Abstract

Aim Adolescents’ sleep duration has decreased over the past century; this is mainly caused by problems with falling asleep. Short sleep duration, poor sleep quality, and later bedtimes, in addition to difficulties in falling asleep, are further associated with adolescents’ increased food intake, poor diet quality, and excess body weight. Obesity has become a major health worldwide problem, with increasing prevalence among several age groups. In addition, higher body mass index is one of the most consistently reported correlates of short sleep duration. The aim of this study was to study if short sleep duration, connected with problems falling asleep, is associated with obesity and weight gain among Norwegian adolescents.

Subject and methods This is a cross-sectional study using data from the Young-HUNT3 cohort study, which comprises the adolescent part of HUNT3. Young-HUNT3 includes data on 8217 participants aged 13 to 20 years old. Cluster analysis were used to categorize patterns of similarities in food consumption. Bivariate analyses were conducted to explore associations between difficulties in falling asleep and unhealthy food patterns.

Results The analyses found statistically significant differences (< 0.001) between adolescents having an unhealthy food pattern, higher BMIs, and more difficulties with falling asleep than adolescents with a healthy food pattern.

Conclusion This study shows that an unhealthy food pattern is associated with shorter sleep duration among Norwegian adolescents. Health promotion educational interventions focusing on disseminating knowledge to parents and adolescents about unhealthy food intake and other risk factors related to insufficient sleep ought to be developed.

Keywords Short sleep duration · Food patterns · Falling asleep · Adolescents

Background

A good night’s sleep is critical for people’s health, and is an important part in the natural process of restoration (Jerath et al. 2014). There is accumulating evidence that shorter sleep duration is becoming a pervasive problem in today’s society (Hasler et al. 2004). Reduction of sleep duration may results in metabolic alterations, including glucose intolerance (Spiegel et al. 2014).
confirming that sleep problems, especially among adolescents, need attention. Studies show that reduced sleep is associated with increased food intake among young males (Brondel et al. 2010). Furthermore, some adolescents also tend to have interest in more evening-type activities (Carskadon et al. 1993), challenging their “biological clock”. Staying awake in the evenings, especially on weekend nights, makes it even harder to fall asleep on school nights (Owens and Group 2014).

The sleep duration of adolescents has decreased, but the decreased sleep duration also increases with higher age (Matricciani and Olds 2012). The National Sleep Foundation has assessed that adolescents need 9 h of sleep. Less than 8 h of sleep on school nights is considered an inadequate sleep length (Gradisar et al. 2013). Several studies have shown that inadequate sleep duration (< 8 h/day) is related to numerous harmful health outcomes such as hypertension, diabetes, and risk of suicide in adults (Ayas et al. 2003; Cohen et al. 2009; Fitzgerald et al. 2011; Knutson and Van Cauter 2008; Kripke et al. 2002). Other studies of children and adolescents have shown associations between short sleep duration and low meal frequency (Stroebele et al. 2013), high intake of snacks and soft drinks (McKnight-Eily et al. 2011), and low intake of fruits and vegetables (Garaulet et al. 2011). A study of Norwegian adolescents has shown that sleep duration was associated with several health-risk behaviors, such as current smoking or snuffing, irregular meal patterns and intake of sweets, and poor academic achievement (Stea et al. 2014). Short sleep duration is also found to be associated with obesity in children and young adults (Nielsen et al. 2011).

Obesity has become a widespread, worldwide health problem, contributing to a major negative impact on human health (Lind et al. 2016). The massive increase in obesity observed over the previous 3 decades could involve a numerous of reasons, but it is mostly related to an increase in food consumption and a decrease in physical activity (Ogden et al. 2014). Dietary patterns characterized by high meat consumption are found to be associated with unhealthy life styles and depression symptoms in adults (Gregório et al. 2017). Unhealthy eating behaviors among adolescents has also been related to stressful situations such as low levels of social support and inadequate coping skill (Martyn-Nemeth et al. 2009).

Based on the presented background, the aim of this study is to investigate associations between BMI, unhealthy diets, and difficulties in falling asleep among adolescents, using epidemiological data from the Norwegian Young-HUNT3 study.

Methods

The HUNT Study in Norway includes a unique database of self-reported and clinical data on personal and family medical histories connected to health and lifestyle (Krokstad et al. 2013). The Young-HUNT3 population contained 8217 teenagers from the age of 13 to 20 years old. We have used descriptive statistics to explore the associations.

Data collection

In the Young-HUNT surveys, students in junior high and high school first received written information about the purpose of the study. For all junior high school students, a written consent from a parent or guardian was also required. This consent was distributed along with the written information, which was returned and signed at the school before being passed on to the HUNT Research Center. The students signed a written consent to participate in school before they were included in the study. Students who were absent on the day of the self-reported questionnaire session had to sign their consent when they participated in the clinical part of the survey. Youths absent from school got both the questionnaires and written consent by post to their home address; these were completed and returned by post to the HUNT Research Center.

Demographic cohort

Nord-Trøndelag County is situated in the middle of Norway and has a population size of about 130,000 inhabitants. The county is mostly rural with no large cities, but several small towns. The county is representative of Norway with regard to geography, economy, industry, sources of income, age distribution, morbidity, and mortality. From 2017 Nord-Trøndelag County merged with Sør-Trøndelag County and became Trøndelag County.

Measurements

The data in this study consist of measurements assessing BMI, diet, and sleeping habits. Sleeping habits were assessed using questions created by the Norwegian Institute of Public Health and especially for Young-HUNT, “During the last month have you: had difficulty falling asleep in the evening?”. The question is also used in other studies assessing sleep habits (Sivertsen et al. 2015). Eating habits were measured using seven items of the validated Eating Attitudes Test (EAT) (Garner and Garfinkel 1979), while food consumption was collected by asking how often the participants normally ate or drank different kinds of food and drinks (e.g., fruits, vegetables, boiled potatoes, oily fish, whole-grain bread, white and semi-grain bread, chocolate/candy, pasta, sausages, water, sugar-free and sugary soft drinks, whole milk, and juice).

Statistical analyses

Data were analyzed using IBM SPSS Statistics (version 22). We used descriptive statistics to describe food patterns and chi-square statistics to explore food group consumption.
frequency variations (André et al. 2017). A p value of < 0.05 was set as the cut-off point for statistical significance, but the phi coefficient from the chi-square statistics was also checked to evaluate the strength of the associations. Food patterns were identified with the use of cluster analysis (André et al. 2017). K-means cluster analysis is appropriate for data with big sample dimensions (André et al. 2017). This analysis generates clusters with comparable characteristics (Gregório et al. 2017) where the respondents are categorized into distinct clusters (André et al. 2017). Food variables were re-coded into continuous variables by calculating the normal intake for 1 week (André et al. 2017). We then checked for and excluded extremes or outliers. Therefore, the continuous variables were consistent before consecutive rounds of K-means cluster analysis were used to confirm that the clusters were not predisposed by food groups with exact occurrence (Magidson and Vermunt 2002). The final model met the assumptions of K-means clustering.

**Ethical issues**

The information pamphlets for the Young-HUNT3 study were developed in cooperation with the Data Inspectorate of Norway, the Health Directorate of Norway, and the Regional Committees for Medical and Health Research Ethics. The written consents from both the participants and their guardians were stored in the HUNT databank. Both HUNT and the Regional Committees for Medical and Health Research Ethics (REK, 2015/1211) have accepted this study.

**Results**

Table 1 presents the attendance rates for the Young-HUNT3 Survey, showing an attendance rate for both questionnaire and clinical data of 73.7% (n = 7716).

Table 2 presents the descriptive data of BMI and how often the adolescents found it difficult to fall asleep in the evening.

**Food consumption**

More than half of the adolescents in the survey reported eating potato chips (53.2%) and candy/chocolate (64.1%) every week. Only approximately one third ate whole-grain bread several times a day, and almost half of the sample (47.3%) consumed fish (salmon, trout, and mackerel) less than every week. Daily, a

**Fig. 1** Cluster centers describe the average value for each variable within each cluster and reflect the characteristics of the typical case for each cluster.
significantly greater proportion of boys than girls consumed oily fish, potato chips, candy, chocolate, and cheese. A higher number of girls than boys consumed fruit and vegetables daily.

**Cluster analysis**

The cluster analysis resulted in two clusters based on similarities in reported food consumption among the adolescents. Cluster 1 consisted of adolescents with an unhealthy food pattern reporting a larger consumption of chocolate/candy, pasta, sausages, sugar-free and sugary soft drinks, whole milk, juice, and white and semi-grain breads than adolescents in cluster 2, which had a healthy food pattern involving higher consumption of fruits, vegetables, boiled potatoes, oily fish, whole-grain bread, and water.

**Lifestyle characteristics**

Table 3 presents the results from the bi-variate analyses exploring differences between sleeping habits and food patterns (healthy cluster 2 versus unhealthy cluster 1), and between BMI and the food patterns. These analyses show statistically significant associations between difficulties in falling asleep and adolescents with an unhealthy food pattern (cluster 1), and statistically significant associations between BMI and food patterns. There are fewer adolescents with an unhealthy food pattern (cluster 1) and low BMI, and there are more adolescents with an unhealthy food pattern (cluster 1) and high BMI.

**Discussion**

The aim of this study was to investigate the associations between BMI, food patterns, and difficulties in falling asleep among Norwegian adolescents. Our study confirmed findings from other studies (Gregório et al. 2017; Lien et al. 2001) showing that higher BMI is associated with eating unhealthy food. There may be, however, many reasons why adolescents eat unhealthily. Other studies have shown that poor eating habits also are linked to larger food intake, reduction in exercise (Lind et al. 2016), feeling stressed (Martyn-Nemeth et al. 2009), too much TV viewing, and inactivity (Pearson et al. 2014). However, other studies have found that adolescents who are living alone with little or no peer support have an unhealthier diet (Fitzgerald et al. 2013).

Findings in this study confirmed the findings from another study (Brondel et al. 2010), showing statistically significant associations between problems with falling asleep among adolescents and unhealthy food patterns. Other studies have shown associations between short sleep duration, low meal frequency (Stroebele et al. 2013), and high intake of snacks and soft drinks (McKnight-Eily et al. 2011), both food choices that are characteristics of an unhealthy diet.

Our bi-variate analyses detected that adolescents having difficulties with falling asleep also had an unhealthy food pattern and a higher BMI. To target adolescents’ food intake, prevention programs designed to support health dietary choices are warranted (Fitzgerald et al. 2013). Furthermore,
short sleep durations due to difficulties falling asleep are both a health and an educational advancement risk for adolescents (Ayas et al. 2003; Fitzgerald et al. 2011; Knutson and Van Cauter 2008; Kripke et al. 2002; Stea et al. 2014).

Previously, when giving adolescents lifestyle recommendations, the focus has been on food consumption and exercise; here, we show the importance of good sleep patterns, and point to the importance of including factors such as sleep quality and duration in such recommendations (Chaput 2014). Adolescents’ overall health may be at risk by not getting an adequate amount of sleep. More attention towards innovative solutions to reduce poor sleeping habits are therefore needed (Chaput 2014). Health personnel, e.g., pediatricians (Owens and Group 2014) or school health nurses, have the potential to advocate for educational, administrative, and health policies that promote healthy sleep habits in adolescents. Health education classes and school-based interventions may also be valuable strategies to prevent unhealthy eating and to advocate better sleep patterns. To register patterns and changes among adolescents in relation to diet and food consumption, it will be important to collect longitudinal data that detects these changes (Gonsalves and Hawk, 2014).

**Strengths and limitations**

The strength of this study is that we are working with a population that has been found to be representative for the Norwegian population, with a detailed registration of food intake, BMI, and sleep patterns, making it possible to compare the findings from this study with other studies. Food patterns and diet are influenced by culture, making the validity and reliability of the food intake questionnaires culturally conditioned. This may be a limitation when comparing our findings with other studies from non-western cultures. Another limitation is the descriptive design, as it does not allow for causal explanations of the associations between difficulties in falling asleep and unhealthy food patterns. Another important limitation to address is the sleep pattern questions that were developed especially for the Young-HUNT 3 study and are thus not validated. This must be taken into consideration when comparing the findings of this study with other studies.

**Conclusion**

This study found a statistically significant association between unhealthy food patterns and difficulties in falling asleep among Norwegian adolescents. The mechanisms explaining why this association is present needs further investigation. The importance of sleep in relation to obesity should be included in lifestyle recommendations for adolescents, as these conventionally have focused only on food consumption and exercise. Thus, the knowledge about associations between BMI, food patterns, and difficulties in falling asleep among Norwegian adolescents should be used in developing educational programs for both parents and adolescents to promote healthier sleeping and eating habits.
