Mussel *Mytilus galloprovincialis* is a marine aquaculture shellfish distributing widely along the coast in north China. In this work, we studied the differential metabolic responses induced by *Vibrio harveyi* in digestive gland and gill tissues from *M. galloprovincialis* using NMR-based metabolomics. The differential metabolic responses in the two tissue types were detected, except the similarly altered taurine and betaine. These metabolic responses suggested that *V. harveyi* mainly induced osmotic disruption and reduced energy demand via the metabolic pathways of glucose synthesis and ATP/AMP conversion in mussel digestive gland. In mussel gill tissues, *V. harveyi* basically caused osmotic stress and possible reduced energy demand as shown by the elevated phosphocholine that is involved in one of the metabolic pathways of ATP synthesis from ADP and phosphocholine. The altered mRNA expression levels of both lysozyme and defensin in digestive gland were more significantly up-regulated than those in gill from *V. harveyi*-challenged mussel *M. galloprovincialis*, meaning that the immune organ, digestive gland, was more sensitive than gill. Overall, our results indicated that *V. harveyi* could induce tissue-specific metabolic responses in mussel *M. galloprovincialis*.

1. Introduction

Vibrios, such as *Vibrio anguillarum*, *Vibrio alginolyticus*, *Vibrio splendidus*, *Vibrio furnissii*, *Vibrio paraahemolyticus*, *Vibrio tapetis* and *Vibrio harveyi*, are widely distributed in marine environments and main causative pathogens of vibriosis in both fish and shellfish [1,2]. As a type of vibrios, *V. harveyi* is a gram-negative bacterium and its outbreak is a causative agent for the massive mortality of marine aquaculture animals including fish, crustacean and mollusk in warm seas [3,4]. Marine bivalves such as scallop *Chlamys farreri*, oyster *Crassostrea gigas*, clam *Ruditapes philippinarum* and mussel *Mytilus galloprovincialis* are of substantial economic values and therefore widely cultured in China. The blue mussel *M. galloprovincialis* has a wide geographic distribution and can be consumed as delicious seafood by the residents along the coast in north China. As a filter-feeder, *M. galloprovincialis* is not only a good bioindicator in marine ecotoxicology [5,6], but also used in immunity studies of marine aquaculture animals due to its high accumulation and susceptibility to pathogens [7–9]. For example, Canesi et al. found that infections of vibrios (*V. splendidus* and *V. anguillarum*) induced oxidative and immune stresses in *M. galloprovincialis*, indicated by significant up-regulations of gene expression levels of immune stress-responsive molecules, including anti-oxidant enzymes (catalese and glutathione transferase), lysozymes and metallothioneins [8].

In many previous immunity studies, researchers focused on the special immune-related molecules and their functions involved in immune network in *M. galloprovincialis* [7–10]. With the development of system biology techniques (genomics, transcriptomics, proteomics and metabolomics), researchers have applied these -omic approaches to fish and shellfish immunology, which can provide a comprehensive understanding of immune responses of marine aquaculture animals to pathogen challenges [11,12]. Recently, Ji et al. reported the proteomic responses in *M. galloprovincialis* challenged by another vibrio, *V. anguillarum* [12]. They found that the infection of *V. anguillarum* caused disruption in energy metabolism and oxidative stress in *M. galloprovincialis*, indicated by the proteomic biomarkers, including procollagen-proline dioxygenase, protein disulfide...
Mussels were kept at 25 °C, seawater was renewed daily. During the acclimation period, animals containing 15 individuals in 30 L tanks were acclimated for 10 days. After acclimatization, the animals were randomly divided into three groups (blank, PBS control and V. harveyi challenge) each containing 15 individuals in 30 L filtered seawater. The culture seawater was renewed daily. During the acclimation period, animals were kept at 25 °C under a photoperiod of 12 h light and 12 h dark, and fed with the Chlorella vulgaris at a ration of 2% tissue dry weight daily.

2.2. Challenge experiment

The bacterium, V. harveyi, was kindly provided by Prof. Baozhong Liu (Institute of Oceanology, CAS). The bacteria were cultured in liquid 2216E broth (Tryptone 5 g L⁻¹, yeast extract 1 g L⁻¹, CaH₂Fe₅H₂O 0.1 g L⁻¹, pH 7.6) at 29 °C and centrifuged at 3000 g for 5 min to harvest the bacteria. For challenge experiment, live bacteria of V. harveyi were re-suspended in PBS. Each challenged mussel was injected with V. harveyi (10⁵ CFU/mL) in 50 μL of PBS (137 mM NaCl, 2.7 mM KCl, 10 mM Na₂HPO₄, 2 mM KH₂PO₄, pH 7.4) in the adductor muscle. It should be noted that this concentration of bacteria was used to study the differential metabolic effects and mechanisms induced by V. harveyi in digestive gland and gill tissues of M. galloprovincialis using NMR-based metabolomics.

2.3. Metabolite extraction

Polar metabolites in mussel digestive gland and gill tissues (n = 15 for each treatment) were extracted by the modified extraction protocol as described previously [17,18]. Briefly, the tissue (100 mg) was homogenized in 400 μL of methanol and 85 μL of water. Then the mixture was shaken and centrifuged (5 min, 3000 g, at 4 °C), and the supernatant substance was transferred into a glass vial. A total of 200 μL of chloroform and 440 μL of water were added to the supernatant, and the mixture was vortexed and centrifuged again (10 min, 3000 g, 4 °C). The methanol/water layer with polar metabolites was transferred to a glass vial and dried in a centrifugal concentrator. The extracts of tissues were then re-suspended in 600 μL of phosphate buffer (100 mM Na₂HPO₄ and NaH₂PO₄, including 0.5 mM 2,2,3,3-d(4)-3-(trimethylsilyl)propionic acid sodium salt (TSP) as the internal standard, pH 7.0) in D₂O. The mixture was vortexed and centrifuged at 3000 g for 5 min at 4 °C. The supernatant substance (550 μL) was then pipetted into a 5 mm NMR tube prior to NMR analysis.

2.4. RNA extraction and quantitation of gene expressions

Total RNA from mussel digestive gland and gill tissues was extracted following the manufacturer’s directions (Invitrogen, LifeTechnologies, Carlsbad, CA, USA), and the first-strand cdDNA was synthesized according to M-MLV RT Usage information (Promega, Madison, WI, USA). The expressions of the housekeeping genes in M. galloprovincialis were determined by real-time quantitative PCR (qRT-PCR), the data were analyzed with geNorm to calculate the expression stability of the genes (M values) and the optimal number of reference genes required for accurate normalization (V values) [19]. GeNorm identified β-actin as the most stable gene which was then used as the internal control for gene expression normalization (data not shown).

Gene-specific primers (Table 1) for selected genes were used to amplify amplicons specific for M. galloprovincialis. The fluorescent qRT-PCR amplifications were carried out in triplicate in a total volume of 20 μL containing 10 μL of 2 × SYBR Premix Ex Taq™ (TaKaRa), 0.4 μL of 50 × ROX Reference DYE II, 4.8 μL DEPC-treated H₂O, 0.4 μL of each primer, 4.0 μL of 1:20 diluted cdDNA. The qRT-PCR program was as follows: 50 °C for 2 min and 95 °C for 10 min, followed by 40 cycles of 94 °C for 15 s, 58 °C for 45 s, 72 °C for 30 s. Dissociation curve analysis of amplification products was performed at the end of each PCR to confirm that only one PCR product was amplified and detected. After the PCR program, data were analyzed with the ABI 7500 SDS software (Applied Biosystems). To maintain consistency, the baseline was set automatically by the software. The comparative CT method (2⁻ΔΔCT method) was used to analyze the expression level of the genes [20]. One-way ANOVA combined with Tukey’s test was performed on mRNA expression levels between PBS control and V. harveyi-challenged groups, respectively. A P value less than 0.05 was considered statistically significant. The Minitab software (Version 15, Minitab Inc., USA) was used for the statistical analysis.

2.5. ¹H NMR spectroscopy

Metabolite extracts of tissues from mussels were analyzed on a Bruker AV 500 NMR spectrometer performed at 500.18 MHz (at

and PBS groups was found (data not shown), which suggested that no significant separation between blank and PBS control groups. However, no significant separation between blank and PBS control groups was found (data not shown), which suggested that the distributions of adenosine and AMP were significantly different between these two tissues. Clearly, the corresponding loading plot (Fig. 2B) displayed the higher levels of most amino acids (threonine, alanine, glutamate, glutamine, etc.) and glucose, as well as the higher levels of taurine and homarine and lower levels of aspartate and betaine in digestive glands than those in gills. These biological (metabolic) differences between digestive gland and gill tissues suggested the potential differential metabolic responses in these two organs towards *V. harveyi* challenge.

3.2. Differential metabolic responses in digestive gland and gill tissues from *M. galloprovincialis* challenged by *V. harveyi*

O-PLS-DA was conducted on the $^1$H NMR spectral data to characterize the metabolic responses in digestive gland and gill tissue samples from PBS control group, respectively (Fig. 3). Fig. 3A and C indicated that O-PLS-DA resulted in clear classifications between PBS control and *V. harveyi*-challenged mussel groups, respectively, with reliable $Q^2$ values (>0.7). From the loading plot (Fig. 3B), the concentrations of adenosine and AMP were significantly ($P < 0.05$) increased in *V. harveyi*-challenged mussel digestive gland. The

**3. Results and discussion**

### 3.1. Metabolic differences in digestive gland and gill tissues from *M. galloprovincialis* from PBS control group

As a system biology technique, metabolomics has been widely employed in multiple areas, including toxicology and immunology [11,13,25–30]. Fig. 1 indicates the $^1$H NMR spectra of tissue extracts of digestive gland (Fig. 1A) and gill (Fig. 1B) samples from PBS control mussel group. The identified metabolites, including amino acids (branched chain amino acids: valine, leucine and isoleucine, aspartate, glutamate, glutamine, tyrosine phenylalanine, etc.), energy storage compounds (ATP, glucose and glycogen), an intermediate in Krebs cycle (succinate), osomyostes (betaine, taurine, glycine and homarine) and a phosphagen (phosphocholine), were labeled in Fig. 1. As shown in Fig. 1, both $^1$H NMR spectra are dominated by the organic osmyostes, betaine (3.27 and 3.90 ppm), which is synthesized from a two-step reaction of choline: choline $\rightarrow$ betaine aldehyde $\rightarrow$ NAD $^+$ $\rightarrow$ betaine $\rightarrow$ NADH [31]. Since digestive gland is the main organ of glucose and protein metabolisms, the $^1$H NMR spectrum from the digestive gland sample should present the higher levels of most amino acids and glucose than those in the $^1$H NMR spectrum from the gill sample. Initially, O-PLS-DA was performed on the NMR spectral datasets from the blank and PBS control groups. However, no significant separation between blank and PBS groups was found (data not shown), which suggested that the single injection of PBS in the adductor muscle did not obviously affect the metabolic profiles in both digestive gland and gill tissues. Therefore, only PBS control was used in further data analysis. O-PLS-DA analysis resulted in a clear separation between the digestive gland and gill samples from PBS control group (Fig. 2A), with a $Q^2$ value greater than 0.9 showing the robustness of the constructed model, which confirmed the significant metabolic differences between these two tissues. Clearly, the corresponding loading plot (Fig. 2B) displayed the higher levels of most amino acids (threonine, alanine, glutamate, glutamine, etc.) and glucose, as well as the higher levels of taurine and homarine and lower levels of aspartate and betaine in digestive glands than those in gills. These biological (metabolic) differences between digestive gland and gill tissues suggested the potential differential metabolic responses in these two organs towards *V. harveyi* challenge.
levels of aspartate, dimethylglycine, glucose, ATP, taurine and betaine were significantly ($P < 0.05$) decreased. Adenosine plays important roles in both energy transfer as adenosine triphosphate (ATP) and adenosine diphosphate (ADP), as well as in signal transduction as cyclic adenosine monophosphate [32]. In the digestive gland from *V. harveyi*-challenged mussels, the depleted ATP meant a reduced energy demand resulting in the elevated AMP meant a reduced energy demand resulting in the elevated adenine and depleted glucose. Apparently, the increased AMP was resulted in the enhanced hydrolysis of ATP, which was also observed in *V. splendidus*-challenged sea cucumber *Apostichopus japonicas* [33]. Dimethylglycine, taurine and betaine are osmolytes in animals. The decreased dimethylglycine, taurine and betaine probably indicated the osmotic stress induced by *V. harveyi* challenge in mussel digestive gland. The level of aspartate was significantly decreased in *V. harveyi*-challenged mussel digestive gland tissues. In marine mollusks, amino acids can be used to regulate animals’ intracellular osmolarity with the environment and also can be oxidized to generate energy [34]. In the energy metabolic pathway, there is substantial conversion of aspartate to succinate with no detectable enrichment of other metabolites under anoxic conditions in mullusk [35]. However, both ATP and glucose were decreased and succinate was not altered in *V. harveyi*-challenged mussel digestive gland. Therefore, the decrease of aspartate could be related to the disruption in osmotic regulation but in energy metabolisms in *V. harveyi*-challenged mussel digestive gland. In a previous study on the effects of *V. harveyi* challenge towards clam *Ruditapes philippinarum*, the elevation of branched chain amino acids (BCAA) was observed in digestive gland of *R. philippinarum* [36]. In the metabolic pathways of innate immunity, BCAAs have an availability on the immune system to function by incorporating BCAAs into proteins, resulting in a remarkable increase in demand for BCAAs for substrates by the immune system [37]. In this work, however, BCAAs were not altered in *V. harveyi*-challenged mussel digestive gland, which suggested the differential responsive mechanisms between mussel *M. galloprovincialis* and *R. philippinarum* to *V. harveyi* challenge.

The metabolic responses in the gill tissues of *V. harveyi*-challenged mussels were different from those in the digestive gland samples. As shown in the corresponding loading plot of O-PLS-DA (Fig. 3D), phosphocholine, hypotaurine, glycine, homarine and an unknown metabolite (1.10 ppm) were increased in *V. harveyi*-challenged mussel gill samples (Fig. 3D). Two organic osmolytes, taurine and betaine were significantly ($P < 0.05$) decreased, which was similar to their alteration in digestive gland of *V. harveyi*-challenged mussels (Fig. 3B). The elevated organic osmolytes, including hypotaurine, homarine and glycine, clearly indicated the osmotic stress caused by *V. harveyi* challenge in the gill of mussel *M. galloprovincialis*. However, other two osmolytes, taurine and betaine were depleted. Since taurine can be synthesized into hypotaurine, the decrease of taurine meant the enhanced synthesis of hypotaurine from taurine, resulting in an increase of hypotaurine in *V. harveyi*-challenged mussel gill samples. Similarly, betaine is synthesized from glycine. Therefore, the depletion of betaine combined with the elevation of glycine indicated the reduced synthesis of betaine *V. harveyi*-challenged mussel gill samples. Ji et al. reported the similar metabolic responses including depleted taurine and betaine and elevated homarine in gill tissues from mussel *M. galloprovincialis* challenged by *V. anguillarum*, which implied the similar disturbance in osmotic regulation induced by both *V. anguillarum* and *V. harveyi* in mussel gills [12]. As a phosphagen, phosphocholine is involved in the conversion of ATP and choline into phosphocholine and ADP, which is catalyzed by choline kinase. Therefore, the elevated phosphocholine probably meant a reduced energy demand in *V. harveyi*-challenged mussel gills via a different metabolic pathway compared with that in digestive gland, as mentioned above.

### 3.3. Stress-responsive gene expressions in digestive gland and gills from *M. galloprovincialis* challenged by *V. harveyi*

In this study, four stress-responsive genes including heat shock protein 90 (HSP90), superoxide dismutase with copper and zinc (Cu/Zn-SOD), defensin and goose-type lysozyme related to diverse functions were used for the quantification of mRNA expressions. HSP90, Cu/Zn-SOD, defensin and lysozyme play important roles in anti-oxidative stress and immune defense. After *V. harveyi* injection, the mRNA expression levels of HSP90, Cu/Zn-SOD, defensin and lysozyme mRNA in both digestive gland and gill tissues were quantified using qRT-PCR technique with $\beta$-actin as internal control (Fig. 4). All the mRNA expression levels of these four selected stress-responsive genes were significantly ($P < 0.05$) up-regulated in *V. harveyi*-challenged mussel digestive gland and gill tissues (Fig. 4). Cu/Zn-SOD is a known anti-oxidant enzyme involved in scavenging reactive oxygen species and HSP90 belongs to a large family of molecular chaperones playing vital roles in preventing irreversible protein denaturation, aggregation and misfolding [38,39]. They can be induced by oxidative stress and pathogen infection [38]. Both
defensin and lysozyme are antibacterial components that have been characterized in marine mollusks [40,41]. In this work, the significant up-regulation of mRNA expression levels of Cu/Zn-SOD, HSP90, defensin and lysozyme indicated the oxidative and immune stresses induced by *V. harveyi* in both digestive gland and gill samples from *V. harveyi*-challenged mussels. Consequently, metabolites that are more abundant in the control group are presented as peaks in the negative direction. *Keys:* (1) aspartate, (2) dimethylglycine, (3) taurine, (4) betaine, (5) adenosine, (6) β-glucose, (7) α-glucose, (8) AMP, (9) ATP, (10) unknown 1 (1.10 ppm), (11) phosphocholine, (12) hypotaurine, (13) glycine and (14) homarine.

In summary, the differential metabolic responses induced by *V. harveyi* in digestive gland and gill tissues from *M. galloprovincialis*

![Fig. 3. O-PLS-DA scores plots derived from 1H NMR spectra of tissue extracts from PBS control (a) and *V. harveyi*-challenged (■) groups, (A) digestive gland and (C) gill and corresponding coefficient plots (B) and (D). The color map shows the significance of metabolite variations between the two classes (control and *V. harveyi* challenge). Peaks in the positive direction indicate metabolites that are more abundant in the *V. harveyi*-challenged groups. Consequently, metabolites that are more abundant in the control group are presented as peaks in the negative direction. *Keys:* (1) aspartate, (2) dimethylglycine, (3) taurine, (4) betaine, (5) adenosine, (6) β-glucose, (7) α-glucose, (8) AMP, (9) ATP, (10) unknown 1 (1.10 ppm), (11) phosphocholine, (12) hypotaurine, (13) glycine and (14) homarine.](image)

Statistical significances (*P* < 0.05, *) between control and *V. harveyi*-challenged *M. galloprovincialis* samples were determined by one-way ANOVA. *Abbreviations:* Cu/Zn-SOD, superoxide dismutase with copper and zinc and HSP90, heat shock protein 90.](image)
were investigated using NMR-based metabolomics. Overall, V. harveyi induced osmotic disruption and reduced energy demand via the metabolic pathways of glucose synthesis and ATP/AMP conversion in mussel digestive gland. In mussel gill tissues, V. harveyi basically caused osmotic stress and possible reduced energy demand through the metabolic pathway of conversion of phosphocholine and ADP to choline and ATP. The altered mRNA expression levels of related genes (Cu/Zn-SOD, HSP90, defensin and lysozyme) suggested that V. harveyi induced clear oxidative and immune stresses in both digestive gland and gill tissues. However, the mRNA expression levels of both lysozyme and defensin in digestive gland were more significantly up-regulated than those in gill from V. harveyi-challenged mussel M. galloprovincialis. This work demonstrated that V. harveyi could induce tissue-specific metabolic responses in the digestive gland and gill tissues from mussel M. galloprovincialis using NMR-based metabolomics.
