S1 Synthesis of ZIF-8 and ZIF-67

For the synthesis of ZIF-8, two solutions were first prepared by dissolving 0.894 g of Zn(NO₃)₂·6H₂O in 30 mL of methanol and 0.984 g of 2-methylimidazole (2-MeIm) in 30 mL of methanol, respectively. Then, the solution of 2-MeIm was quickly poured into the solution of Zn(NO₃)₂·6H₂O, and the mixture solution was stirred for 24 h at room temperature. Lastly, the solution was centrifuged-washed five times with methanol and dried under vacuum at 60 °C for 12 h. ZIF-67 was synthesized with the same procedure of ZIF-8 except for the use of 0.873 g Co(NO₃)₂·6H₂O as metal precursor.

S2 Synthesis of ZIF-8@ZIF-67 and CZIFs Material

In a typical run, 100 mg of ZIF-8 polyhedrons as the seeds were dispersed in 30 mL of methanol. Then 10 mL, 32.8 mg·mL⁻¹ methanol solution and 150 mg of Co(NO₃)₂·6H₂O were added into the suspension of ZIF-8 polyhedrons under magnetic stirring with 300 rpm. After stirring for 24 h, the ZIF-8@ZIF-67 core-shell particle was centrifuged-washed five times at 8000 rpm with methanol and dried under vacuum at 60 °C for 12 h. The as-prepared ZIF-8@ZIF-67 particles were annealed at 800 °C for 5 h under an argon gas flow with a heating rate of 10 °C/min, and the yielding black powder was moved to a 50 mL centrifuge tube and then added 10 mL 0.5 M H₂SO₄ solution with a water bath at 80 °C for 12 h to remove the unstable metal species. The black powder was centrifuged with 8000 rpm and washed three times by ultrapure water and then dried under vacuum at 60 °C for 6 h.

S4 Optimization of Experimental Conditions

As illustrated in Figure S4a, with the increase of the concentration of CZIFs from 0.25 to 1.0 mg·mL⁻¹, the ΔI reached the maximum at 0.5 mg·mL⁻¹, indicating that 0.5 mg·mL⁻¹ of CZIFs was sufficient for the reaction. Therefore, 0.5 mg·mL⁻¹ was selected as the suitable concentration of CZIFs material. The different concentrations of aptamer was optimized and the ΔI got the maximum value at 0.5 μM (Figure S4b). Therefore, 5 μM was selected as the suitable aptamer concentration. As shown in Figure S4c, the pH of buffer solution was optimized. With the increased the concentration of pH, the ΔI reached the maximum at 5.5, indicating that pH 5.5 was the most suitable in the below experiments. As shown in Figure S4d, above 40 mins, the ΔI signal almost kept invariable, suggesting that 40 mins was suitable as the incubating time of aptasensor and Pb²⁺. Hence, the incubating 40 mins was adopted in the following work.

Figure S2. Optimization of the experimental parameters: (a) concentration of porous carbon, (b) concentration of aptamer, (c) pH of buffer solution, (d) different incubation time on aptasensor with Pb²⁺.
