = e_1 \cos \varphi + e_2 \sin \varphi \), the radial unit vector, and \( \mathbf{e}_\perp(\varphi) = -e_1 \sin \varphi + e_2 \cos \varphi \), the transverse unit vector. Then in polar coordinates, \( \mathcal{W}(\alpha) = \{ x \in \mathbb{R}^2 : r > 0, -\alpha < \varphi < \alpha \} \).

Let \( B_r(\mathbf{x}) \) denote the closed Euclidean ball of radius \( r \) centred at \( \mathbf{x} \in \mathbb{R}^2 \). For \( \alpha \in (0, \pi] \) and \( s \geq 0 \) define \( \mathcal{W}_s(\alpha) := \mathcal{W}(\alpha) \setminus B_s(0) = \{ x \in \mathcal{W}(\alpha) : \| x \| > s \} \). For \( A \geq 0 \), set

\[
\tau_{\alpha,A} := \min \{ t \in \mathbb{Z}^+ : \xi_t \notin \mathcal{W}_A(\alpha) \}.
\]

Then \( \tau_{\alpha,A} \geq \tau_{\alpha,B} \) for \( B \geq A \), and \( \tau_{\alpha,0} = \tau_\alpha \) with the notation of (2.1).

We use multi-index notation for partial derivatives on \( \mathbb{R}^2 \). For \( \sigma = (\sigma_1, \sigma_2) \in \mathbb{Z}^+ \times \mathbb{Z}^+ \), \( D_\sigma = D_{\sigma_1}D_{\sigma_2} \) will denote \( D_1^{\sigma_1}D_2^{\sigma_2} \) where \( D_j^k \) for \( k \in \mathbb{N} \) is \( k \)-fold differentiation with respect to \( x_j \), and \( D_j^0 \) is the identity operator. We also use the notation \( |\sigma| := \sigma_1 + \sigma_2 \) and \( \mathbf{x}^\sigma := x_1^{\sigma_1}x_2^{\sigma_2} \). For \( w > 0 \), define the function \( f_w : \mathbb{R}^2 \to \mathbb{R} \) by

\[
f_w(\mathbf{x}) := f_w(r, \varphi) := r^w \cos(w\varphi).
\]

Differentiation, using the appropriate form of the chain rule, shows that for any \( w > 0 \),

\[
D_1f_w(r, \varphi) = wr^{w-1} \cos((w - 1)\varphi); \quad D_2f_w(r, \varphi) = -wr^{w-1} \sin((w - 1)\varphi),
\]

and

\[
D_1D_2f_w(r, \varphi) = D_2D_1f_w(r, \varphi) = w(w - 1)r^{w-2} \sin((w - 2)\varphi).
\]

Moreover, \( f_w \) is harmonic on \( \mathbb{R}^2 \), since

\[
D_1^2f_w(r, \varphi) = w(w - 1)r^{w-2} \cos((w - 2)\varphi) = -D_2^2f_w(r, \varphi).
\]

For \( w > 1/2 \), \( f_w \) is positive in the interior of the wedge \( \mathcal{W}(\pi/(2w)) \), and 0 on the boundary \( \partial \mathcal{W}(\pi/(2w)) \); \( f_{1/2} \) is positive on \( \mathbb{R}^2 \setminus \mathcal{H}_0 \) and zero on the half-line \( \mathcal{H}_0 \). For \( w \in (0, 1/2) \), \( f_w \) is positive throughout \( \mathbb{R}^2 \). As an example, the harmonic function

\[
f_2(\mathbf{x}) = r^2 \cos(2\varphi) = x_1^2 - x_2^2
\]

is positive on the quadrant \( \mathcal{W}(\pi/4) \) and zero on \( \partial \mathcal{W}(\pi/4) \).

It follows by repeated applications of the chain rule that \( f_w \) and all of its derivatives \( D_\sigma f_w \) are of the form \( r^k u(\varphi) \) where \( u \) is bounded, and hence for any \( \sigma \) with \( |\sigma| = j \) there exists a constant \( C \in (0, \infty) \) such that for all \( \mathbf{x} \in \mathbb{R}^2 \),

\[
-Cr^{w-j} < D_\sigma f_w(\mathbf{x}) < Cr^{w-j}.
\]

The next result gives expressions for the first three moments of the jumps of \( f_w(\xi_t) \).

**Lemma 3.1.** Suppose that (A2) holds. Then with \( f_w \), defined at (3.2), for \( w > 0 \), there exists \( C \in (0, \infty) \) such that for any \( \mathbf{x} \in \mathcal{S} \),

\[
P[|f_w(\xi_{t+1}) - f_w(\xi_t)| \leq C(1 + \| \mathbf{x} \|)^{w-1} \ | \xi_t = \mathbf{x}] = 1.
\]
Also, for any $x \in S$ as $r = ||x|| \to \infty$, we have the following asymptotic expansions:

\[ E[f_w(\xi_{t+1}) - f_w(\xi_t) \mid \xi_t = x] = wr^{w-1} (\mu_1(x) \cos((w-1)\varphi) - \mu_2(x) \sin((w-1)\varphi)) + \frac{1}{2} (M_{11}(x) - M_{22}(x)) w(w-1)r^{w-2} \cos((w-2)\varphi) + M_{12}(x) w(w-1)r^{w-2} \sin((w-2)\varphi) + O(r^{w-3}); \]

(3.9)

\[ E[(f_w(\xi_{t+1}) - f_w(\xi_t))^2 \mid \xi_t = x] = w^2 r^{2w-2} (M_{11}(x) \cos^2((w-1)\varphi) + M_{22}(x) \sin^2((w-1)\varphi)) - M_{12}(x) w^2 r^{2w-2} \sin(2(w-1)\varphi) + O(r^{2w-3}); \]

(3.10)

\[ E[(f_w(\xi_{t+1}) - f_w(\xi_t))^3 \mid \xi_t = x] = O(r^{3w-3}). \]

(3.11)

Proof. Since $f_w$ is smooth, Taylor’s theorem with Cartesian coordinates and Lagrange remainder applied in a disk of radius $b$ at any $x \in \mathbb{R}^2$ implies that $f_w(x + y) = f_w(x) + \sum_j y_j (D_j f_w)(x + \eta y)$, for some $\eta = \eta(y) \in (0, 1)$, for any $y = (y_1, y_2)$ with $||y|| \leq b$. We take $y = \xi_{t+1} - \xi_t = \theta_t$, condition on $\xi_t = x$, and use (3.3) to show, a.s., $|f_w(\xi_{t+1}) - f_w(\xi_t)| = O(||x + \eta \theta(x)||^{w-1})$. Then (A2) implies (3.8).

For the moment estimates, we include more terms in the Taylor expansion to obtain

\[ E[f_w(\xi_{t+1}) - f_w(\xi_t) \mid \xi_t = x] = \sum_j E[\theta_j(x)](D_j f_w)(x) + \frac{1}{2} \sum_j E[\theta_j(x)^2](D_j^2 f_w)(x) + \sum_{i < j} E[\theta_i(x) \theta_j(x)](D_i D_j f_w)(x) + \frac{1}{6} E \left[ \sum_{\sigma : |\sigma| = 3} \theta^\sigma(x)(D_\sigma f_w)(x + \eta \theta(x)) \right], \]

(3.12)

for some $\eta = \eta(\theta_t) \in (0, 1)$. By (A2), $E[\theta_j(x)^3] = O(1)$, so that using (3.7) the final term in (3.12) is $O(r^{w-3})$. Then using (3.3), (3.4) and (3.5) in (3.12), we obtain (3.9).

Similar calculations yield (3.10) and (3.11). \qed

When $\Xi$ has zero drift, one expects that $(f_w(\xi_t))_{t \in \mathbb{Z}^+}$ is ‘almost’ a martingale; we often want either a submartingale or a supermartingale. So, in Lemma 3.3 below, we study the process $(f_w(\xi_t^\gamma))_{t \in \mathbb{Z}^+}$ where $\gamma \in \mathbb{R}$. Recall that for $w < \pi/(2\alpha)$, $f_w(x)$ is positive on a wedge $W(\pi/(2w))$ bigger than $W(\alpha)$. The following result is simple but important.

Lemma 3.2. Suppose that $\alpha \in (0, \pi]$ and $w \in (0, \pi/(2\alpha))$. Then there exists $\varepsilon_{\alpha,w} = \cos(\alpha w) > 0$ such that for all $x \in W(\alpha)$,

\[ \varepsilon_{\alpha,w} r^w \leq f_w(x) \leq r^w. \]

(3.13)

Moreover, for $k \geq 0$ we have that if $w \geq k/2$ then for all $x \in W(\alpha)$,

\[ \cos((w - k)\varphi) \geq \varepsilon_{\alpha,w} > 0. \]

(3.14)

Proof. For fixed $\alpha \in (0, \pi]$ and fixed $w \in (0, \pi/(2\alpha))$ we have

\[ \varepsilon_{\alpha,w} := \inf_{x \in W(\alpha)} \cos(w \varphi) = \inf_{\varphi \in (-\alpha, \alpha)} \cos(w \varphi) = \cos(w \alpha) > 0, \]

since $w \alpha \in (0, \pi/2)$. Then (3.13) follows from (3.2). Similarly, since for $w \geq k/2$ and $k \geq 0$, $-w \leq -k/2 \leq w - k \leq w$, we have $\inf_{x \in W(\alpha)} \cos((w - k)\varphi) \geq \inf_{\varphi \in (-\alpha, \alpha)} \cos(w \varphi) = \varepsilon_{\alpha,w}$, which gives (3.14). \qed
Lemma 3.3. Suppose that \((A2)\) holds. Suppose that \(\alpha \in (0, \pi]\), \(\gamma \in \mathbb{R}\), and \(w \in (0, \pi/(2\alpha))\). Then for all \(x \in \mathcal{W}(\alpha)\) we have that as \(r = ||x|| \to \infty\),

\[
\mathbb{E}[f_w(\xi_{t+1})^\gamma - f_w(\xi_t)^\gamma \mid \xi_t = x] = \gamma f_w(x)^{\gamma-1} w r^{-1} (\mu_1(x) \cos((w - 1)\varphi) - \mu_2(x) \sin((w - 1)\varphi)) + \gamma f_w(x)^{\gamma-1} M_{12}(x) w (w-1) r^{-2} \sin((w - 2)\varphi) + \frac{1}{2} \gamma f_w(x)^{\gamma-1} (M_{11}(x) - M_{22}(x)) w (w-1) r^{-2} \cos((w - 2)\varphi) + \frac{1}{2} \gamma (\gamma - 1) f_w(x)^{\gamma-2} w^2 r^{-2} (M_{11}(x) \cos((w - 1)\varphi) + M_{22}(x) \sin((w - 1)\varphi)) - \frac{1}{2} \gamma (\gamma - 1) f_w(x)^{\gamma-2} w^2 r^{-2} M_{12}(x) \sin(2(w - 1)\varphi) + O(f_w(x)^{\gamma-3} r^{3w-3}).
\]

Proof. Let \(\Delta := f_w(\xi_{t+1}) - f_w(\xi_t)\). Then for \(\gamma \in \mathbb{R}\) and \(x \in \mathcal{W}(\alpha)\),

\[
\mathbb{E}[f_w(\xi_{t+1})^\gamma - f_w(\xi_t)^\gamma \mid \xi_t = x] = f_w(x)^\gamma \mathbb{E}\left[ \left(1 + \frac{\Delta}{f_w(x)}\right)^\gamma - 1 \mid \xi_t = x \right],
\]

and as long as \(\Delta/f_w(x)\) is not too large we can use the fact that for \(\gamma \in \mathbb{R}\) and small \(x\), \((1 + x)^\gamma = 1 + \gamma x + \frac{1}{2} \gamma (\gamma - 1) x^2 + O(x^3)\). Under the conditions of the lemma, for \(x \in \mathcal{W}(\alpha)\) with \(r = ||x||\) large enough, a.s., \(|\Delta/f_w(x)| \leq C r^{-1}/f_w(x) = O(r^{-1})\), using (3.8) and (3.13). Hence for \(\gamma \in \mathbb{R}\) and all \(||x||\) large enough

\[
\mathbb{E}[f_w(\xi_{t+1})^\gamma - f_w(\xi_t)^\gamma \mid \xi_t = x] = \gamma f_w(x)^{\gamma-1} \mathbb{E}[\Delta \mid \xi_t = x] + \frac{1}{2} \gamma (\gamma - 1) f_w(x)^{\gamma-2} \mathbb{E}[\Delta^2 \mid \xi_t = x] + O\left(f_w(x)^{\gamma-3} \mathbb{E}[\Delta^3 \mid \xi_t = x]\right). \tag{3.15}
\]

Then from (3.15), Lemma 3.1, and (3.13) we obtain the desired result. \(\square\)

We will also need the following straightforward result.

Lemma 3.4. Let \(h : \mathbb{R}^2 \to \mathbb{R}\) and \(R \subset \mathbb{R}^2\) be such that \(h(x) \leq 0\) for all \(x \in \mathbb{R}^2 \setminus R\). Set \(\hat{h}(x) := h(x)1_{\{x \in R\}}\). Then for all \(x \in R\) and all \(t \in \mathbb{Z}^+\),

\[
\hat{h}(\xi_{t+1}) - \hat{h}(\xi_t) \geq h(\xi_{t+1}) - h(\xi_t), \text{ on } \{\xi_t = x\}.
\]

Proof. For \(x \in R\) we have on \(\{\xi_t = x\}\) that \(\hat{h}(\xi_{t+1}) - \hat{h}(\xi_t) = h(\xi_{t+1}) - h(\xi_t) - h(\xi_{t+1})1_{\{\xi_{t+1} \notin R\}}\), which yields the result given that \(h(x) \leq 0\) for \(x \notin R\). \(\square\)

4 Critical case: proofs of Theorems 2.1, 2.2, and 2.3

4.1 Overview and statement of upper bound

In this section we prove our main results on moments of \(\tau_\alpha\) in the critical case, Theorems 2.2 and 2.3, and give a self-contained proof of Theorem 2.1 including the case \(\alpha = \pi\) not directly covered by [16]. There are two largely separate arguments. The existence of moments part of Theorem 2.2, as well as Theorem 2.1, will follow from Lemma 4.1 below, which gives an upper bound on the tails of \(\tau_\alpha\). We are not able to use general results such as [1, Theorem 1] to prove Lemma 4.1, although we do use semimartingale tools at several points. On the other hand, for the non-existence part of Theorem 2.2, as well as
Theorem 2.3, we are able to appeal to the general result [1, Corollary 1] after finding a suitable Lyapunov function; in this part of the proof the intuition is encapsulated by the Lyapunov function and there is no natural key lemma to stand alongside Lemma 4.1.

Here is our central result for the ‘existence’ part of the proofs.

**Lemma 4.1.** Suppose that (A1), (A2), and (2.2) hold. Let \( \alpha \in (0, \pi/2) \) and \( \mathbf{x} \in \mathcal{W}(\alpha) \). There exist \( \gamma \in (0, \infty) \), not depending on \( \mathbf{x} \), and \( C \in (0, \infty) \), which does depend on \( \mathbf{x} \), such that for all \( t > 0 \),

\[
\mathbb{P}[\tau_\alpha > t \mid \xi_0 = \mathbf{x}] \leq Ct^{-\gamma}. \tag{4.1}
\]

We outline the remainder of this section. In Section 4.2, we show how Lemma 4.1 gives an almost immediate proof of Theorem 2.1. Central to the proof of Lemma 4.1 is a decomposition of \( \Xi \) based on the regularity condition (A1), described in Section 4.3. Section 4.4 is devoted to a key step in the proof of Lemma 4.1, which is a result on the exit from rectangles (Lemma 4.5 below) that says, loosely speaking, that if the walk starts somewhere near the centre of a rectangle, there is strictly positive probability (uniformly in the size of the rectangle) that the walk will first exit the rectangle via the top/bottom. Here the fact that \( \|\mu(\mathbf{x})\| = O(\|\mathbf{x}\|^{-1}) \) is crucial. This result clarifies the key difference between the one-dimensional and multi-dimensional settings: see the remark after Lemma 4.5. In Section 4.5 we give the proof of Lemma 4.1. Then we turn to the ‘non-existence’ parts of the proof; our main tool is a Lyapunov function introduced in Section 4.6. Finally we complete the proofs of Theorems 2.2 and 2.3 in Section 4.7.

### 4.2 Proof of Theorem 2.1

We establish Theorem 2.1 by studying the behaviour of the walk on a set of 7 overlapping quarter-planes that together span \( \mathcal{W}(\pi) \). Define lattice vectors \( \mathbf{q}_i, i \in \{1, \ldots, 7\} \) by

\[
\mathbf{q}_5 = -\mathbf{q}_1 = \mathbf{e}_1 + \mathbf{e}_2, \quad \mathbf{q}_6 = -\mathbf{q}_2 = \mathbf{e}_2, \quad \mathbf{q}_3 = -\mathbf{q}_7 = \mathbf{e}_1 - \mathbf{e}_2, \quad \mathbf{q}_4 = \mathbf{e}_1.
\]

The perpendiculars of the \( \mathbf{q}_i \) we denote by \( \mathbf{q}_i^\perp = \mathbf{q}_{i+2}, \quad i \in \{1, 2, \ldots, 5\}, \quad \mathbf{q}_6^\perp = -\mathbf{q}_4, \) and \( \mathbf{q}_7^\perp = \mathbf{q}_1 \). For the corresponding unit vectors, write \( \hat{\mathbf{q}}_i := \|\mathbf{q}_i\|^{-1}\mathbf{q}_i \) and \( \hat{\mathbf{q}}_i^\perp := \|\mathbf{q}_i^\perp\|^{-1}\mathbf{q}_i^\perp \); note that \( \|\mathbf{q}_i\| = \|\mathbf{q}_i^\perp\| \), which is 1 for even \( i \) and \( \sqrt{2} \) for odd \( i \).

For \( \beta \in (0, \pi/2) \) and \( i \in \{1, \ldots, 7\} \) let \( W_i(\beta) \) denote the wedge with apex 0, internal angle 2\( \beta \), and principal direction \( \mathbf{q}_i \); that is

\[
W_i(\beta) := \{ \mathbf{x} \in \mathbb{R}^2 : \mathbf{x} \cdot \mathbf{q}_i > 0, |\mathbf{x} \cdot \mathbf{q}_i^\perp| < (\tan \beta)|\mathbf{x} \cdot \mathbf{q}_i| \}. \tag{4.2}
\]

With our existing notation, \( W_4(\alpha) \) is \( \mathcal{W}(\alpha) \); the other \( W_i(\alpha) \) are rotations of \( \mathcal{W}(\alpha) \) through angles \( k\pi/4, k \in \{-1, \pm 2, \pm 3\} \). In the proof of Theorem 2.1 below we will need the quarter-planes \( W_i(\pi/4) \); when it comes to the proof of Theorem 2.2 we need \( W_i(\alpha) \) for \( \alpha \in (0, \pi/2) \). Thus we work in this generality for now. For \( \beta \in (0, \pi/2) \), let

\[
\tau_i(\beta) := \min\{t \in \mathbb{Z}^+ : \xi_t \notin W_i(\beta)\}. \tag{4.3}
\]

**Proof of Theorem 2.1.** It suffices to show that the result holds for \( \alpha = \pi \), i.e., the walk a.s. eventually hits the thickened half-line \( \mathcal{H}_b \). For notational ease let \( Q_i := W_i(\pi/4) \), \( \tau_i := \tau_i(\pi/4) \) for \( i \in \{1, \ldots, 7\} \). Also write \( Q_8 := \mathcal{H}_b \) and \( B := B_A(0) \) for some \( A \in (0, \infty) \).

Suppose that \( \xi_0 \in Q_i \). It follows immediately from Lemma 4.1 that \( \mathbb{P}[\tau_i < \infty] = 1 \), and so \( \Xi \) almost surely exits the initial quadrant \( Q_i \). By the bounded jumps assumption
(A2), the definition (4.2), and an appropriate choice of $A$, we see that at time $\tau_i$, $\xi_{\tau_i}$ is either: (i) in $Q_b$; (ii) in $B$; or (iii) within distance $b$ of the principal axis of either $Q_{t+1}$ or $Q_{t-1}$, working mod 8 for the indices of the $Q_j$s.

In case (ii) or (iii), $\Xi$ exits $B$ or the quadrant whose principal axis it is close to in finite time. In the first case, having left $B$, $\Xi$ is in some quadrant, which it must exit in finite time, again ending up in $B$ or close to the principal axis of some other quadrant. This process repeats, showing that $\Xi$ must, infinitely often, be close to the principal axis of one of the quadrants $Q_i$. Moreover, at such times, the proof of Lemma 4.3 shows that the events that the walk next visits $Q_{t+1}$ each have uniformly positive probability. It follows that $\Xi$ visits each $Q_i$, eventually, a.s., and in particular hits the thickened half-line. 

### 4.3 Decomposition

For a given $i$, we decompose $\Xi$ into a symmetric walk in the $q_i^+$ direction and a residual walk. For $x, y \in \mathbb{Z}^2$, $n \in \mathbb{N}$ and $t \in \mathbb{Z}^+$ let $p(x, y; n) := \mathbb{P}[\xi_{t+n} = y \mid \xi_t = x]$. It follows from (A1) by considering finite combinations of jumps that for each $i \in \{1, 2, \ldots, 7\}$ there exist constants $\gamma_i \in (0, 1/2)$, $n_i, j_i \in \mathbb{N}$ such that

$$\min_{x \in Q_i}\{p(x, x + j_i q_i^+; n_i), p(x, x - j_i q_i^-; n_i)) \geq \gamma_i. \quad (4.4)$$

We fix $i$ and consider the ‘$n_i$-skeleton’ random walk. Set $\xi_i^* := \xi_{tn_i}$; the embedded process $\Xi^* = (\xi_i^*)_{t \in \mathbb{Z}^+}$ is a Markov chain on $S$ with transition probabilities $\mathbb{P}[\xi_{t+1} = y \mid \xi_t = x] = p(x, y; n_i)$, and $\xi_0^* = \xi_0$. The walk $\Xi^*$ inherits regularity from $\Xi$ as follows.

**Lemma 4.2.** Suppose that (A1) and (A2) hold. Then

$$\mathbb{P}[\|\xi_{t+1} - \xi_t^*\| \leq bn_i] = 1; \text{ and } \quad (4.5)$$

$$\mathbb{E}[\|\xi_{t+1} - \xi_t^*\| \cdot \mathbb{1}(\xi_t^* = x) \mid \xi_t^* = x] \geq 2 j_i^2 \|q_i^+\|^2 \gamma_i > 0, \quad (4.6)$$

for all $x \in S$. Moreover, if (2.2) holds, then, for $x \in S$, as $\|x\| \to \infty$,

$$\|\mathbb{E}[\xi_{t+1} - \xi_t^* \mid \xi_t^* = x]\| = O(\|x\|^{-1}). \quad (4.7)$$

**Proof.** The bound (4.5) is immediate from (A2), while (4.6) follows from (4.4). Moreover, it follows from (A2) that,

$$\max_{t_i \leq s \leq (t+1)n_i} \|\xi_s - \xi_t^*\| \leq n_i b, \text{ a.s.}, \quad (4.8)$$

which with (2.2) implies (4.7). 

By (4.4), there exist sequences of random variables $(V_t)_{t \in \mathbb{N}}$ and $(\zeta_t)_{t \in \mathbb{N}}$ such that:

(i) the $(V_t)_{t \in \mathbb{N}}$ are i.i.d. with $V_t \in \{-1, 0, 1\}$, $\mathbb{P}[V_t = 0] = 1 - 2\gamma_i$, and $\mathbb{P}[V_t = -1] = \mathbb{P}[V_t = +1] = \gamma_i$;

(ii) $\zeta_{t+1} \in \mathbb{Z}^2$ with $\mathbb{P}[\zeta_{t+1} = 0 \mid V_t \neq 0] = 1$; and

(iii) we can decompose the jumps of $\Xi^*$ via, for $t \in \mathbb{Z}^+$,

$$\xi_{t+1}^* - \xi_t^* = \zeta_t + V_t j_i q_i^+ + \zeta_{t+1}^*. \quad (4.9)$$
On account of (ii), (4.9) is equivalent to \( \xi^*_t - \xi^*_0 = V_{t+1} j_i q_i^\perp 1_{\{V_{t+1} \neq 0\}} + \zeta_{t+1} 1_{\{V_{t+1} = 0\}} \). Thus we decompose the jump of \( \Xi^* \) at time \( t \) into a symmetric component in the perpendicular direction \( (V_{t+1} j_i q_i^\perp) \), and a residual component \( (\zeta_{t+1}) \), such that at any time \( t \) only one of the two components is present in a particular realization. By (4.9),

\[
\xi^*_t = \xi_0 + \sum_{s=1}^t (V_s j_i q_i^\perp + \zeta_s).
\]

(4.10)

### 4.4 Exit from rectangles

We will use the decomposition of Section 4.3 to establish (in Lemma 4.5 below) how the walk exits from large rectangles aligned in the \( q_i, q_i^\perp \) directions. The outline of the proof of Lemma 4.5 below is as follows. In time \( \lceil \varepsilon N^2 \rceil \), we show that the process driven by \( V_1, V_2, \ldots \) will with positive probability attain distance sufficient to take it well beyond the top/bottom of the rectangle; this is Lemma 4.3 below. On the other hand, we show that in time \( \lceil \varepsilon N^2 \rceil \), for small enough \( \varepsilon > 0 \), the residual process does not stray very far from its initial point with good probability, regardless of the realization of \( V_1, V_2, \ldots \); this is Lemma 4.4 below. Together, these two results will show that with good probability the walk will leave a rectangle via the top/bottom. Set \( Y_0 := \xi_0 \cdot q_i^\perp \) and, for \( t \in \mathbb{N} \),

\[
Y_t := Y_0 + j_t \|q_i^\perp\| \sum_{s=1}^t V_s.
\]

Then \( Y_t \) is the displacement of the symmetric part of the decomposition for \( \xi^*_t \) in the \( q_i^\perp \) direction. The process \( (Y_t)_{t \in \mathbb{Z}^+} \) is a symmetric, homogeneous random walk on \( \|q_i^\perp\| \mathbb{Z} \) with \( \mathbb{P}[Y_t = Y_{t-1}] = \mathbb{P}[V_t = 0] = 1 - 2\gamma_i < 1 \) and jumps of size \( \|q_i^\perp\| j_i \). For \( h \in (0, \infty) \), let

\[
\tau^h := \min \{ t \in \mathbb{Z}^+ : \|Y_t\| \geq \lceil 3hN \rceil \|q_i^\perp\| \}.
\]

(4.12)

**Lemma 4.3.** Suppose that \((A1)\) holds. Let \( h \in (0, \infty) \). For any \( \varepsilon > 0 \), there exist \( \delta > 0 \) and \( N_1 \in \mathbb{N} \) such that for any \( N \geq N_1 \) and any \( y \in \mathbb{Z} \) with \( |y| \leq 2hN \),

\[
\mathbb{P}[\tau^h \leq \lceil \varepsilon N^2 \rceil \mid Y_0 = \|q_i^\perp\| |y| \geq \delta.
\]

**Proof.** Fix \( h \in (0, \infty) \). Suppose \( Y_0 = \| q_i^\perp \| y \), \( |y| \leq 2hN \). If \( y \neq 0 \) then couple a copy of the walk \( Y_t \) started from \( \| q_i^\perp \| y \) with another \( \tilde{Y}_t \) started from \( 0 \) which has jumps in the opposite direction to \( Y_t \) until \( |Y_t - \tilde{Y}_t| \leq \| q_i^\perp \| j_i \) for the first time, from which time on \( Y_t \) and \( \tilde{Y}_t \) jump in the same direction. Then when \( |Y_t| \geq K \) we have \( |Y_t| \geq K - \| q_i^\perp \| j_i \), and with probability \( \gamma_i \) the next jump will take \( |Y_{t+1}| \geq K \). Thus for any \( \varepsilon > 0 \),

\[
\mathbb{P}[\tau^h \leq \lceil \varepsilon N^2 \rceil \mid Y_0 = \| q_i^\perp \| |y| \geq \gamma_i \mathbb{P}[\tau^h \leq \lceil \varepsilon N^2 \rceil - 1 \mid Y_0 = 0] \]

\[
\geq \gamma_i \mathbb{P}[\tau^h \leq \lceil \varepsilon N^2 \rceil \mid Y_0 = 0],
\]

for any \( \varepsilon' \in (0, \varepsilon) \) and all \( N \) large enough. Hence it suffices to take \( y = 0 \).

The process \( (Y_t)_{t \in \mathbb{Z}^+} \) is a symmetric random walk on \( \| q_i^\perp \| \mathbb{Z} \) with independent, bounded jumps and \( \mathbb{E}[|Y_{t+1} - Y_t|^2] = 2\gamma_i \| q_i^\perp \|^2 j_i^2 > 0 \). Standard central limit theorem estimates imply that for any \( \varepsilon > 0 \) there exists \( \delta > 0 \) such that for all \( N \) sufficiently large

\[
\mathbb{P}[Y_{\lceil \varepsilon N^2 \rceil} > \lceil 3hN \rceil \| q_i^\perp \| \mid Y_0 = 0] \geq \delta, \text{ and } \mathbb{P}[Y_{\lceil \varepsilon N^2 \rceil} < \lceil -3hN \rceil \| q_i^\perp \| \mid Y_0 = 0] \geq \delta.
\]

Each of the (disjoint) events in the last display implies that \( \tau^h \leq \lceil \varepsilon N^2 \rceil \). \(\square\)
Let \( Z_0 := (\xi_0 \cdot \hat{\mathbf{q}}_i)\hat{q}_i \) and for \( t \in \mathbb{N} \) let
\[
Z_t := Z_0 + \sum_{s=1}^{t} \zeta_s. \tag{4.13}
\]

Thus \((Z_t)_{t \in \mathbb{Z}^+}\) is the residual part of the process \((\xi^*_t)_{t \in \mathbb{Z}^+}\) after the symmetric perpendicular process \((Y^*_t)_{t \in \mathbb{Z}^+}\) has been extracted. Indeed, with \( Y_t, Z_t \) as defined at (4.11), (4.13) we have \( \xi^*_0 = \xi_0 = Y_0\hat{q}_i + Z_0 \), and also from (4.10) that for \( t \in \mathbb{N} \),
\[
\xi^*_t = Y_t\hat{q}_i + Z_t. \tag{4.14}
\]

We next show that with good probability the residual process \((Z_t)_{t \in \mathbb{Z}^+}\) does not exit from a suitable ball around its initial point by time \([\varepsilon N^2] \). By construction \((Z_t)_{t \in \mathbb{Z}^+}\) depends on \((V_t)_{t \in \mathbb{N}}\) since the distribution of \( \zeta_{t+1} \) depends on \( \xi_{i_m} \). For \( t \in \mathbb{N} \), let \( \Omega_V(t) := \{-1,0,1\}^t \) and let \( \omega_V \in \Omega_V(t) \) denote a generic realization of \((V_1, \ldots, V_t)\).

**Lemma 4.4.** Suppose that (A1), (A2), and (2.2) hold. Let \( r \in (0,1/2] \). There exist \( N_2 \in \mathbb{N} \) and \( \varepsilon > 0 \) such that for all \( N \geq N_2 \), all \( z \in \mathbb{Z} \) with \( |z| \leq b \), and all \( \omega_V \in \Omega_V([\varepsilon N^2]) \),
\[
\mathbb{P}\left[ \max_{0 \leq t \leq [\varepsilon N^2]} \|Z_t - Z_0\| \leq rN \mid (V_1, \ldots, V_{[\varepsilon N^2]}) = \omega_V, Z_0 = (N+z)\hat{q}_i \right] \geq \frac{1}{2}.
\]

**Proof.** Although the decomposition used in the present paper is different, the proof of this result is similar to (in fact, due to the stronger regularity assumptions, simpler than) the proof of the corresponding Lemma 4.5 in [16], so we omit it. \( \square \)

Fix \( h \in (0,\infty) \), which will set the aspect ratio of our rectangles. For \( N \in \mathbb{N} \), let
\[
S(N) := \{ x \in \mathbb{Z}^2 : 0 < x \cdot \hat{\mathbf{q}}_i < 2N\|\hat{\mathbf{q}}_i\|, |x \cdot \hat{\mathbf{q}}_i^\perp| < 2hN\|\hat{\mathbf{q}}_i\| \}, \tag{4.15}
\]
and also define regions adjacent to \( S(N) \) via
\[
U_1(N) := \{ x \in \mathbb{Z}^2 : x \cdot \hat{\mathbf{q}}_i \geq 2N\|\hat{\mathbf{q}}_i\| \},
\]
\[
U_2(N) := \{ x \in \mathbb{Z}^2 : 0 < x \cdot \hat{\mathbf{q}}_i < 2N\|\hat{\mathbf{q}}_i\|, |x \cdot \hat{\mathbf{q}}_i^\perp| \geq 2hN\|\hat{\mathbf{q}}_i\| \}. \tag{4.16}
\]

**Lemma 4.5.** Suppose that (A1), (A2), and (2.2) hold. Let \( h \in (0,\infty) \). Then there exist \( \delta > 0, N_0 \in \mathbb{N} \) such that for any \( N \geq N_0 \), any \( y, z \in \mathbb{Z} \) with \( |y| \leq 2hN \) and \( |z| \leq b \),
\[
\mathbb{P}[\Xi \text{ hits } U_2(N) \text{ before } U_1(N) \mid \xi_0 = (N+z)\hat{q}_i + y\hat{q}_i^\perp] \geq \delta.
\]

**Remark.** Contrast this result with exit from a half-line in one-dimension, where drift \( O(x^{-1}) \) does not imply finiteness of the exit time. The one-dimensional analogue of Lemma 4.5 is false: classical gambler’s ruin estimates imply that for a random walk on \( \mathbb{Z}^+ \) with mean-drift \( O(x^{-1}) \) at \( x \), the probabilities of hitting 0, 2M first, starting from \( M \), are not necessarily bounded uniformly away from 0.

**Proof of Lemma 4.5.** Fix \( h \in (0,\infty) \). Suppose that \( \xi_0 = (N+z)\hat{q}_i + y\hat{q}_i^\perp \). Let \( \varepsilon > 0 \) be as in the \( r = (1 \wedge h)/2 \) case of Lemma 4.4. Suppose that \( N \geq \max\{N_1, N_2\} \) with \( N_1, N_2 \) as in Lemmas 4.3, 4.4 respectively. Define the events
\[
G := \left\{ \max_{0 \leq t \leq [\varepsilon N^2]} \|Z_t - Z_0\| \leq (1 \wedge h)N/2 \right\}, \quad H := \left\{ \tau_h^\perp \leq [\varepsilon N^2] \right\}. \]
By (4.14) we have that $|\xi_i^+ \cdot \hat{q}_i| = |Y_i + Z_i \cdot \hat{q}_i| = |Y_i + (Z_t - Z_0) \cdot \hat{q}_i|$, since $Z_0 \cdot \hat{q}_i = 0$.

It follows by the triangle inequality that on $G \cap H$, 

$$|\xi_i^+ \cdot \hat{q}_i| \geq |Y_i| - ||Z_t - Z_0|| \geq \left[3hN\right]|q_i^+| - (1 \wedge h)(N/2) \geq 2hN|q_i^+|,$$

for some $t \leq \lfloor \varepsilon N^2 \rfloor$, which in particular implies that $|\xi_i^+ \cdot \hat{q}_i| \geq 2hN|q_i^+|$ for some $t \leq n_t\lfloor \varepsilon N^2 \rfloor$. Also on $G \cap H$, it follows from (4.8) and (4.14) that 

$$\max_{0 \leq t \leq n_t\lfloor \varepsilon N^2 \rfloor} |\xi_i^+ \cdot \hat{q}_i| \leq \max_{0 \leq t \leq \lfloor \varepsilon N^2 \rfloor} |\xi_i^+ \cdot \hat{q}_i| + n_t b = \max_{0 \leq t \leq \lfloor \varepsilon N^2 \rfloor} |Z_t \cdot \hat{q}_i| + n_t b \leq |Z_0 \cdot \hat{q}_i| + \max_{0 \leq t \leq \lfloor \varepsilon N^2 \rfloor} ||Z_t - Z_0|| + n_t b < 2N|q_i^+|,$$

for all $N$ sufficiently large, since $Z_0 \cdot \hat{q}_i = \xi_0 \cdot \hat{q}_i = (N + z)|q_i|$. Hence (with $\xi_0$ as given) 

$$E := \{ \Xi \text{ hits } U_2(N) \text{ before } U_1(N) \} \supseteq G \cap H.$$

$H$ is determined by the realization $\omega_\gamma \in \Omega_\gamma(\lfloor \varepsilon N^2 \rfloor)$, and so (with $\xi_0$ as given)

$$\mathbb{P}[E] \geq \mathbb{P}[G \cap H] = \sum_{\omega_\gamma \in \Omega_\gamma(\lfloor \varepsilon N^2 \rfloor): H \text{ occurs}} \mathbb{P}[G | \omega_\gamma] \mathbb{P}[\omega_\gamma].$$

Applying Lemma 4.4 with $r = (1 \wedge h)/2$ to $\mathbb{P}[G | \omega_\gamma]$ we then obtain 

$$\mathbb{P}[E | \xi_0 = (N + z)q_i + yq_i^+] \geq \frac{1}{2} \sum_{\omega_\gamma \in \Omega_\gamma(\lfloor \varepsilon N^2 \rfloor): H \text{ occurs}} \mathbb{P}[\omega_\gamma] = \frac{1}{2} \mathbb{P}[H] \geq \frac{\delta}{2} > 0,$$

applying Lemma 4.3. \hfill \Box

### 4.5 Exit from cones: proof of Lemma 4.1

We can now prove our key upper tail bound. Recall the definition of $\tau_i(\beta)$ from (4.3).

**Proof of Lemma 4.1.** Take $\xi_0 \in W_i(\beta)$, $\beta \in (0, \pi/2)$. Let $h = \tan \beta \in (0, \infty)$ and 

$$k_0 := \min\{ k \in \mathbb{N} : 2^k\|q_i\| \geq \xi_0 \cdot \hat{q}_i, 2^k \geq N_0, 2^k \geq b \},$$

where $N_0$ is as in Lemma 4.5 and $b$ is as in (A2). Consider the sequence of rectangles $S(2^k) \text{ where } k \in \mathbb{Z}^+$, as defined at (4.15), with $h = \tan \beta$. Set $\sigma_0 := 0$ and, for $k \in \mathbb{N}$, 

$$\sigma_k := \min\{ t \in \mathbb{Z}^+ : \xi_t \cdot \hat{q}_i \geq 2^k\|q_i\| \}. $$

Suppose that $\Xi$ has not left $W_i(\beta)$ by the time $\sigma_k$ for some $k \geq k_0$, i.e., $\tau_i(\beta) > \sigma_k$. Then, using (A2), $2^k\|q_i\| \leq \xi_\sigma \cdot \hat{q}_i \leq 2^k\|q_i\| + b$ and on $\{ \tau_i(\beta) > \sigma_k \}$, from (4.2), 

$$|\xi_\sigma \cdot \hat{q}_i| < h|\xi_\sigma \cdot \hat{q}_i| \leq 2^k h\|q_i\| + hb \leq 2 \cdot 2^k h\|q_i\|,$$

for all $k \geq k_0$. Hence we can apply Lemma 4.5 to the walk started at $\xi_\sigma$, with $N = 2^k \geq N_0$ for $k \geq k_0$. Then, with $U_1(N), U_2(N)$ as defined in (4.16), we obtain, for all $k \geq k_0$,

$$\mathbb{P}[(\xi_t)_{t \geq \sigma_k} \text{ hits } U_2(2^k) \text{ before } U_1(2^k) | \tau_i(\beta) > \sigma_k] \geq \delta > 0.$$ 

But by definition of $U_1(N), U_2(N)$, and (4.2), we have that if $\Xi$ hits $U_2(N)$ before $U_1(N)$, then $\Xi$ leaves the wedge $W_i(\beta)$. Moreover, if $\Xi$ has not hit $U_1(2^k)$ by time $\tau_i(\beta)$, then
\[ \max_{0 \leq t \leq \tau_\beta} \xi_t \cdot \hat{q}_t < 2^{k+1}\|q_t\|, \] so that \( \tau_\beta < \sigma_{k+1} \). Hence the inequality (4.17) can be expressed as
\[ \mathbb{P}[\tau_\beta \leq \sigma_{k+1} \mid \tau_\beta > \sigma_k] \geq \delta > 0, \] for all \( k \geq k_0 \). So, for all \( k > k_0 \),
\[ \mathbb{P}[\tau_\beta > \sigma_k] = \prod_{j=k_0+1}^k \mathbb{P}[\tau_\beta > \sigma_j \mid \tau_\beta > \sigma_{j-1}] \cdot \mathbb{P}[\tau_\beta > \sigma_{k_0}] \leq C(1-\delta)^k, \] (4.18)
for some \( C = C(k_0, \delta) \in (0, \infty) \) that does not depend on \( k \).

We next estimate the tails of the times \( \sigma_k \). It is most convenient to work once again via the embedded walk \( \Xi^* \). Set \( \sigma^*_k := \min\{t \in \mathbb{Z}^+ : \xi_t \cdot \hat{q}_t \geq 2^k \|q_t\|\} \). For \( t \in \mathbb{Z}^+ \), for the remainder of this proof write \( X_t := \xi_t \cdot \hat{q}_t \). Let \( A, C > 0 \) and set \( W_t := ((C + X_t\tau_\beta)^A) \). We show that for \( A, C \) sufficiently large, the process \((W_t)_{t \in \mathbb{Z}^+}\) is a strict submartingale so that we can apply a result from [18] to obtain a bound for \( \mathbb{E}[\tau_\beta \wedge \sigma^*_k] \).

Taylor’s theorem implies that for any \( x \geq 0 \) and any \( y \in \mathbb{R} \) with \( |y| \) bounded,
\[ (C + x + y)^A - (C + x)^A = A(C + x)^{A-1} \left[ y + \frac{(A-1)y^2}{2(C + x)} + O((C + x)^{-2}) \right]. \]

Set \( \theta^*_t = \xi^*_t - \xi_t \). Let \( \mathcal{F}_t = \sigma(\xi_0, \ldots, \xi_t) \). By (4.5) we may apply the last displayed equation with \( x = \xi^*_t \cdot \hat{q}_t \) and \( y = \theta^*_t \cdot \hat{q}_t \) and take expectations to obtain
\[ \mathbb{E}[W_{t+1} - W_t \mid \mathcal{F}_{n,t}] = A(C + X_t)^{A-1} \left[ \mathbb{E}[\theta^*_t \cdot \hat{q}_t \mid \mathcal{F}_{n,t}] + \frac{(A-1)}{2} \frac{\mathbb{E}[(\theta^*_t \cdot \hat{q}_t)^2 \mid \mathcal{F}_{n,t}]}{C + X_t} + O((C + X_t)^{-2}) \right], \]
on \( \{t < \tau_\beta\} \). Also, on \( \{t < \tau_\beta\} \) we have that \( X_t \geq 0 \) and \( X_t \leq \|\xi^*_t\| \leq O(X_t) \). So using (4.6) and (4.7) we have that the last displayed expression is bounded below by
\[ A(C + X_t)^{A-1} \left[ -C_1(1 + X_t)^{-1} + \frac{(A-1)}{C_2} \frac{(C + X_t)^{-1} + O((C + X_t)^{-2})}{C + X_t} \right], \]
for some constants \( C_1, C_2 \in (0, \infty) \). Hence we can choose \( A, C \) sufficiently large so that \( \mathbb{E}[W_{t+1} - W_t \mid \mathcal{F}_{n,t}] \geq \varepsilon > 0 \), on \( \{t < \tau_\beta\} \). Moreover, from (4.5) we have \( |X_{t+1} - X_t| \leq \|\xi^*_t - \xi^*_t\| \leq n_b \). Hence we can apply a straightforward modification of [18, Lemma 3.2] to obtain, for all \( k \geq k_0 \), \( \mathbb{E}[\tau_\beta \wedge \sigma^*_k] \leq \varepsilon^{-1}(C + 2^{k+1} + n_b)^A \). By definition of \( \xi^*_t \), \( \sigma_k \leq n \sigma^*_k \) a.s., hence there exists \( C \in (0, \infty) \) such that \( \mathbb{E}[\tau_\beta \wedge \sigma_k] \leq 2^{kC} \), for all \( k \geq k_0 \). Markov’s inequality with \( M = C + 1 \) then implies that for \( k \geq k_0 \),
\[ \mathbb{P}[\tau_\beta \wedge \sigma_k > 2^{kM}] \leq 2^{-kM} \mathbb{E}[\tau_\beta \wedge \sigma_k] \leq 2^{kC} \cdot 2^{-kM} = 2^{-k}. \]
Combining this with (4.18) and the fact that for any \( k \), \( \mathbb{P}[\tau_\beta > 2^{kM}] \leq \mathbb{P}[\tau_\beta > \sigma_k] + \mathbb{P}[\tau_\beta \wedge \sigma_k > 2^{kM}] \), we obtain \( \mathbb{P}[\tau_\beta > 2^{kM}] \leq C(1-\delta)^k + 2^{-k} \) for all \( k \geq k_0 \). It follows that there exist constants \( M, \gamma' \in (0, \infty) \), not depending on \( x \), and \( C \in (0, \infty) \), which depends on \( x \), such that for all \( k \geq k_0 \),
\[ \mathbb{P}[\tau_\beta > 2^{kM} \mid \xi_0 = x] \leq C 2^{-\gamma' k}. \] (4.19)
Clearly the result extends to all \( k \in \mathbb{Z}^+ \) for a suitable choice of \( C \) in (4.19), depending on \( k_0 \) and so also on \( \xi_0 \). For any \( t > 0 \), we have that \( t \in [2^{kM}, 2^{(k+1)M}] \) for some \( k \in \mathbb{Z}^+ \). Then given \( \xi_0 = x \) we have from (4.19) that
\[ \mathbb{P}[\tau_\beta > t] \leq \mathbb{P}[\tau_\beta > 2^{kM}] \leq C 2^{-\gamma' k} \leq C(2^{-M} t)^{-\gamma' / M} = C't^{-\gamma}, \]
for some \( C', \gamma' \in (0, \infty) \), not depending on \( t \), with, moreover, \( \gamma \) not depending on \( x \). \( \square \)
4.6 Non-existence of moments via an almost-linear Lyapunov function

For our proof of the non-existence part of Theorem 2.2, which will also yield Theorem 2.3, we consider the embedded walk $\xi^*_t = \xi_{nt}$ in $\mathcal{W}(\alpha)$, $\alpha \in (0, \pi/2)$, where now we take $n_t = n_0$ as in (A1). We first show that for any $\alpha \in (0, \pi/2)$ there exists $p \in (0, \infty)$ such that $\mathbb{E}[\tau^p_0] = \infty$. Our approach is based on a one-dimensional process given by $Y_t = g(\xi^*_t)$ for a suitably chosen almost linear or $\varepsilon$-linear (in the sense of Malyshev [17], see also [10] and [5, Chapter 3]) function $g$ to enable us to apply [1, Corollary 1]. The level curves of $g$ will be horizontal translates of $\partial \mathcal{W}(\alpha)$ but with the apex replaced by a circular arc.

Fix $\alpha \in (0, \pi/2)$. During the remainder of this section, set $s := \sin \alpha \in (0, 1)$, $c := \cos \alpha \in (0, 1)$. We now construct the function $g : \mathbb{R}^2 \to [0, \infty)$. Set $g(x) = 0$ for $x \in \mathbb{R}^2 \setminus \mathcal{W}(\alpha)$. For $x = (x_1, x_2) \in \mathcal{W}(\alpha)$ such that $|x_2| \geq \frac{2s}{1+c^2}x_1$ let $g(x) = sx_1 - c|x_2|$. For $x \in \mathcal{W}(\alpha)$ with $|x_2| \leq \frac{2s}{1+c^2}x_1$, set $g(x) = k \in [0, \infty)$ on the minor arc of the circle

$$((2k/s) - x_1)^2 + x_2^2 = k^2$$

between $(k(1+c^2)/s, kc)$ and $(k(1+c^2)/s, -kc)$. Then $g$ is specified on $\mathcal{W}(\alpha)$ by its level curves $g(x) = k$, $k \geq 0$, each of which is $\partial \mathcal{W}(\alpha)$ translated so that the apex is at $(k/s, 0)$ and the tip of the wedge smoothed to a circular arc. Observe that for $x \in \mathbb{R}^2$,

$$g(x) \leq \|x\|. \tag{4.21}$$

For $x \in \mathcal{W}(\alpha)$ with $|x_2| \geq \frac{2s}{1+c^2}x_1$, $\nabla g(x) = (s, \pm c)$ and $\|\nabla g(x)\| = 1$; for $|x_2| \leq \frac{2s}{1+c^2}x_1$,

$$\nabla g(x) = \frac{1}{D(x)}\left(-(2g(x)/s - x_1), x_2\right) = \frac{1}{D(x)}\left(-\sqrt{g(x)^2 - x_2^2}, x_2\right), \tag{4.22}$$

from (4.20), where $D(x) := g(x) + (2/s)(x_1 - (2g(x)/s))$. When $|x_2| \leq \frac{2s}{1+c^2}x_1$, so that the level curve of $g$ is a circular arc, we have

$$g(x)((2/s) - 1) \leq x_1 \leq g(x)((2/s) - s), \text{ and} \tag{4.23}$$

$$-g(x)((2/s) - 1) \leq D(x) \leq -g(x). \tag{4.24}$$

It follows from (4.22) that for $x \in \mathcal{W}(\alpha)$ with $|x_2| \leq \frac{2s}{1+c^2}x_1$, $\|\nabla g(x)\| = |D(x)|^{-1}g(x)$. Hence from (4.24),

$$\inf_{x \in \mathcal{W}(\alpha)} \|\nabla g(x)\| \geq \frac{s}{2-s} \geq \frac{s}{2}, \text{ and } \sup_{x \in \mathbb{R}^2} \|\nabla g(x)\| \leq 1. \tag{4.25}$$

We will apply [1, Corollary 1] to $g(\xi^*_t)$. The next lemma gives some further properties of $g$ needed here and later in the proof of Theorem 2.3.

**Lemma 4.6.** For $x \in \mathcal{W}(\alpha)$ with $|x_2| \leq \frac{2s}{1+c^2}x_1$ we have

$$g(x) \geq \frac{s}{2}\|x\|. \tag{4.26}$$

Also, there exists $\varepsilon > 0$ such that for all $x \in \mathcal{W}(\alpha)$,

$$D_1g(x) \geq \varepsilon. \tag{4.27}$$

Finally, there exists $C \in (0, \infty)$ such that for all $x \in \mathbb{R}^2$ and all $i,j \in \{1, 2\}$,

$$|D_{ij}g(x)| \leq C\|x\|^{-1}. \tag{4.28}$$
Proof. To obtain (4.26), we observe that for \( |x_2| \leq \frac{sc}{1+c^2} x_1 \), from (4.23),
\[
\|x\|^2 \leq \left( \frac{sC}{1+c^2} \left( (2/s - s)^2 + (2/s - s)^2 \right) \right)^2 + \left( (2/s - s)^2 \right)^2 \geq (4/s^2 - 3)g(x)^2,
\]
and (4.26) follows. Consider (4.27). It suffices to suppose \( |x_2| \leq \frac{sc}{1+c^2} x_1 \). By (4.22),
\[
D_1 g(x) = \frac{2g(x) - sx_1}{(4/s - s)g(x) - 2x_1} = R \left[ 1 + \frac{Sx_1}{g(x) - Rx_1} \right],
\]
where \( R \in (0, 2/3) \) and \( S \in (0, 1/6) \) are defined as
\[
R = \frac{2}{(4/s - s)}, \quad \text{and} \quad S = R - (s/2) = \frac{s}{2} \left( \frac{s^2/4}{1 - (s^2/4)} \right).
\]
Here, since \( s \in (0, 1) \), it is straightforward to show that in fact
\[
\frac{s}{2} \leq R \leq \frac{2s}{3}, \quad \text{and} \quad \frac{s^2}{8} \leq S \leq \frac{s^2}{6}.
\]
Moreover, we have from (4.30) and (4.23) that
\[
(s^2/4)g(x) \leq g(x) - Rx_1 \leq (s/2)g(x).
\]
It follows from (4.29) and (4.32) that \( D_1 g(x) \geq R \), and so with (4.31) we get (4.27).

Now consider (4.28). Note that \( D_{ij}(x) = 0 \) unless \( x \in \mathcal{W}(\alpha) \) with \( |x_2| \leq \frac{sc}{1+c^2} x_1 \), so it suffices to consider that case. First consider \( D_{11} g(x) \). Differentiating in (4.29) yields
\[
D_{11} g(x) = \frac{RS}{(g(x) - Rx_1)^3} \left( (g(x) - Rx_1)^2 - RSx_1^2 \right).
\]
Then from (4.33), using (4.31), (4.32), and (4.23), together with (4.26), we obtain (4.28) in the case \( i = j = 1 \). The other cases of (4.28) follow similarly. 

\subsection{4.7 Proofs of Theorems 2.2 and 2.3}

The next result gives some basic properties of the process \((g(\xi^*_t))_{t \in \mathbb{Z}^+}\).

\textbf{Lemma 4.7.} Suppose that (A1), (A2) and (2.2) hold. Then there exist \( B, C \in (0, \infty) \) and \( \epsilon > 0 \) for which, for any \( x \in \mathcal{W}(\alpha) \),
\[
\mathbb{P}[|g(\xi^*_{t+1}) - g(\xi^*_t)| \leq B] = 1; \quad (4.34)
\]
\[
|\mathbb{E}[g(\xi^*_{t+1}) - g(\xi^*_t) | \xi^*_t = x]| \leq C\|x\|^{-1}; \quad (4.35)
\]
\[
\mathbb{E}[(g(\xi^*_{t+1}) - g(\xi^*_t))^2 | \xi^*_t = x] \geq \epsilon. \quad (4.36)
\]

\textbf{Proof.} The mean value theorem for functions of two variables implies that
\[
g(\xi^*_{t+1}) - g(\xi^*_t) = (\xi^*_{t+1} - \xi^*_t) \cdot \nabla g(z), \quad (4.37)
\]
where \( z = \xi^*_t + \eta(\xi^*_{t+1} - \xi^*_t) \) for some \( \eta \in [0, 1] \). So (4.37) implies that \( |g(\xi^*_{t+1}) - g(\xi^*_t)| \leq \|\xi^*_{t+1} - \xi^*_t\| \), a.s., by (4.25), which with (4.5) yields (4.34). Similarly, (4.37) with (4.25) and (4.7) implies (4.35). Finally, using (A1) we have from (4.37) that for \( x \in \mathcal{W}(\alpha) \),
\[
\mathbb{E}[(g(\xi^*_{t+1}) - g(\xi^*_t))^2 | \xi^*_t = x] \geq \kappa|k_1 e_1 \cdot \nabla g(z_1)|^2,
\]
where \( z_1 = x + \eta_k k_1 e_1 \), for some \( \eta_k \in [0, 1] \); so in particular \( z_1 \in \mathcal{W}(\alpha) \). Thus, by (4.27),
\[
\mathbb{E}[(g(\xi^*_{t+1}) - g(\xi^*_t))^2 | \xi^*_t = x] \geq \kappa k_1^2 \epsilon^2 > 0, \quad \text{giving (4.36).} \]
Now we verify that \( g(\xi^*_t) \) satisfies the conditions of [1, Corollary 1].

**Lemma 4.8.** Suppose that \((A1), (A2)\) and \((2.2)\) hold. Let \( Y_t = g(\xi^*_t) \). For \( A > 0 \) large enough there exist \( C, D \in (0, \infty) \), \( r > 1 \), and \( p_0 > 0 \) such that on \( \{ v_A > t \} \),

\[
\begin{align*}
\mathbb{E}[Y_{t+1}^{2p_0} - Y_t^{2p_0} | \mathcal{F}_t] & \geq 0; \\
\mathbb{E}[Y_{t+1}^2 - Y_t^2 | \mathcal{F}_t] & \geq -C; \\
\mathbb{E}[Y_{t+1}^{2r} - Y_t^{2r} | \mathcal{F}_t] & \leq Dy_t^{2r-2}.
\end{align*}
\]

**Proof.** Let \( Y_t = g(\xi^*_t), t \in \mathbb{Z}^+ \). Let \( r > 0 \). We need to estimate \( \mathbb{E}[Y_{t+1}^{2r} - Y_t^{2r} | \xi^*_t = x] \).

By Taylor’s theorem, for \( y > 0 \) and \( \delta \in [0, 1] \) for which

\[
(y + \delta)^{2r} - y^{2r} = 2r\delta y^{2r-1} + r(2r-1)\delta^2(y + \eta\delta)^{2r-2} = 2r\delta y^{2r-1} + r(2r-1)\delta^2y^{2r-2} + o(y^{2r-2}).
\]

We now establish (4.39). Let \( r = 1 \) in (4.41) to obtain

\[
\mathbb{E}[Y_{t+1}^2 - Y_t^2 | \xi^*_t = x] \geq 2g(x)\mathbb{E}[Y_{t+1} - Y_t | \xi^*_t = x] \geq -2Cg(x)x^{-1},
\]

by (4.35). Then (4.21) completes the proof of (4.39). Now let \( \mathcal{F}_t = \sigma(\xi^*_0, \ldots, \xi^*_t) \). Then, by the \( r > 1 \) case of (4.41), \( \mathbb{E}[Y_{t+1}^{2r} - Y_t^{2r} | \mathcal{F}_t] \) is bounded above by

\[
2rg(x)2r-1\mathbb{E}[Y_{t+1} - Y_t | \mathcal{F}_t] + 2r^2\mathbb{E}[(Y_{t+1} - Y_t)^2 | \mathcal{F}_t](Y_t + B)^{2r-2}.
\]

On \( \{ v_A > t \}, g(\xi^*_t) > A \) so \( \xi^*_t \in \mathcal{W}(\alpha) \). So by (4.34) and (4.35), on \( \{ v_A > t \} \),

\[
\mathbb{E}[Y_{t+1}^{2r} - Y_t^{2r} | \mathcal{F}_t] \leq 2CrY_t^{2r-1}\|\xi^*_t\|^{-1} + 2r^2B(Y_t + B)^{2r-2} = O(Y_t^{2r-2}),
\]

by (4.40). Thus (4.40) is satisfied for \( r > 1 \). Similarly, taking \( r = p_0 \) in (4.41) and using (4.35) again, but this time using the lower bound in (4.36), valid on \( \{ v_A > t \}, \)

\[
\mathbb{E}[Y_{t+1}^{2p_0} - Y_t^{2p_0} | \mathcal{F}_t] \geq -2p_0C\|\xi^*_t\|^{-1} + p_0(2p_0 - 1)\|Y_t^{2r-2} + o(Y_t^{2r-2})
\]

\[
\geq Y_t^{2r-2}p_0(-2C + (2p_0 - 1)\varepsilon + o(1)),
\]

by (4.21), which is non-negative on \( \{ v_A > t \} \), taking \( A \) and \( p_0 \) sufficiently large. \( \square \)

We need one more result that says, under our regularity conditions, an asymptotically zero drift ensures that the walk cannot be forced to jump straight out of the wedge with probability 1, provided it starts far enough away from 0.

**Lemma 4.9.** Suppose that \((A1)\) and \((A2)\) hold and that \( \| \mu(x) \| \to 0 \) as \( \| x \| \to \infty \). Let \( \alpha \in (0, \pi) \). There exist \( \varepsilon, A, C \in (0, \infty) \) such that for any \( x \in \mathcal{W}(\alpha) \) with \( \| x \| \geq A \),

\[
\mathbb{P}[\exists \epsilon \text{ hits } B_C(\| x \|, 0) \text{ before } \mathbb{R}^2 \setminus \mathcal{W}(\alpha) | \xi_0 = x] > 0.
\]

**Proof.** Let \( d(x) \) denote the distance of \( x \) from the boundary of the wedge \( \mathcal{W}(\alpha) \). Suppose that \( x \in \mathcal{W}(\alpha) \) and, without loss of generality, \( x_2 > 0 \). First let \( \alpha < \pi/2 \). Given \( d(x) > bn_0 \), condition (A1) implies that with probability at least \( \kappa \) the walk starting at \( x \in \mathcal{W}(\alpha) \) will end up at \( x - ke_2 \) in \( n_0 \) steps, while during this time (A2) implies the walk cannot have left the wedge. Repeating this argument a finite number of times (depending on \( x \)) until the desired ball is reached leads to the desired conclusion for all such \( x \). A similar argument works when \( \alpha \geq \pi/2 \) and \( d(x) > bn_0 \), starting with steps of \( ke_1 \).
Thus it remains to deal with the case where the walk starts at \( x \) with \( d(x) \leq bn_0 \) but \( \|x\| \) large. Recall (see [18, p. 4]) that (A1) implies that \( \mathbb{P}[\xi_t+1 \neq x \mid \xi_t = x] \) is uniformly positive. We may suppose that \( x \) is such that \( \mathbb{P}[(\xi_{t+1} - \xi_t) \cdot e_\perp(\alpha) \neq 0 \mid \xi_t = x] > 0 \), since if this is not the case then (A1) entails that there is positive probability of the walk reaching such an \( x \) in a finite number of jumps parallel to the boundary of the wedge (and hence, by (A2), remaining inside \( \mathcal{W}(\alpha) \) provided the walk started far enough from \( 0 \)). So we may take \( x \) such that there is positive probability of the next jump having a component perpendicular to the wedge boundary. In fact, for \( \|x\| \) large enough, we have \( \mathbb{P}[(\xi_{t+1} - \xi_t) \cdot e_\perp(\alpha) < 0 \mid \xi_t = x] > 0 \), so that there is positive probability of the walk jumping 'farther into' the wedge. To see this, note that since \( \Xi \) lives on (a subset of) \( \mathbb{Z}^2 \), and by (A2), has uniformly bounded jumps there are only finitely many possible values for \( \xi_{t+1} - \xi_t \), and so any non-zero component in the \( e_\perp(\alpha) \) direction must in fact be greater in absolute value than some \( \delta > 0 \) not depending on \( x \). Then

\[
\mu(x) \cdot e_\perp(\alpha) \geq \delta \mathbb{P}[(\xi_{t+1} - \xi_t) \cdot e_\perp(\alpha) \geq \delta \mid \xi_t = x] = 0 \mathbb{P}[(\xi_{t+1} - \xi_t) \cdot e_\perp(\alpha) < \delta \mid \xi_t = x].
\]

Take \( \|x\| \) large enough so that \( \|\mu(x)\| \leq \varepsilon \). Writing \( p = \mathbb{P}[(\xi_{t+1} - \xi_t) \cdot e_\perp(\alpha) \geq \delta \mid \xi_t = x] \) we have \( \varepsilon \geq \delta p - b(1 - p) \), implying that \( p < 1 \) for \( \varepsilon \) small enough. For \( \|x\| \) large enough, a finite number of such jumps occur with positive probability and take \( \Xi \) to distance at least \( bn_0 \) from the boundary of \( \mathcal{W}(\alpha) \); we then appeal to the first part of the proof.

**Proof of Theorem 2.2.** Let \( \alpha \in (0, \pi/2) \). It suffices to show that \( \mathbb{E}[\tau^{\gamma}_n] = \infty \) and \( \mathbb{E}[\tau^{\gamma}_n] < \infty \) for some \( p, q \) with \( 0 < q < p < \infty \). First, we apply Lemma 4.1 in the case \( i = 4, \beta = \alpha \), so that \( \mathcal{W}(\beta) = \mathcal{W}(\alpha) \) and \( \tau(\beta) = \tau(\alpha) \). Then from Lemma 4.1, for some \( \gamma, C \in (0, \infty) \), where \( \gamma \) does not depend on \( x \),

\[
\mathbb{E}[\tau^{\gamma} \mid \xi_0 = x] \leq 1 + \int_{1}^{\infty} \mathbb{P}[\tau > r^{1/q}]dr \leq 1 + C \int_{1}^{\infty} r^{-\gamma/q}dr < \infty,
\]

provided \( q \in (0, \gamma') \). Finally, Lemma 4.8 implies that we can apply [1, Corollary 1] to show that for some \( A, p \in (0, \infty) \), \( \mathbb{E}[\tau^{\gamma}_n \mid \xi_0 = x] = \infty \) for all \( x \in \mathcal{W}(\alpha) \) with \( g(x) \) sufficiently large. But by definition of \( g \) and \( \Xi^* \), and (A2), \( \tau^*_n = n_0(\nu_A - 1) \), a.s., for \( A > b \). Hence \( \mathbb{E}[\tau^{\gamma}_n \mid \xi_0 = x] = \infty \) for all \( x \in \mathcal{W}(\alpha) \) with \( g(x) \) sufficiently large. By Lemma 4.9, the conclusion extends to all \( x \in \mathcal{W}(\alpha) \) with \( \|x\| \) large enough.

To prove Theorem 2.3, we argue similarly to the non-existence part of Theorem 2.2; we refine the lower bound in (4.35) that depends explicitly upon the constant \( c \) in (2.3).

**Lemma 4.10.** Suppose that (A1) and (A2) hold, and that \( \alpha \in (0, \pi/2) \). Suppose that (2.3) holds for some \( c > 0 \). Then there exist \( \varepsilon, C \in (0, \infty) \), not depending on \( d \), such that for all \( x \in \mathcal{W}(\alpha) \) with \( \|x\| \) sufficiently large

\[
\mathbb{E}[g(\xi^*_t) - g(\xi^*_t) \mid \xi^*_t = x] \geq \|x\|^{-1}(\varepsilon c - C).
\]

**Proof.** Write \( \xi^*_t - \xi^*_t = (\theta^*_t(\xi^*_t), \theta^*_t(\xi^*_t)) \) in Cartesian components. Given \( \xi^*_t = x \), (4.8) holds with \( n_i = n_0 \), so (2.3) implies that \( \mathbb{E}[\theta^*_t(x)] \geq (n_0 c + \alpha(1))\|x\|^{-1} \) and \( \mathbb{E}[\theta^*_t(x)] = o(\|x\|^{-1}) \). Conditional on \( \xi^*_t = x \), Taylor’s theorem gives

\[
g(\xi^*_t) - g(\xi^*_t) = \sum_i \theta^*_t(x)D_i g(x) + \frac{1}{2} \sum_{i,j} \theta^*_t(x)\theta^*_t(x)D_{ij} g(x),
\]
for some \( z \in \mathbb{R}^2 \). Then taking expectations and using (4.25), (4.28), and (A2), we have

\[
\mathbb{E}[g(\xi_{t+1}^*) - g(\xi_t^*) \mid \xi_t^* = x] \geq \frac{n_0 c + o(1)}{|x|} D_1 g(x) - \frac{C}{|x|}.
\]

Then (4.27) completes the proof. \( \square \)

**Proof of Theorem 2.3.** Again we apply [1, Corollary 1] to \( g(\xi_t) \). Repeating the argument for Lemma 4.8, (4.39) and (4.40) hold as before, but now using Lemma 4.10 we have that (4.38) holds for \( p_0 = 1/2 \), taking \( c \) sufficiently large. \( \square \)

## 5 Subcritical case: proof of Theorem 2.4

### 5.1 Overview

In this section we prove Theorem 2.4. The techniques used in Sections 4.5 and 4.6 do not give sharp exponents, since they assume very general conditions on \( \Xi \); instead we use the Lyapunov functions \( f_w \) defined at (3.2). In Section 5.2 we prepare for the proof of Theorem 2.4(i) which we present in Section 5.3. The more difficult problem of nonexistence of moments needs more work. Preliminary calculations are in Section 5.4. We are not able to use the general result [1, Corollary 1], so we use a more elementary approach based on a lower bound for the probability that the walk takes a certain time to exit a wedge (Section 5.5). The proof of Theorem 2.4(ii) is completed in Section 5.6.

### 5.2 Existence of moments

Given \( \alpha \in (0, \pi] \), fix \( w \in (0, \pi/(2\alpha)) \); then \( \mathcal{W}(\alpha) \subset \mathcal{W}(\pi/(2w)) \). Define \( \tilde{\Xi} = \{ \tilde{\xi}_t \}_{t \in \mathbb{Z}^+} \) by \( \tilde{\xi}_t := \xi_t 1_{t \leq \tau_{a}} \), so that \( \tilde{\Xi} \) is identical to \( \Xi \) on \( \mathcal{W}(\alpha) \) but from \( x \notin \mathcal{W}(\alpha) \) jumps to \( 0 \); \( \tilde{\xi}_t = 0 \) for \( t \geq \tau_{a} + 1 \). For \( t \in \mathbb{Z}^+ \), set \( X_t := f_w(\tilde{\xi}_t)^{1/w} \). For \( B \in (0, \infty) \), define

\[
\tilde{\tau}_{a,B} := \min \{ t \in \mathbb{Z}^+ : X_t \leq B \}.
\]

**Lemma 5.1.** Suppose that (A1) and (A2) hold. Fix \( \alpha \in (0, \pi] \) and \( w \in (0, \pi/(2\alpha)) \). Suppose that there exist \( p_0 > 0 \), \( A_0, C \in (0, \infty) \) such that for all \( x \in \mathcal{W}(\alpha) \) with \( |x| \geq A_0 \),

\[
\mathbb{E}[f_w(\xi_{t+1})^{2p_0/w} - f_w(\xi_t)^{2p_0/w} \mid \xi_t = x] \leq -C f_w(x)^{(2p_0 - 2)/w}.
\]

Then for any \( p \in [0, p_0) \) and any \( x \in \mathcal{W}(\alpha) \), \( \mathbb{E}[\tau_{a}^p \mid \xi_0 = x] < \infty \).

**Proof.** \( \tilde{\tau}_{a+1} = 0 \) so \( X_{\tau_{a+1}} = 0 \); hence, for any \( B > 0 \), \( \tilde{\tau}_{a,B} \leq \tau_{a} + 1 \) a.s., and

\[
\{ \tilde{\tau}_{a,B} > t \} \subseteq \{ \tau_{a} > t, \xi_t \in \mathcal{W}(\alpha) \} \cup \{ \tau_{a} = t, \xi_t \in \mathcal{W}(\pi/(2w)) \setminus \mathcal{W}(\alpha) \},
\]

for all \( B \) sufficiently large, using (A2) and the fact that by definition \( \{ \tilde{\tau}_{a,B} > t \} \subseteq \{ \|\xi_t\| > B \} \). We consider the two events in the disjoint union in (5.2) in turn. Let \( F_t := \sigma(\xi_0, \xi_1, \ldots, \xi_t) \). On \( \{ \tau_{a} > t \} \) we have \( \xi_t = \xi_t \) and \( \xi_{t+1} = \xi_t \). So by (5.1) there exists \( C' \in (0, \infty) \) such that, on \( \{ \tau_{a} > t \} \),

\[
\mathbb{E}[X_{t+1}^{2p_0} - X_t^{2p_0} \mid F_t] \leq -C' X_t^{2p_0 - 2}.
\]

On \( \{ \tau_{a} = t \} \), \( \mathbb{E}[X_{t+1}^{2p_0} - X_t^{2p_0} \mid F_t] = -X_t^{2p_0} \), so that on \( \{ \tilde{\tau}_{a,B} > t \} \cap \{ \tau_{a} = t \}, \mathbb{E}[X_{t+1}^{2p_0} - X_t^{2p_0} \mid F_t] \leq -B^2 X_t^{2p_0 - 2} \), since \( \tilde{\tau}_{a,B} > t \) implies that \( X_t^2 \geq B^2 \).
Thus, for some $C' \in (0, \infty)$, (5.3) holds on $\{\tilde{\tau}_{\alpha,B} > t\}$ for any $B \geq B_0$, say. We apply [1, Theorem 1] to obtain, for any $p \in [0, p_0)$, $B \geq B_0$, and $x \in W(\alpha)$,

$$\mathbb{E}[\tilde{r}_{\alpha,B}^p | \xi_0 = x] < \infty.$$  (5.4)

It remains to deduce the result for $\tau_\alpha$. On $\{\tau_\alpha \geq t\}$, $\tilde{\xi}_t = \xi_t$ and so by (3.13), on $\{\tau_\alpha \geq t\}$,

$$\|\xi_t\| \geq X_t \geq e^{1/w}\|\xi_t\|.$$  (5.5)

Recall that $\tilde{\tau}_{\alpha,B} \leq \tau_\alpha + 1$. On $\{\tilde{\tau}_{\alpha,B} \leq \tau_\alpha\}$, $\|\tilde{\xi}_{\tau_{\alpha,B}}\| \leq e^{-1/w}X_{\tilde{\tau}_{\alpha,B}} \leq e^{-1/w}B$ by (5.5). On the other hand, on $\{\tilde{\tau}_{\alpha,B} = \tau_\alpha + 1\}$, clearly $\tau_\alpha \leq \tilde{\tau}_{\alpha,B}$. Recalling the definition of $\tau_{\alpha,A}$ from (3.1), it follows that for all $A \geq B e^{-1/w}$, a.s., $\tau_{\alpha,A} \leq \tilde{\tau}_{\alpha,B}$. Then with (5.4) we obtain that for all $x \in W(\alpha)$ and all $A$ sufficiently large $\mathbb{E}[\tilde{r}_{\alpha,A}^p | \xi_0 = x] < \infty$.

Condition (A1) then extends the result to $\tau_\alpha$ by standard ‘irreducibility’ arguments. Indeed, (A1) implies that for random variables $K_0, K_1, K_2, \ldots$ with $\mathbb{P}[K_i \geq t] \leq e^{-ct}$, for some $c > 0$, $\tau_\alpha \leq \sum_{i=1}^{K_0}(\tau_i + K_i)$, where $\tau_1, \tau_2, \ldots$ are copies of $\tau_{\alpha,A}$; here $K_0$ represents the number of visits to $B_A(0)$ before leaving the wedge, and $K_1, K_2, \ldots$ are the durations of the successive visits. By (A2), on each exit from $B_A(0)$ into $W(\alpha)$, $\Xi$ is restricted to a finite number of states, and so $\mathbb{E}[\tau_{\alpha}^p]$ is uniformly bounded. Hence, for any $p < p_0$,

$$\mathbb{P}[\tau_\alpha \geq t] \leq \mathbb{P}[K_0 \geq C \log t] + \sum_{i=1}^{C \log t} \mathbb{P}[K_i \geq C \log t] + \sum_{i=1}^{C \log t} \mathbb{P}[\tau_i \geq t/(2C \log t)],$$

which is $O(t^{-p}(\log t)^{p+1})$, choosing $C < \infty$ large enough and using Boole’s and Markov’s inequalities. Thus $\mathbb{E}[\tau_{\alpha}^q] < \infty$ for any $q < p < p_0$.  

\[ 5.3 \quad \text{Proof of Theorem 2.4(i)} \]

**Lemma 5.2.** Suppose that (A2) holds, $\alpha \in (0, \pi]$, and for some $\sigma^2 \in (0, \infty)$, for $x \in W(\alpha)$, as $\|x\| \to \infty$,

$$\|\mu(x)\| = o(\|x\|^{-1}); \quad M_{12}(x) = o(1); \quad M_{11}(x) = \sigma^2 + o(1); \quad M_{22}(x) = \sigma^2 + o(1).$$  (5.6)

Then for any $w \in (0, \pi/(2\alpha))$ and any $\gamma \in (0, 1)$, there exist constants $A, C \in (0, \infty)$ for which for all $x \in W_A(\alpha)$,

$$\mathbb{E}[f_w(\xi_{t+1})^\gamma - f_w(\xi_t)^\gamma | \xi_t = x] \leq -C f_w(x)^{\gamma-2/w}. \quad (5.7)$$

**Proof.** Let $w \in (0, \pi/(2\alpha))$. For $x \in W(\alpha)$, (3.13) holds. Then by Lemma 3.3 with (5.6) we have that for $\gamma \in \mathbb{R}$,

$$\mathbb{E}[f_w(\xi_{t+1})^\gamma - f_w(\xi_t)^\gamma | \xi_t = x] = \frac{1}{2}(\gamma - 1)w^2 \sigma^2 f_w(x)^{\gamma-2}t^{2w-2}(1 + o(1)), \quad (5.8)$$

for all $x \in W(\alpha)$, as $\|x\| \to \infty$. It follows from (5.8) and (3.13) that for $\gamma \in (0, 1)$ and some $C \in (0, \infty)$, for $x \in W(\alpha)$ with $\|x\|$ sufficiently large (5.7) holds.  

**Proof of Theorem 2.4(i).** Let $w \in (0, \pi/(2\alpha))$. For $\gamma \in (0, 1)$, take $p_0 = \gamma w/2$. Then Lemma 5.2 says that for $x \in W(\alpha)$ with $\|x\|$ sufficiently large (5.1) holds for $\gamma \in (0, 1)$ and $w \in (0, \pi/(2\alpha))$. Then Lemma 5.1 implies that for any $x \in W(\alpha)$, $\mathbb{E}[r_{\alpha}^p | \xi_0 = x] < \infty$ for all $p \in [0, p_0)$. Since both $\gamma < 1$ and $w < \pi/(2\alpha)$ may be taken arbitrarily close to their upper bounds, we may choose any $p$ less than $\pi/(4\alpha)$.  

20
5.4 Non-existence of moments

Let $\alpha \in (0, \pi]$. Throughout this section we will take $w = \pi/(2\alpha)$. We will again be interested in $f_w(\xi_t)^\gamma$, $\gamma \in \mathbb{R}$, this time in the wedge $\mathcal{W}(\alpha)$. Due to difficulties with estimating the behaviour of $f_w(\xi_t)^\gamma$ near the boundary of the wedge $\mathcal{W}(\alpha)$, we cannot apply the non-existence theorems from [1]. We need a different approach.

A key step in this section is a good-probability lower-bound on the time taken to leave a wedge; this is Lemma 5.5 below. We use the Lyapunov function $\hat{v}$ apply the non-existence theorems from [1]. We need a different approach.

Let $\alpha \in (0, \pi]$, and $w = \pi/(2\alpha)$. Suppose that (A2) holds and for some $v \in (0, \infty)$, for $x \in \mathcal{W}(\alpha)$, as $\|x\| \to \infty$,

\[
\|\mu(x)\| = o(1); \quad M_{12}(x) = o(1); \quad M_{11}(x) \geq v + o(1); \quad M_{22}(x) \geq v + o(1). \tag{5.10}
\]

Then there exist $A, K \in (0, \infty)$ such that

\[
\mathbb{P}[\|\hat{v}(\xi_t)\| \leq K^{-1}w^{\alpha - 1} | \xi_t = x] \geq 0 \quad \text{for all} \quad x \in \mathcal{W}_A(\alpha) \setminus \mathcal{W}_K(\alpha).
\]

Proof. For $K > 0$, take $x \in \mathcal{W}(\alpha) \setminus \mathcal{W}_K(\alpha)$. By (5.9), $f_w(x) \leq K^{-1}r^{-w} - 1$ and hence $\cos(\omega x) \leq K^{-1}r^{-w} - 1$. To estimate the expected change in $f_w$ on a jump of $\mathcal{Z}$ started from $x$, we write $U(x) := \{y \in \mathcal{W}(\alpha) : f_w(y) \geq f_w(x)\}$ and $\hat{\Delta} := \hat{f}_w(\xi_{t+1}) - \hat{f}_w(\xi_t)$.

Since $\hat{f}_w(\xi_{t+1}) \geq 0$, we have $\mathbb{E}[\hat{\Delta} \mid \xi_t = x] \geq -f_w(\xi_t) \geq -K^{-1}r^{-w} - 1$, so

\[
\mathbb{E}[\hat{\Delta} | \xi_t = x] \geq \mathbb{E}[\hat{\Delta}_{1_{\{\xi_t+1 \in U(x)\}}} | \xi_t = x] = -K^{-1}r^{-w} - 1. \tag{5.11}
\]

Write $\Delta := f_w(\xi_{t+1}) - f_w(\xi_t)$. Then $\{\Delta \geq 0, \xi_t = x\} = \{\xi_{t+1} \in U(x), \xi_t = x\}$. For a random variable $X$ with $\mathbb{P}[|X| < m] = 1$, $\mathbb{E}[X1_{\{X \geq 0\}}] \geq \mathbb{E}[X] + m^{-1}\mathbb{E}[X^2]/2$; applying this inequality with $X = \Delta$ and using (3.8) gives, for some $C \in (0, \infty)$ and all $x \in \mathcal{W}(\alpha)$,

\[
\mathbb{E}[\Delta_{1_{\{\xi_{t+1} \in U(x)\}}} | \xi_t = x] \geq \mathbb{E}[\Delta_{1_{\{\xi_{t+1} \in U(x)\}}} | \xi_t = x] \geq \frac{1}{2}\mathbb{E}[f_w(\xi_{t+1}) - f_w(\xi_t) | \xi_t = x] + C(1 + \|x\|)^{1-w}\mathbb{E}[(f_w(\xi_{t+1}) - f_w(\xi_t))^2 | \xi_t = x].
\]

By (5.10), we obtain from (3.9) and (3.10) that there exists $C > 0$, not depending on $K$, such that, for all $x \in \mathcal{W}(\alpha)$ with $\|x\|$ large enough,

\[
\mathbb{E}[\Delta_{1_{\{\xi_{t+1} \in U(x)\}}} | \xi_t = x] \geq C\|x\|^{w-1}. \tag{5.12}
\]

It follows from Lemma 3.4 that we can replace $\Delta$ by $\hat{\Delta}$ in (5.12). Then the claimed result follows from (5.11) with (5.12), by taking $K$ large enough. \hfill \Box

Lemma 5.4. Suppose that (A2) holds and that for some $\sigma^2 \in (0, \infty)$, as $\|x\| \to \infty$, (2.4) holds. Let $\alpha \in (0, \pi]$. Then for $w = \pi/(2\alpha)$ and any $\gamma > 1$, there exists $A \in (0, \infty)$ for which, for all $x \in \mathcal{W}_A(\alpha)$,

\[
\mathbb{E}[\hat{f}_w(\xi_{t+1})^\gamma - \hat{f}_w(\xi_t)^\gamma | \xi_t = x] \geq 0. \tag{5.13}
\]
Proof. It suffices to take $\gamma \in (1, 2]$. Under the conditions of the lemma, Lemma 5.3 implies that for some $K$ the desired result holds for $x \in \mathcal{W}_A(\alpha) \setminus \mathcal{W}^K(\alpha)$. It remains to consider $x \in \mathcal{W}_A(\alpha) \cap \mathcal{W}^K(\alpha)$. Writing $\Delta = \hat{f}_w(\xi_{t+1}) - \hat{f}_w(\xi_t)$, we have that for $\xi_t = x$,

$$
\hat{f}_w(\xi_{t+1})^\gamma - \hat{f}_w(\xi_t)^\gamma = (\hat{f}_w(x) + \hat{\Delta})^\gamma - \hat{f}_w(x)^\gamma = f_w(x) \left[ \left( 1 + \frac{\hat{\Delta}}{\hat{f}_w(x)} \right)^\gamma - 1 \right]. \quad (5.14)
$$

To obtain a lower bound, we make use of the fact that for any $\gamma \in (1, 2]$ and $L \in (0, \infty)$,

$$(1 + x)^\gamma \geq 1 + \gamma x + \frac{1}{2} (1 + L)^{\gamma-2} \gamma (\gamma - 1) x^2 \quad (5.15)$$

for $x \in [-1, L]$. To apply (5.15) in (5.14) with $x = \hat{\Delta}/\hat{f}_w(x)$ we need $-\hat{f}_w(x) \leq \hat{\Delta} \leq L\hat{f}_w(x)$. The first inequality here is automatically satisfied since $\hat{f}_w(\xi_{t+1}) \geq 0$ a.s. For the second inequality, (3.8) and (5.9) show that for $x \in \mathcal{W}^K(\alpha)$, on $\{\xi_t = x\}$, $\|\Delta\| \leq C\|x\|^{\gamma-1} \leq CK\hat{f}_w(x) = CK\hat{f}_w(x)$. So taking $L = CK$ we can indeed apply (5.15) in (5.14) to obtain, for some $A, C \in (0, \infty)$, for any $x \in \mathcal{W}_A(\alpha) \cap \mathcal{W}^K(\alpha)$, given $\xi_t = x$,

$$
\hat{f}_w(\xi_{t+1})^\gamma - \hat{f}_w(\xi_t)^\gamma \geq \gamma f_w(x)^{\gamma-1} \hat{\Delta} + C f_w(x)^{\gamma-2} \hat{\Delta}^2.
$$

The right-hand side of the last display is increasing in $\Delta$, and so by Lemma 3.4 we can replace $\Delta$ by $\Delta$ and then take expectations to obtain

$$
\mathbb{E}[\hat{f}_w(\xi_{t+1})^\gamma - \hat{f}_w(\xi_t)^\gamma \mid \xi_t = x] \geq \gamma f_w(x)^{\gamma-1} \mathbb{E}[f_w(\xi_{t+1}) - f_w(\xi_t) \mid \xi_t = x] + C f_w(x)^{\gamma-2} \mathbb{E}[(f_w(\xi_{t+1}) - f_w(\xi_t))^2 \mid \xi_t = x],
$$

for some $C > 0$ and any $x \in \mathcal{W}_A(\alpha) \cap \mathcal{W}^K(\alpha)$. Now from Lemma 3.1 and the conditions on $\mu(x)$ and $\mathbb{M}(x)$ it follows that, for some $C > 0$, as $\|x\| \to \infty$,

$$
\mathbb{E}[\hat{f}_w(\xi_{t+1})^\gamma - \hat{f}_w(\xi_t)^\gamma \mid \xi_t = x] \geq f_w(x)^{\gamma-1} \left[ C f_w(x)^{-1} r^{2w-2} + o(r^{w-2}) \right],
$$

for any $x \in \mathcal{W}_A(\alpha) \cap \mathcal{W}^K(\alpha)$. Then the result follows since $f_w(x)^{-1} \geq r^{-w}$. \qed

5.5 Key estimate

Lemma 5.5. Suppose that (A1) and (A2) hold, and that for some $\sigma^2 \in (0, \infty)$, (2.4) holds. Let $\alpha \in (0, \pi)$ and $w = \pi/(2\alpha)$. There exist $A \in (0, \infty)$ and $\varepsilon_1, \varepsilon_2 > 0$ such that for all $x \in \mathcal{W}(\alpha)$ with $\|x\| > A$, $\mathbb{P}[\tau_{\alpha, A} > \varepsilon_1 \|x\|^2 \mid \xi_0 = x] \geq \varepsilon_2 \cos(\varphi)w$.

Our proof makes repeated use of the processes $(Y_t(x))_{t \in \mathbb{Z}^+}$ defined for $x \in \mathbb{Z}^2$ by

$$
Y_t(x) := \|\xi_t - x\|. \quad (5.16)
$$

By the triangle inequality and (A2), $|Y_{t+1}(x) - Y_t(x)| \leq \|\xi_{t+1} - \xi_t\| \leq b$, a.s.; the next lemma gives more on the increments of $Y_t(x)$. For $x \in \mathbb{Z}^2$ and $C \in (1, \infty)$ write

$$
S(x; C) := \{y \in \mathbb{Z}^2 : C^{-1} \|x\| \leq \|y\| \leq C \|x\|\}; \quad U(x; C) := \{y \in \mathbb{Z}^2 : \|y - x\| \geq C^{-1} \|x\|\}.
$$

Lemma 5.6. Suppose that (A1) and (A2) hold, and that for some $\sigma^2 \in (0, \infty)$, (2.4) holds. Then for any $x \in \mathbb{Z}^2$ and any $C \in (1, \infty)$, as $\|x\| \to \infty$,

$$
\sup_{y \in S(x; C)} \mathbb{E}[|Y_{t+1}(x)^2 - Y_t(x)^2| \mid \xi_t = y] - 2\sigma^2 = o(1), \quad (5.17)
$$

22
Taylor's theorem applied to the term in square brackets on the right of (5.21) yields

$$\sup_{y \in S(x; C) \cap U(x; C)} \left| \mathbb{E}[Y_{\ell+1}(x) - Y_\ell(x) \mid \xi_\ell = y] - \frac{1}{2} \sigma^2 \|y - x\|^2 \right| = o(\|x\|^{-1}),$$  \hspace{1cm} (5.18)

$$\sup_{y \in S(x; C) \cap U(x; C)} \left| \mathbb{E}[(Y_{\ell+1}(x) - Y_\ell(x))^2 \mid \xi_\ell = y] - \sigma^2 \right| = o(1).$$  \hspace{1cm} (5.19)

**Proof.** Conditional on $\xi_\ell = y \in \mathbb{Z}^2$ we have that

$$\mathcal{L}(Y_{\ell+1}(x) \mid \xi_\ell = y) = \mathcal{L}(\|y - x\|^2 + \|\theta(y)\|^2 + 2(y - x) \cdot \theta(y))^{1/2}).$$  \hspace{1cm} (5.20)

Then (5.20) with (2.4) yields

$$\mathbb{E}[Y_{\ell+1}(x)^2 - Y_\ell(x)^2 \mid \xi_\ell = y] = \mathbb{E}[\|\theta(y)\|^2] + 2\mathbb{E}[(y - x) \cdot \theta(y)]$$

$$= 2\sigma^2 + o(1) + o(\|y - x\| \|y\|^{-1}) = 2\sigma^2 + o(1),$$

for all $y$ with $C^{-1}\|x\| \leq \|y\| \leq C\|x\|$. This proves (5.17). Similarly, by (5.20),

$$\mathbb{E}[Y_{\ell+1}(x) - Y_\ell(x) \mid \xi_\ell = y] = Y_\ell(x) \mathbb{E}\left[ \left( 1 + \frac{\|\theta(y)\|^2 + 2(y - x) \cdot \theta(y)}{\|y - x\|^2} \right)^{1/2} - 1 \right].$$  \hspace{1cm} (5.21)

Taylor’s theorem applied to the term in square brackets on the right of (5.21) yields

$$\frac{1}{2} \frac{\|\theta(y)\|^2 + 2(y - x) \cdot \theta(y)}{\|y - x\|^2} - \frac{1}{8} \frac{4((y - x) \cdot \theta(y))^2}{\|y - x\|^4} + O(\|x\|^{-3}),$$

using (A2), provided that $C^{-1}\|x\| \leq \|y - x\|$ and $C^{-1}\|x\| \leq \|y\| \leq C\|x\|$. Taking expectations of this last expression and using (2.4) and (5.21), we obtain (5.18). Finally, given $\xi_\ell = y$, $(Y_{\ell+1}(x) - Y_\ell(x))^2 = (Y_{\ell+1}(x)^2 - Y_\ell(x)^2) - 2(y - x) \cdot (Y_{\ell+1}(x) - Y_\ell(x))$, so from (5.18) and (5.17) we obtain (5.19).

**Proof of Lemma 5.5.** Suppose that $\xi_0 = x \in \mathcal{W}(\alpha)$. Fix $\alpha' \in (0, \alpha)$, which we will take close to $\alpha$. First suppose that $x \in \mathcal{W}(\alpha')$. Note that the shortest distance from $x \in \mathcal{W}(\alpha)$ to the wedge boundary $\partial \mathcal{W}(\alpha)$ is at least $\|x\| \sin(\alpha - |\varphi|)$, and that for all $x \in \mathcal{W}(\alpha')$, $\varphi \in (-\alpha', \alpha')$ so this distance is at least $\varepsilon_0 \|x\|$, where $\varepsilon_0 := \sin(\alpha - \alpha') > 0$.

Suppose that $y \in B_{\varepsilon_0\|x\|/2}(x) \subset \mathcal{W}(\alpha)$. For $y \in B_{\varepsilon_0\|x\|/2}(x)$, we have

$$\|y - x\| \leq (\varepsilon_0/2)\|x\|, \quad \|y\| \leq (1 + (\varepsilon_0/2))\|x\|, \quad \text{and} \quad \|y\| \geq (1 - (\varepsilon_0/2))\|x\|. \hspace{1cm} (5.22)$$

It then follows from (5.17) and (5.22) that for $y \in B_{\varepsilon_0\|x\|/2}(x)$,

$$\mathbb{E}[Y_{\ell+1}(x)^2 - Y_\ell(x)^2 \mid \xi_\ell = y] = 2\sigma^2 + o(1),$$  \hspace{1cm} (5.23)

as $\|x\| \to \infty$. For the rest of this proof, let $\kappa = \min\{t \in \mathbb{Z}^+ : \|\xi_t - x\| \geq \varepsilon_0\|x\|/2\}$, the first exit time of $\Xi$ from $B_{\varepsilon_0\|x\|/2}(x)$. It follows from (5.23) that for all $x \in \mathcal{W}(\alpha')$ with $\|x\|$ large enough, $Y_{\ell+1}(x)^2$ is a nonnegative submartingale with respect to the natural filtration for $\Xi$, and there exists $C \in (0, \infty)$ such that for all $x \in \mathcal{W}(\alpha')$ with $\|x\|$ sufficiently large and for all $t \in \mathbb{Z}^+$, $\mathbb{E}[Y_{\ell+1}(x)^2 \mid \xi_\ell = x] \leq Ct \land \kappa \leq Ct$.

Doob’s submartingale inequality implies that there exists $C \in (0, \infty)$ such that for any $x \in \mathcal{W}(\alpha')$ with $\|x\|$ sufficiently large, any $t \in \mathbb{Z}^+$, and any $x > 0$, $\mathbb{P}[\max_{0 \leq s \leq t} Y_{s+\kappa}(x)^2 \geq x \mid \xi_\ell = x] \leq \varepsilon_0\|x\|/2$. So in time $t = x/(2C)$, there is probability at least $1/2$ that $\max_{0 \leq s \leq t} Y_{s+\kappa}(x) \leq x^{1/2}$. Noting that $Y_{\kappa}(x) \geq \varepsilon_0\|x\|/2$ a.s., and taking $x = \varepsilon_0^2\|x\|^2/9$, we conclude that

$$\mathbb{P}\left[ \max_{0 \leq s \leq \varepsilon_0^2\|x\|^2/18C} \|\xi_s - x\| \leq \varepsilon_0\|x\|/3 \mid \xi_0 = x \right] \geq 1/2.$$
The event in the last displayed probability implies that $\Xi$ remains in $B_{e\Vert x\Vert/2}(x) \subset \mathcal{W}(\alpha)$ till time $\varepsilon_0^2\Vert x\Vert^2/(18C)$. So, for any $x \in \mathcal{W}(\alpha')$ with $\Vert x\Vert$ sufficiently large,

$$
P \left[ \tau_{\alpha,A} \geq \frac{\varepsilon_0^2}{18C} \Vert x\Vert^2 \bigg| \xi_0 = x \right] \geq 1/2.
$$

(5.24)

This yields the statement in the lemma for $x \in \mathcal{W}(\alpha')$, for any $\alpha' \in (0, \alpha)$.

Now we need to deal with the case $x \in \mathcal{W}(\alpha) \setminus \mathcal{W}(\alpha')$. We take $\alpha' < \alpha$ but close to $\alpha$, so that $\varepsilon_0 = \sin(\alpha - \alpha')$ is small. Suppose that $x \in \mathcal{W}(\alpha) \setminus \mathcal{W}(\alpha')$, and, without loss of generality, that $\varphi > 0$; then $\varphi \in [\alpha', \alpha)$. Set

$$
R := R(\alpha; x) := \begin{cases} 1 & \text{if } \alpha \geq \pi/2 \\ 1 \land [\tan(\alpha)(\cos(\alpha - \varphi))] & \text{if } \alpha \in (0, \pi/2) \end{cases},
$$

and then define $c(x) := e_\alpha(\alpha)\Vert x\Vert \cos(\alpha - \varphi) - R(\alpha; x)e_\perp(\alpha)\Vert x\Vert$; if $R < 1$, $c(x) = e_1\Vert x\Vert \cos(\alpha - \varphi) \sec \alpha$ lies on the principal axis of the wedge. Note

$$
\Vert c(x)\Vert = \Vert x\Vert \left( R^2 + \cos^2(\alpha - \varphi) \right)^{1/2},
$$

(5.25)

and also $x - c(x) = (R - \sin(\alpha - \varphi))\Vert x\Vert e_\perp(\alpha)$, so that

$$
\Vert x - c(x)\Vert = (R - \sin(\alpha - \varphi))\Vert x\Vert \geq \varepsilon_1\Vert x\Vert,
$$

(5.26)

for some $\varepsilon_1 > 0$ and all $x \in \mathcal{W}(\alpha) \setminus \mathcal{W}(\alpha')$ provided that $\alpha'$ is close enough to $\alpha$. Also from (5.25) we have that for some $\varepsilon_2 > 0$ and all $x \in \mathcal{W}(\alpha) \setminus \mathcal{W}(\alpha')$,

$$
\varepsilon_2\Vert x\Vert \leq \Vert c(x)\Vert \leq \sqrt{2}\Vert x\Vert.
$$

(5.27)

Consider the concentric disks $D_1(x) := B_{R\Vert x\Vert/2}(c(x))$ and $D_2(x) := B_{R\Vert x\Vert}(c(x))$. If $R = 1$, the shortest distance of $c(x)$ from the ray from $0$ in the $e_\alpha(\alpha')$ direction is

$$
\Vert x\Vert \cos(\alpha - \alpha') - \Vert x\Vert \sin(\alpha - \alpha') \cos(\alpha - \varphi) \geq (1 - \varepsilon_0)\Vert x\Vert \cos(\alpha - \alpha'),
$$

for all $x \in \mathcal{W}(\alpha) \setminus \mathcal{W}(\alpha')$. If $R < 1$, the corresponding distance is $\Vert x\Vert \cos(\alpha - \varphi) \sec \alpha \sin \alpha'$. In either case, choosing $\alpha'$ close enough to $\alpha$, it follows that $D_1(x) \subset \mathcal{W}(\alpha')$ for all $x \in \mathcal{W}(\alpha) \setminus \mathcal{W}(\alpha')$. Moreover, for $\varepsilon_0$ small enough, for any $y \in D_2(x)$, by (5.25),

$$
\Vert y\Vert \geq \Vert c(x)\Vert - R\Vert x\Vert \geq \left( (R^2 + 1 - \varepsilon_0^2)^{1/2} - R \right) \Vert x\Vert \geq \varepsilon_0\Vert x\Vert.
$$

(5.28)

We now aim to show that there exists $\varepsilon' > 0$ such that for all $x \in \mathcal{W}(\alpha) \setminus \mathcal{W}(\alpha')$ with $\Vert x\Vert$ sufficiently large,

$$
p(x) := P \left[ \Xi \text{ visits } D_1(x) \text{ before } \mathbb{R}^2 \setminus D_2(x) \bigg| \xi_0 = x \right] \geq \varepsilon' \cos(\omega\varphi).
$$

(5.29)

The geometrical argument leading up to (5.28) with (A2) implies that if the event in (5.29) occurs, $\Xi$ visits a region of $\mathcal{W}(\alpha')$ at distance at least $\varepsilon_0\Vert x\Vert$ from $0$ before leaving $\mathcal{W}(\alpha)$. Hence given (5.29), (5.24) yields the statement in the lemma in this case also.

Thus it remains to prove (5.29). With the notation defined at (5.16), we now consider $Y_1(c(x)) = \Vert \xi_t - c(x)\Vert$ for $\xi_t$ in the annulus $D_2(x) \setminus D_1(x)$. For any $y \in D_2(x) \setminus D_1(x)$ we have $R\Vert x\Vert/2 \leq \Vert y - c(x)\Vert \leq R\Vert x\Vert$, so that $\Vert y\Vert \leq \Vert x\Vert + \Vert c(x)\Vert$. This together with
(5.27) and (5.28) implies that for \(\alpha'\) close enough to \(\alpha\) there exist \(C_1, C_2 \in (0, \infty)\) such that for any \(x \in W(\alpha) \setminus W(\alpha')\) and any \(y \in D_2(x) \setminus D_1(x),\)

\[
C_1\|x\| \geq \|y\| \geq C_2\|x\|, \quad \text{and} \quad \|y - c(x)\| \geq C_2\|x\|. \tag{5.30}
\]

Hence by (5.30) and (5.27), the estimates (5.18) and (5.19) are valid for \(y \in D_2(x) \setminus D_1(x),\) as \(\|x\| \to \infty.\) Thus we have that there exists \(\delta > 0\) such that for \(x \in W(\alpha) \setminus W(\alpha')\) with \(\|x\|\) large enough and all \(y \in D_2(x) \setminus D_1(x),\)

\[
\begin{align*}
\mathbb{E}[Y_{t+1}(c(x)) - Y_t(c(x)) | \xi_t = y] &= O(\|x\|^{-1}), \tag{5.31} \\
\mathbb{E}[(Y_{t+1}(c(x)) - Y_t(c(x)))^2 | \xi_t = y] &> \delta > 0. \tag{5.32}
\end{align*}
\]

For \(C \in (0, \infty)\) set \(Z_t := \exp \{ C (R(\alpha; x) - \|x\|^{-1}Y_t(c(x))) \};\) then by (5.26), \(Z_0 = \exp\{C \sin(\alpha - \varphi)\}.\) For \(t \in \mathbb{Z}^+\) and \(y \in \mathbb{Z}^2,\)

\[
\mathbb{E}[Z_{t+1} - Z_t | \xi_t = y] = \exp \left\{ C \left( R - \frac{\|y - c(x)\|}{\|x\|} \right) \right\} \mathbb{E} \left[ \exp \left\{ - \frac{C}{\|x\|} (Y_{t+1}(c(x)) - Y_t(c(x))) \right\} - 1 \mid \xi_t = y \right].
\]

Since there exist positive constants \(C_1, C_2\) such that \(e^{-x} - 1 \geq -x + C_1 x^2\) for all \(x\) with \(|x| < C_2\), using the fact that \(Y_t(c(x))\) has uniformly bounded increments we obtain that for any \(x \in W(\alpha) \setminus W(\alpha')\) and any \(y \in D_2(x) \setminus D_1(x),\)

\[
\begin{align*}
\mathbb{E} \left[ \exp \left\{ - \frac{C}{\|x\|} (Y_{t+1}(c(x)) - Y_t(c(x))) \right\} - 1 \mid \xi_t = y \right] &\geq \frac{C}{\|x\|} \mathbb{E} \left[ -(Y_{t+1}(c(x)) - Y_t(c(x))) + C_1 \frac{C}{\|x\|} (Y_{t+1}(c(x)) - Y_t(c(x)))^2 \mid \xi_t = y \right].
\end{align*}
\]

So by (5.31), (5.32) we may take \(C\) large enough such that for \(\xi_0 = x \in W(\alpha) \setminus W(\alpha'),\)

\[
\mathbb{E}[Z_{t+1} - Z_t | \xi_t = y] \geq 0, \tag{5.33}
\]

for all \(y \in D_2(x) \setminus D_1(x)\) with \(\|x\|\) large enough, and all \(t \in \mathbb{Z}^+.\)

Now to estimate \(p(x)\) as in (5.29), we make the sets \(D_1(x)\) and \(\mathbb{R}^2 \setminus D_2(x)\) absorbing. Then (using (A2)) \(Z_t\) is bounded for this modified random walk, and (using (A1)) \(Z_t\) leaves \(D_2(x) \setminus D_1(x)\) in almost surely finite time. Thus as \(t \to \infty,\) \(Z_t\) converges almost surely and in \(L^1\) to some limit \(Z_{\infty}\) and \(\mathbb{E}[Z_{\infty} | \xi_0 = x] \leq p(x) \exp\{CR/2\} + (1 - p(x)),\)

while by (5.33) we also have that \(\mathbb{E}[Z_{\infty} | \xi_0 = x] \geq \mathbb{E}[Z_0] = \exp\{C \sin(\alpha - \varphi)\}.\)

Hence there exists \(C \in (0, \infty)\) such that for all \(x \in W(\alpha) \setminus W(\alpha')\) with \(\|x\|\) large enough

\[
p(x) \geq \frac{\exp\{C \sin(\alpha - \varphi)\} - 1}{\exp\{CR/2\} - 1} \geq \frac{C}{e^{CR/2} - 1} \sin(\alpha - \varphi).
\]

Now for \(x \in W(\alpha) \setminus W(\alpha')\) we have that \(\alpha - \varphi < \alpha - \alpha',\) where \(\alpha - \alpha'\) is small. Since, for \(\alpha > 0, \frac{\sin(\alpha')}{\sin(x)} \to a \) as \(x \to 0,\) there exists some \(\epsilon' > 0\) such that \(\frac{C}{e^{CR/2} - 1} \sin(\alpha - \varphi) \geq \epsilon' \sin(w(\alpha - \varphi)) = \epsilon' \cos(w \varphi).\) This proves (5.29). \(\square\)
5.6 Proof of Theorem 2.4(ii)

Proof of Theorem 2.4(ii). Let $\alpha \in (0, \pi]$ and $w = \pi/(2\alpha)$. We first show that for $A \in (0, \infty)$ sufficiently large, any $\varepsilon > 0$, and any $x \in W_A(\alpha)$, $\mathbb{E}[\tau_{\alpha}^{(w/2)+\varepsilon} | \xi_0 = x] = \infty$. Write $\tau := \tau_{\alpha,A}$. Let $x \in W_A(\alpha)$ be such that $f_w(x) > A^w$. Suppose, for the purpose of deriving a contradiction, that for some $\varepsilon > 0$, $\mathbb{E}[\tau^{(w/2)+\varepsilon} | \xi_0 = x] < \infty$. Let $\Xi = (\xi_t)_{t \in \mathbb{Z}^+}$ be an independent copy of $\Xi$, and let $\tau'$ be the corresponding independent copy of $\tau$. Then for any $t \in \mathbb{N}$, conditioning on $\xi_t$ and using the Markov property, $\mathbb{E}[\tau^{(w/2)+\varepsilon} | \xi_0 = x] \geq \mathbb{E}[\mathbb{E}[(t + \tau')^{(w/2)+\varepsilon} | \xi'_t = \xi_t] \mathbf{1}_{\{\tau > t\}} | \xi_0 = x]$. By Lemma 5.5, for $A$ large enough,

$$
\mathbb{E}[\tau^{(w/2)+\varepsilon} | \xi_0 = x] \geq \varepsilon_2 \mathbb{E}[(t + \varepsilon_1 \|\xi_t\|^2)^{(w/2)+\varepsilon} \cos(w\varphi(\xi_t)) \mathbf{1}_{\{\tau > t\}} | \xi_0 = x] \\
\geq C\mathbb{E}[(\hat{f}_w(\xi_{t\lor \tau}))^{1+(2/w)\varepsilon} | \xi_0 = x] - A^{w+2\varepsilon},
$$

for some $C \in (0, 1)$, any $t \in \mathbb{N}$, using the fact that $\hat{f}_w(\xi_{t\lor \tau}) \leq A^w$ a.s. Thus the process $(\hat{f}_w(\xi_{t\lor \tau}))^{1+\varepsilon'}$ is uniformly integrable, and, as $t \to \infty$, $\mathbb{E}[(\hat{f}_w(\xi_{t\lor \tau}))^{1+\varepsilon'} | \xi_0 = x] \to \mathbb{E}[(\hat{f}_w(\xi_{\tau}))^{1+\varepsilon'} | \xi_0 = x] \leq A^{w(1+\varepsilon')}$.

However, by the submartingale property (5.13), for $A$ large enough, $\mathbb{E}[(\hat{f}_w(\xi_{t\lor \tau}))^{1+\varepsilon'} | \xi_0 = x] \geq (\hat{f}_w(x))^{1+\varepsilon'} > A^{w(1+\varepsilon')}$ for all $t \in \mathbb{N}$. Thus we have the desired contradiction, and $\mathbb{E}[\tau^{(w/2)+\varepsilon} | \xi_0 = x] = \infty$ for any $x \in W_A(\alpha)$ with $f_w(x) > A^w$. Since $\tau_{\alpha} \geq \tau$, $\mathbb{E}[\tau_{\alpha}^{(w/2)+\varepsilon} | \xi_0 = x] = \infty$ for any $x \in W_A(\alpha)$ with $f_w(x) > A^w$. Lemma 4.9 extends the conclusion to any $x \in W(\alpha)$ with $\|x\|$ large enough. \hfill \Box
