Abstract

The nucleon resonances are investigated within a dynamical coupled-channels model of $\pi N$ and $\gamma N$ reactions up to the invariant mass $W = 2$ GeV. The meson-baryon ($MB$) channels included in the calculations are $MB = \pi N$, $\eta N$, $K \Lambda$, $K \Sigma$, and $\pi \pi N$ that has $\pi \Delta$, $\rho N$, and $\sigma N$ resonant components. The meson-baryon amplitudes $T_{M'B',MB}(W)$ are calculated from solving a set of coupled-channels integral equations defined by an interaction Hamiltonian consisting of (a) meson-exchange interactions $v_{MB,M'B'}$ derived from phenomenological Lagrangian, and (b) vertex interactions $N^* \rightarrow MB$ for describing the transition of a baryon $B$ to a bare excited nucleon state $N^*$. The parameters of $v_{MB,M'B'}$ are mainly constrained by the fit to the data of $\pi N \rightarrow \pi N$ in the low energy region up to $W = 1.4$ GeV. The bare masses of $N^*$ and the $N^* \rightarrow MB$ parameters are then determined in simultaneous fits to the data of $\pi N \rightarrow \pi N$ up to $W = 2.3$ GeV and those of $\pi N \rightarrow \eta N, K \Lambda, K \Sigma$ and $\gamma N \rightarrow \pi N, \eta N, K \Lambda, K \Sigma$ up to $W = 2.1$ GeV. The pole positions and residues of nucleon resonances are extracted by analytically continuing the meson-baryon amplitudes $T_{M'B',MB}(W)$ to the complex Riemann energy surface. From the extracted residues, we have determined the $N^* \rightarrow \pi N, \gamma N, \eta N, K \Lambda, K \Sigma$ transition amplitudes at resonance poles. We compare the resonance pole positions from our analysis with those given by Particle Data Group and the recent coupled-channels analyses by the Jülich and Bonn-Gatchina groups. Four results agree well only for the first $N^*$ in each spin-parity-isospin $(J^P,I)$ channel. For higher mass states, the number of states and their resonance positions from four results do not agree well. We discuss the possible sources of the discrepancies and the need of additional data from new hadron facilities such as J-PARC.

I. INTRODUCTION

One of the important problems in hadron physics is to understand the structure of the nucleon within Quantum Chromodynamics (QCD). Since the nucleon is a composite particle, its properties are closely related to the spectrum and the structure of its excited states. From the available data, we know that all of the excited nucleon states (denoted collectively as $N^*$) are unstable and couple strongly with the meson-baryon continuum states to form resonances in $\pi N$ and $\gamma N$ reactions. Therefore, the study of the $N^*$ resonances in $\pi N$ and $\gamma N$ reactions has been a well-recognized important task in advancing our understanding of the structure of baryons. It can also provide important information for understanding how the confinement and chiral symmetry breaking emerge from QCD.

In this work, we report on the results from an investigation of $N^*$ resonances with an extension of the dynamical coupled-channels (DCC) model developed in Ref. [1]. Schematically, the following coupled-channels integral equations in each partial wave are solved within the DCC model of Ref. [1],

$$T_{\beta,\alpha}(p_\beta, p_\alpha; W) = V_{\beta,\alpha}(p_\beta, p_\alpha; W) + \sum_\gamma \int p^2 dp V_{\beta,\gamma}(p_\beta, p; W) G_\gamma(p; W) T_{\gamma,\alpha}(p, p_\alpha; W), \quad (1)$$

with

$$V_{\beta,\alpha}(p_\beta, p_\alpha; W) = v_{\beta,\alpha}(p_\beta, p_\alpha) + \sum_{N^*} \frac{\Gamma_{N^*,\beta}^\dagger(p_\beta) \Gamma_{N^*,\alpha}(p_\alpha)}{W - M_{N^*}^0}, \quad (2)$$

where $\alpha, \beta, \delta = \gamma N, \pi N, \eta N$, and $\pi \pi N$ that has the unstable $\pi \Delta, \rho N$, and $\sigma N$ components, $G_\delta(p; W)$ is the Green function of the channel $\delta$, $M_{N^*}^0$ is the mass of a bare excited nucleon state $N^*$, $v_{\beta,\alpha}$ is defined by the meson-exchange mechanisms, and the vertex interaction $\Gamma_{N^*,\alpha}$ defines the $\alpha \to N^*$ transition. We will describe in Sec. II how Eqs. (1) and (2) can be cast into a form which is most convenient for extracting the nucleon resonances from the amplitude $T_{\beta,\alpha}(p_\beta, p_\alpha; W)$. In the past few years, we have applied this DCC model to analyze $\pi N$ and $\gamma N$ reactions with $\pi N$ [2–4], $\eta N$ [5], and $\pi \pi N$ [6, 7] final states. The method for extracting the nucleon resonances within the considered DCC model was developed in Refs. [8, 9] with the results presented in Refs. [9–11]. During this developing stage, the DCC model parameters were not determined by simultaneous fits to all of considered data. In addition, the very extensive data of $K \Lambda$ and $K \Sigma$ photoproduction reactions were not included in the analysis. As a step in improving our analysis, we have extended these earlier efforts to perform a combined analysis of the available data for $\pi N, \gamma N \to \pi N, \eta N, K \Lambda, K \Sigma$. The purpose of this paper is to report on the results from this effort.

The starting point of our analysis is to extend the model, defined by Eqs. (1) and (2), to include the $K \Lambda$ and $K \Sigma$ channels. We then apply the same numerical procedures detailed in our previous publications [1, 2, 8] to perform the calculations. Our main effort is to determine the parameters of the interactions $V_{\beta,\alpha}$ of Eq. (2) by fitting simultaneously all of the rather extensive data, as will be explained later. The nucleon resonances are then extracted from the resulting model by using the analytic continuation method developed in Refs. [8, 9].

The extraction of nucleon resonances has a long history and several different approaches have been developed. To see the main features of our approach, as well as the other dynamical models [12–20], we briefly discuss how the nucleon resonances are extracted by the other
analysis groups. It is common to parameterize the partial-wave amplitudes in terms of polynomial functions, the Breit-Wigner forms, the tree-diagrams of phenomenological Lagrangian, or various combinations of them. The K-matrix method is used in these analyses to unitarize the constructed amplitudes. In most cases, the resulting forms of partial-wave amplitudes depend algebraically on the energy variable \( W \) and hence it is rather efficient numerically to fit the data and extract the resonances. The analyses based on the unitary Carnegie-Mellon-Berkeley model also only involve solving algebraic equations in extracting the resonances from the partial-wave amplitudes. In a approach based on a DCC model, such as the one defined by Eqs. (1) and (2), the partial-wave amplitudes are calculated by solving a set of coupled-channels integral equations. Thus the computation effort needed in fitting the meson production data is considerably more complex than that of the K-matrix analyses. Furthermore, the resulting partial-wave amplitudes, defined by the coupled-channels integral equations such as Eqs. (1) and (2) used in our analysis, have complicated analytic structure and must be analyzed carefully to develop a correct procedure for extracting the nucleon resonances.

Compared with the models with polynomial parameterizations of the partial-wave amplitudes, our approach as well as all dynamical models have an important constraint in fitting the data. In the polynomial fits, the parameters in each partial-wave of each channel are adjusted independently. On the other hand, the dynamical models have much less freedom in adjusting the parameters to fit the data since the partial-wave amplitudes in all partial waves and in all reaction channels are related to the same parameters of the meson-exchange mechanisms.

Obviously, a DCC approach is much more complex and difficult than the other approaches. This however is needed to investigate the dynamical origin and the internal structure of the nucleon resonances. As can be seen from the ingredients of the interaction \( V_{\beta,\alpha}(p_\beta,p_\alpha;W) \) in Eq. (2), the dynamical model considered in our approach is aimed at exploring a question whether a nucleon resonance can be interpreted as a system of a core state surrounded by a meson cloud, a molecule-like meson-baryon state, or a mixture of them. Such an interpretation has been obtained for the \( \Delta \) (1232) resonance in various meson-exchange models of \( \pi N \) and \( \gamma N \) reactions up to \( W = 1.3 \) GeV. An example can be found in Ref. [15], where \( \Delta(1232) \) was interpreted as a baryon made of a core state and a pion cloud. The resulting core state can be identified, qualitatively, with the \( \Delta \) of a hadron structure model with only constituent-quark degrees of freedom. Our earlier DCC analysis [10, 11] has also provided useful information on the dynamical origin of the Roper resonance, and has provided an interpretation of the mass of the first excited nucleon state with isospin-spin-parity \( I(J^P) = 1/2(1/2^+) \) predicted by most of the hadron structure models such as the model based on the Dyson-Schwinger equation of QCD [33]. The DCC analysis performed in this work is a necessary step toward improving our understanding of the dynamical origins and the structure of all nucleon resonances with mass below 2 GeV.

In Sec. [II] we briefly describe the formulation of the DCC model used in our analysis. The formula for extracting nucleon resonances developed in Refs. [8, 9] are reviewed in Sec. [III]. The procedures for determining the model parameters are explained in Sec. [IV]. The fits to the data are presented and discussed in Sec. [V]. The extracted nucleon resonances are given in Sec. [VI]. In Sec. [VII] we discuss the possible future developments. For completeness, we also explain the essential details of our calculations in Appendices [A-D]. The determined model parameters are given in Appendix [E].
II. DYNAMICAL COUPLED-CHANNELS MODEL

Since the formulation of the DCC model employed in this work has been given in detail in Refs. [1–4, 6, 7], here we only briefly describe the relevant equations that are needed to define the notations for presenting our results. We will also indicate several improvements we have made for performing the combined analysis of pion- and photon-induced $\pi N, \eta N, K\Lambda$, and $K\Sigma$ production reactions.

A. Hadronic amplitudes

Within the formulation of Ref. [1], we apply the projection operator method [34] to cast the partial-wave components of the $T$ matrix elements of the meson-baryon reactions, $M(\vec{k}) + B(-\vec{k}) \rightarrow M'(\vec{k}') + B'(-\vec{k}')$, into the following form

$$T_{M'B'MB}(k', k; W) = t_{M'B'MB}(k', k; W) + t_{R_{M'B'MB}}(k', k; W),$$

where $W$ is the total energy, $k$ and $k'$ are the meson-baryon relative momenta in the center of mass frame, and $MB, M'B' = \pi N, \eta N, \pi \Delta, \rho N, \sigma N, K\Lambda, K\Sigma$ are the reaction channels included in this analysis. [The label “$MB$” shall also specify quantum numbers (spin, parity, isospin etc) associated with the channel $MB$.]

The “non-resonant” amplitude $t_{M'B'MB}(k', k; W)$ in Eq. (3) is defined by a set of coupled-channels integral equations

$$t_{M'B'MB}(k', k; W) = V_{M'B'MB}(k', k; W) + \sum_{M''B''} \int_{C_{M'B'}} k''^2 dk'' V_{M'B'M''B''}(k', k''; W)$$

$$\times G_{M''B''}(k''; W) t_{M''B''M'B}(k'', k; W).$$

Here $C_{M'B'}$ is the integration path, which is taken from 0 to $\infty$ for the physical $W$; the summation $\sum_{MB}$ runs over the orbital angular momentum and total spin indices for all $MB$ channels allowed in a given partial wave; $G_{M''B''}(k; W)$ are the meson-baryon Green functions. Defining $E_\alpha(k) = [m_\alpha^2 + k^2]^{1/2}$ with $m_\alpha$ being the mass of a particle $\alpha$, the meson-baryon Green functions in the above equations are:

$$G_{MB}(k; W) = \frac{1}{W - E_M(k) - E_B(k) + i\epsilon},$$

for the stable $\pi N, \eta N, K\Lambda$, and $K\Sigma$ channels, and

$$G_{MB}(k; W) = \frac{1}{W - E_M(k) - E_B(k) - \Sigma_{MB}(k; W)},$$

for the unstable $\pi \Delta, \rho N$, and $\sigma N$ channels. The details of the self energy $\Sigma_{MB}(k; W)$ in Eq. (6) are given in Appendix A. The branch points of the meson-baryon Green functions $G_{MB}(k; W)$, as defined by zeros of the denominator of Eqs. (5) and (6), are related closely

---

1 Because of perturbative nature of the electromagnetic interactions, it is only necessary to solve the coupled-channels equations in the channel space excluding the $\gamma N$ channel. The $\gamma N \rightarrow \pi N$ amplitude up to the order of $\epsilon = \sqrt{4\pi/137}$ can then be calculated perturbatively, as can be seen in Sec. II B.
TABLE I. Branch points of the meson-baryon Green functions $G_{MB}(k; W)$ for unstable-channels $MB = \pi \Delta, \sigma N, \rho N$. For the calculation of the Green functions, we take $m_N = 938.5 \text{ MeV}$ and $m_\pi = 138.5 \text{ MeV}$.

| Branch point (MeV) | Branch point (MeV) |
|-------------------|-------------------|
| $\pi \Delta$     | $(1211.5 - i55.0) + m_\pi$ |
| $\sigma N$       | $(483.7 - i185.8) + m_N$ |
| $\rho N$         | $(1032.3 - i247.7) + m_N$ |

![FIG. 1. Meson-exchange mechanisms.](image)

The driving terms of Eq. (4) are

$$V_{M'B',MB}(k', k; W) = v_{M'B',MB}(k', k) + Z_{M'B',MB}^{(E)}(k', k; W).$$

Here the potentials $v_{M'B',MB}(k', k)$ are meson-exchange interactions derived from the tree-diagrams, as illustrated in Fig. 1 of phenomenological Lagrangian. Within the unitary transformation method \[15, 35–37\] used in the derivation, those potentials are energy independent and free of singularities. In Appendix B we list the Lagrangian used in our derivations. The resulting forms of $v_{M'B',MB}(k', k)$ and their partial-wave expansions are given in Appendix C.

The energy-dependent $Z_{M'B',MB}^{(E)}(k', k; W)$ terms in Eq. (7), as illustrated in Fig. 2, contain the moving singularities due to the three-body $\pi \pi N$ cut. These $Z$-diagram terms were neglected in the fit of Ref. [2], and are now included in this combined analysis. With this inclusion of the $Z$-diagram terms, we have confirmed that our model satisfies the three-body $\pi \pi N$ unitarity perfectly within the numerical accuracy. The procedures for evaluating the partial-wave matrix elements of $Z_{M'B',MB}^{(E)}(k', k; W)$ are explained in detail in Appendix E of Ref. [1].

The second term in the right-hand-side of Eq. (3) is the $N^*$-excitation term defined by

$$t_{M'B',MB}^{R}(k', k; W) = \sum_{N^*_n,N^*_m} \bar{\Gamma}_{M'B',N^*_n}(k'; W)[D(W)]_{n,m} \bar{\Gamma}_{N^*_m,MB}(k; W).$$

Here the dressed $N^* \to MB$ and $MB \to N^*$ vertices are, respectively, defined by

$$\bar{\Gamma}_{MB,N^*}(k; W) = \Gamma_{MB,N^*}(k) + \sum_{M'^*} \int q^2 dq t_{MB,M'^*}(k, q; W) G_{M'^*}(q; W) \Gamma_{M'^*,N^*}(q).$$
\[
\Gamma_{N^*,MB}(k; W) = \Gamma_{N^*,MB}(k) + \sum_{M'B'} \int q^2 dq \Gamma_{N^*,M'B'}(q) G_{M'B',MB}(q,k;W),
\]
with \(\Gamma_{MB,N^*}(k)\) being the bare \(N^* \rightarrow MB\) decay vertex [note that \(\Gamma_{N^*,MB}(k) = \Gamma_{MB,N^*}^\dagger(k)\)]; the inverse of the dressed \(N^*\) propagator is defined by
\[
[D^{-1}(W)]_{n,m} = (W - M^0_{N^*}) \delta_{n,m} - [\Sigma_{N^*}(W)]_{n,m},
\]
where \(M^0_{N^*}\) is the mass of the bare \(N^*\) state and the \(N^*\) self-energies \(\Sigma_{N^*}(W)\) are given by
\[
[\Sigma_{N^*}(W)]_{n,m} = \sum_{MB} \int_{CMB} k^2 dk \Gamma_{N^*,MB}(k) G_{MB}(k;W) \bar{\Gamma}_{MB,N^*_m}(k;W).
\]
We emphasize here that the \(N^*\) propagator \(D(W)\) can have off-diagonal terms due to the meson-baryon interactions.

Equations (3)-(12) define the DCC model used in our analysis. In the absence of theoretical input, the DCC model, as well as all hadron reaction models, has parameters that can only be determined phenomenologically from fitting the data. The meson-exchange interactions \(v_{M'B',MB}\) depend on the coupling constants and the cutoffs of form factors that regularize their matrix elements. While the values of some of the coupling constants can be estimated from the flavor SU(3) relations, we allow most of them to vary in the fits. The s-channel and u-channel mechanisms of \(v_{M'B',MB}\) (\(v^s\) and \(v^u\) in Fig. 2) include at each meson-baryon-baryon vertex a form factor of the following form
\[
F(\tilde{k},\Lambda) = \left(\frac{\Lambda^2}{\tilde{k}^2 + \Lambda^2}\right)^2,
\]
with \(\tilde{k}\) being the meson momentum. For the meson-meson-meson vertex of t-channel mechanism (\(v^t\)), the form Eq. (13) is also used with \(\tilde{k}\) being the momentum of the exchanged meson. For the contact term (\(v^c\)) we regularize it by \(F(\tilde{k}',\Lambda') F(\tilde{k},\Lambda)\). The bare vertex functions in Eqs. (9) and (10) are parameterized as
\[
\Gamma_{MB(LS),N^*}(k) = \frac{1}{(2\pi)^{3/2}} \frac{1}{\sqrt{m_N}} C_{MB(LS),N^*} \left(\frac{\Lambda_{N^*}^2}{\Lambda_{N^*}^2 + k^2}\right)^{(2+L/2)} \left(\frac{k}{m_\pi}\right)^L,
\]
where \(L\) and \(S\) denote the orbital angular momentum and spin of the \(MB\) state, respectively. All of the possible \((L, S)\) states in each partial wave included in our coupled-channels calculations are listed in Table. II. The vertex function (14) behaves as \(k^L\) at \(k \sim 0\) and \(k^{-4}\) for \(k \rightarrow \infty\). The coupling constant \(C_{MB(LS),N^*}\) and the cutoff \(\Lambda_{N^*}\) are adjusted along with the bare masses \(M_{N^*}^0\) in the fits. It is noted that in our early analysis [2], the different cutoffs were introduced for each \(MB(LS)\) state of a given bare \(N^*\), and those were allowed to vary independently in the fit. In this analysis, however, we use a single cutoff \(\Lambda_{N^*}\) for all \(MB(LS)\) states. This drastically reduces the number of parameters associated with the hadronic interaction of the bare \(N^*\) states.

FIG. 2. Z-diagram mechanisms.
TABLE II. The orbital angular momentum \((L)\) and total spin \((S)\) of each \(MB\) channel allowed in a given partial wave. In the first column, partial waves are denoted with the conventional notation \(l_{IJ}\) as well as \((I,J^P)\).

B. Electromagnetic amplitudes

With the hadronic amplitudes \(t_{M'B',MB}(k',k;W)\) defined in Eq. [4], the partial wave amplitudes for the \(\gamma(q) + N(-q) \rightarrow M'(k') + B'(-k')\) reactions are expressed as [1],

\[
T_{M'B',\gamma N}(k',q;W) = t_{M'B',\gamma N}(k',q;W) + t_{M'B',\gamma N}^R(k',q;W),
\]  

(15)
with

\[
t_{M'B',\gamma N}(k',q;W) = v_{M'B',\gamma N}(k',q) \\
+ \sum_{M''B''} \int p^2 dp t_{M'B',M''B''}(k',p;W)G_{M''B''}(p;W)v_{M''B',\gamma N}(p,q), \quad (16)
\]

\[
t_{M'B',\gamma N}^R(k',q;W) = \sum_{n,m} \bar{\Gamma}_{M'B',N^*_n}(k';W)[D(W)]_{n,m}\bar{\Gamma}_{N^*_n,\gamma N}(q;W), \quad (17)
\]

\[
\bar{\Gamma}_{N^*,\gamma N}(q;W) = \Gamma_{N^*,\gamma N}(q) + \sum_{M'B'} \int p^2 dp \Gamma_{N^*,M'B'}(p)G_{M'B'}(p;W)t_{M'B',\gamma N}(p,q;W). \quad (18)
\]

Here \(v_{MB,\gamma N}\) is the meson-exchange potential for the \(\gamma N \rightarrow MB\) processes, and \(\bar{\Gamma}_{N^*,\gamma N}(q;W)\) is the dressed \(\gamma N \rightarrow N^*\) vertex (Fig. 3). The procedures for calculating \(v_{MB,\gamma N}\) are detailed in Ref. [1] and also given here in Appendix D. In the latter, the ingredients associated with KY channels are newly added.

For the bare \(\gamma N \rightarrow N^*\) vertex, we depart from the simple parameterization given in Ref. [1] and write it in the helicity representation as

\[
\Gamma_{N^*,\gamma N}(q) = \frac{1}{(2\pi)^{3/2}} \sqrt{\frac{m_N}{E_N(q)}} \sqrt{\frac{q_R}{q_0}} A^{N^*}_\lambda \delta_{\lambda,(\lambda_N)}, \quad (19)
\]

where \(\lambda_{\gamma} (\lambda_N)\) is the helicity quantum number of the photon (nucleon), \(q_R\) and \(q_0\) are defined by \(M_{N^*} = q_R + E_N(q_R)\) and \(W = q_0 + E_N(q)\), respectively. The helicity amplitudes \(A^{N^*}_\lambda\) in the above equation are related to the multipole amplitudes \(E^{N^*}_{l\pm}\) and \(M^{N^*}_{l\pm}\) of \(\gamma N \rightarrow N^*\) processes as

\[
A^{N^*}_{3/2} = \frac{\sqrt{l(l+2)}}{2} [-M^{N^*}_{l+} + E^{N^*}_{l+}], \quad (20)
\]

\[
A^{N^*}_{1/2} = -\frac{1}{2} [lM^{N^*}_{l+} + (l+2)E^{N^*}_{l+}], \quad (21)
\]
for \( \lambda = l + \frac{1}{2} \), and

\[
A_{3/2}^{N^*} = \frac{\sqrt{(l-1)(l+1)}}{2} [M_{l-}^{N^*} + E_{l-}^{N^*}], \tag{22}
\]

\[
A_{1/2}^{N^*} = -\frac{1}{2} [(l+1)M_{l-}^{N^*} - (l-1)E_{l-}^{N^*}], \tag{23}
\]

for \( \lambda = l - \frac{1}{2} \). The multipole amplitudes are parameterized as

\[
M_{l\pm}^{N^*}(q) = \left( \frac{q}{m_\pi} \right)^l \left( \frac{(\Lambda_{N^*}^{e.m.})^2 + m_\pi^2}{(\Lambda_{N^*}^{e.m.})^2 + q^2} \right)^{(2+l)/2} \tilde{M}_{l\pm}^{N^*}, \tag{24}
\]

\[
E_{l\pm}^{N^*}(q) = \left( \frac{q}{m_\pi} \right)^{(l\pm1)} \left( \frac{(\Lambda_{N^*}^{e.m.})^2 + m_\pi^2}{(\Lambda_{N^*}^{e.m.})^2 + q^2} \right)^{[2+(l\pm1)/2]} \tilde{E}_{l\pm}^{N^*}, \tag{25}
\]

where the cutoff \( \Lambda_{N^*}^{e.m.} \) and the coupling constants \( \tilde{M}_{l\pm} \) and \( \tilde{E}_{l\pm} \) are determined in fitting the data. One significant difference between this work and our previous analysis \[3\] is that the multipole amplitudes, or equivalently the helicity amplitudes, for the \( \gamma N \rightarrow N^* \) processes now have momentum dependence. To compare with our previous works \[15\] on \( \Delta(1232) \), however, we depart from the above parameterization and use the following forms for the 1st bare state in \( P_{33} \),

\[
A_{3/2}^{1P_{33}} = -x_{A_{3/2}} \frac{\sqrt{3}}{2} A \left[ G_M^{SL}(0) - (1 - N)G_E^{SL}(0) \right], \tag{26}
\]

\[
A_{1/2}^{1P_{33}} = -x_{A_{1/2}} \frac{1}{2} A \left[ G_M^{SL}(0) - (1 + N_2)G_E^{SL}(0) \right], \tag{27}
\]

with

\[
A = e^{-q} \frac{q}{2m_N} \sqrt{\frac{M_N^*}{m_N}} \sqrt{\frac{E_N(q_R)}{E_N(q)}} \sqrt{\frac{W^2 - m_N^2}{M_N^* - m_N^2}} \frac{W + m_N}{M_N^* + m_N}, \tag{28}
\]

\[
N = 2 \left( \frac{W - m_N}{M_N^* - m_N} \right)^2, \tag{29}
\]

where \( G_M^{SL}(0) = 1.85 \) and \( G_E^{SL}(0) = 0.025 \) \[15\]. The factors \( x_{A_{3/2}} \) and \( x_{A_{1/2}} \) in Eqs. \[26\] and \[27\] are treated as free parameters in our fitting processes.

### III. Extractions of Nucleon Resonances

We follow the earlier works \[38, 39\] to define that a nucleon resonance with a complex mass \( M_R \) is an “eigenstate” of a Hamiltonian \( H|\psi_{N^*}^R\rangle = M_R|\psi_{N^*}^R\rangle \) under the so-called outgoing boundary condition. Then from the spectral expansion of the Low Equation for reaction amplitude \( T(W) = H' + H'(W - H)^{-1}H' \), where we have defined \( H' = H - H_0 \) with \( H_0 \) being the non-interacting free Hamiltonian, we have

\[
T_{M'B',MB}(k_{0M'B'}^0, k_{0MB}^0; W \rightarrow M_R) = \frac{\langle k_{0M'B'}^0|H'|\psi_{N^*}^R\rangle \langle \psi_{N^*}^R|H'|k_{0MB}^0 \rangle}{W - M_R} + \cdots, \tag{30}
\]
where \( k_{MB}^{0} \) and \( k_{M'B'}^{0} \) are the on-shell momenta defined by

\[
W = E_{M}(k_{MB}^{0}) + E_{B}(k_{MB}^{0}) = E_{M'}(k_{M'B'}^{0}) + E_{B'}(k_{M'B'}^{0}).
\]

Therefore the resonance masses \( M_{R} \) can be defined as the pole positions of the meson-baryon amplitude \( T_{M'B',MB}(k_{M'B'},k_{MB}^{0};W) \) on the complex Riemann \( W \)-surface. Because of the quadratic relation between the energy and momentum variables, each \( MB \) channel for a given \( W \) has a physical \((p)\) sheet characterized by \( \text{Im}(k_{MB}^{0}) > 0 \) and an unphysical \((u)\) sheet by \( \text{Im}(k_{MB}^{0}) < 0 \). Like all previous works, we only look for the poles close to the physical region and/or having large effects on scattering observables. All of these poles are on the unphysical sheet of the \( \pi N \) channel, but could be on either \((u)\) or \((p)\) sheets of other channels. To find the resonance poles, we analytically continue Eqs. (3)-(12) to \( \text{Eq. (10)} \). Explicitly, as the energy approaches a resonance position in the complex \( W \)-plane, the total meson-baryon amplitudes can be written as

\[
\text{Eqs. (3)-(12) to complex } W \text{-plane by using the method detailed in Refs. [8, 9]. The main step is to choose appropriate momentum-integration paths in solving Eqs. (3)-(12).}
\]

As derived in Refs. [8, 9], we can write Eq. (30) in terms of \( t_{M'B',MB}(k',k;W) \) that is the solution of Eq. (11), \( t_{M'B',MB}(k',k;W) \) defined by Eq. (8), and \( \bar{\Gamma}_{MB,N^{*}} \) [\( \bar{\Gamma}_{N^{*},MB} \)] by Eq. (9) [Eq. (10)]. Explicitly, as the energy approaches a resonance position in the complex \( W \)-plane, the total meson-baryon amplitudes can be written as

\[
T_{M'B',MB}(k_{M'B'},k_{MB}^{0},W \rightarrow M_{R}) = \bar{B}_{M'B',MB}(M_{R}) + \frac{\bar{R}_{M'B',MB}(M_{R})}{W - M_{R}}, \tag{32}
\]

where the on-shell momenta \( k_{MB}^{R} \) and \( k_{M'B'}^{R} \) are defined by Eq. (31) with \( W = M_{R} \), and

\[
\bar{B}_{M'B',MB}(M_{R}) = t_{M'B',MB}(k_{M'B'},k_{MB}^{R},M_{R}) + \frac{d}{dW} [(W - M_{R})t_{M'B',MB}(k_{M'B'},k_{MB}^{R};W)]_{W=M_{R}}, \tag{33}
\]

\[
\bar{R}_{M'B',MB}(M_{R}) = \bar{\Gamma}_{MB,N^{*}}^{R}(k_{MB}^{R},M_{R}) \bar{\Gamma}_{MB}^{R}(k_{MB}^{R},M_{R}), \tag{34}
\]

with

\[
\bar{\Gamma}_{MB}^{R}(k_{MB}^{R},M_{R}) = \sum_{i} \chi_{i} \bar{\Gamma}_{MB,N^{*}}(k_{MB}^{R},M_{R}). \tag{35}
\]

Here \( \chi_{i} \) represents \( i \)-th 'bare' resonance component of the dressed \( N^{*} \) and satisfies

\[
\sum_{j} \left[D^{-1}(M_{R})\right]_{ij} \chi_{j} = \sum_{j} [(M_{R} - M_{N^{*}j}) \delta_{ij} - \Sigma(M_{R})\delta_{ij}] \chi_{j} = 0. \tag{36}
\]

If there is only one bare \( N^{*} \) state, with \( D^{-1}(W) = W - M_{N^{*}} - \Sigma(W) \), it is easy to see that

\[
\chi = \frac{1}{\sqrt{1 - \Sigma'(M_{R})}}, \tag{37}
\]

where \( \Sigma'(M_{R}) = [d\Sigma/dW]_{W=M_{R}} \).

With the normalizations we employ, the S-matrix in each partial wave is related to \( T_{M'B',MB}(k_{M'B'},k_{MB}^{0};W) \) by

\[
S_{M'B',MB}(W) = \delta_{M'B',MB} - 2iF_{M'B',MB}(W), \tag{38}
\]

where

\[
F_{M'B',MB}(W) = [\rho_{M'B'}(W)]^{1/2}T_{M'B',MB}(k_{M'B'},k_{MB}^{0};W)[\rho_{MB}(W)]^{1/2}, \tag{39}
\]

10
with

$$\rho_{MB}(W) = \frac{\pi k_{0}^{MB} E_{M}(k_{0}^{MB}) E_{B}(k_{0}^{MB})}{W}. \quad (40)$$

For the later use, we denote the residue of the scattering amplitude $F_{M'B',MB}(W)$ at a resonance pole as $R_{M'B',MB}$,

$$F_{M'B',MB}(W \rightarrow M_{R}) = \frac{S_{M'B',MB}(W \rightarrow M_{R}) - \delta_{M'B',MB}}{2i} = - \left[ \frac{R_{M'B',MB}}{W - M_{R}} \right]_{W \rightarrow M_{R}}. \quad (41)$$

From Eqs. (32), (34), (38)-(39), and (41) we have

$$R_{M'B',MB} = [\rho_{M'B'}(W)]^{1/2} \tilde{\Gamma}_{M'B'}^{R}(k_{0}^{R_{M'B'},M_{R}}) \tilde{\Gamma}_{MB}^{R}(k_{0}^{R_{MB},M_{R}})[\rho_{MB}(W)]^{1/2}. \quad (42)$$

The $\pi N$ elasticity of a resonance is then defined as

$$\eta_{e} = \frac{|R_{\pi N,\pi N}|}{-\text{Im}(M_{R})}. \quad (43)$$

With a similar procedure, we have the helicity amplitudes of $\gamma N \rightarrow N^{*}$ at the resonance pole $M_{R}$ as [9]

$$A_{3/2} = C \times \tilde{\Gamma}_{N}^{R}(M_{R}, \lambda_{\gamma} = 1, \lambda_{N} = -1/2), \quad (44)$$
$$A_{1/2} = C \times \Gamma_{N}^{R}(M_{R}, \lambda_{\gamma} = -1, \lambda_{N} = -1/2), \quad (45)$$

where $\lambda_{N}$ and $\lambda_{\gamma}$ are the helicities of the initial nucleon and photon, respectively, and

$$C = \sqrt{\frac{E_{N}(q_{0})}{m_{N}}} \frac{1}{\sqrt{2K}} \sqrt{\frac{(2J_{R} + 1)(2\pi)^{3}(2q_{0})}{4\pi}}, \quad (46)$$

where $J_{R}$ is the spin of the resonance state, $q_{0} = |\vec{q}|$ and $K = (M_{R}^{2} - m_{N}^{2})/(2M_{R})$.

IV. FITTING PROCEDURES

The model parameters specified in Sec. II are determined by fitting the data of pion- and photon-induced $\pi N$, $\eta N$, $K\Lambda$, and $K\Sigma$ production reactions off a proton. One of the difficult tasks in the analysis is to decide the data we fit. For the $\pi N \rightarrow \pi N$ data, we rely on the database of SAID [40]. For simplicity, we fit their single energy solutions of $\pi N$ partial-wave amplitudes instead of fitting the original $\pi N$ elastic scattering data. There is always a question on whether this is a reliable procedure. We justify this by observing that the $\pi N$ partial-wave amplitudes determined by using a very different approach based on the dispersion-relations [41, 42] are not so different from that of SAID. Thus the SAID amplitudes, which are extracted from much more data than the previous analyses, can be considered as fairly reliable representations of the original $\pi N$ elastic scattering data (about 30,000 data points as compiled in SAID).

In this work, we want to determine the spectrum of the $N^{*}$ resonances with masses only up to 2 GeV and widths less than 400 MeV. Since the $N^{*}$ resonances can affect the observables
over the energy range of their widths, we include the data of \( \pi N \rightarrow \pi N \) up to \( W = 2.3 \) GeV to make sure that the \( N^* \) resonances with masses near about 1.9 GeV are properly identified within our model. In Table I we list the data points of the SAID energy-independent solutions included in our fits. In the fitting process, we check the resulting parameters by comparing the predicted observables with the original \( \pi N \) scattering data.

For the data of \( \pi N \rightarrow \eta N, K \Lambda, K \Sigma \) and \( \gamma N \rightarrow \pi N, \eta N, K \Lambda, K \Sigma \), we use the database of Bonn-Gatchina group \[23\] with some differences: (i) we only include the data up to \( W = 2.1 \) GeV; (ii) following the discussion in Ref. \[5\] (the references of the data are also found in Ref. \[5\]), the data for \( \pi p \rightarrow \eta n \) differential cross sections used in our analysis are different from those of Bonn-Gatchina group; and (iii) we include the new data of the polarization \( \Gamma \) of \( \gamma p \rightarrow \pi^0 p \) from CBELSA/TAPS Collaboration \[43\]. The data of \( \pi N \rightarrow \eta N, K \Lambda, K \Sigma \) and \( \gamma N \rightarrow \pi N, \eta N, K \Lambda, K \Sigma \) included in our fit are listed in Tables IV and V. It is known \[44, 54\] that the determinations of the multipole amplitudes of pseudoscalar meson photoproductions need at least 8 observables, i.e., \( d\sigma/d\Omega, \Sigma, T, P \), and appropriately chosen 4 double-spin polarizations. We see from Table V that the polarization observables, in particular the double-spin polarizations, do not have enough data points. Thus it is rather difficult to fit these data since they have much less weights in the \( \chi^2 \)-minimization processes.

We next discuss how we perform the minimization of \( \chi^2 \). We follow the most commonly used definition

\[
\chi^2 = \sum_O \sum_{i,j} \frac{[O_{\text{model}}(W_i, \theta_j) - O_{\text{exp}}(W_i, \theta_j)]^2}{[\delta O_{\text{exp}}(W_i, \theta_j)]^2},
\]

where \( O_{\text{model}}(W_i, \theta_j) \) is the observable \( O \) at energy \( W_i \) and angle \( \theta_j \) calculated from our DCC model, while \( O_{\text{exp}}(W_i, \theta_j) \) and \( \delta O_{\text{exp}}(W_i, \theta_j) \) are the central value and the error of the experimental data, respectively. (Note that the \( \pi N \) partial-wave amplitudes depend only on the energy.) There are more sophisticated minimization procedures accounting for separately the systematic and statistical errors. Thus some of the discrepancies between our final results and the data, as will be presented in the next section, could be partly due to our use of Eq. (47) for \( \chi^2 \). Such a more careful fitting procedure will be desirable when we move to our next analysis including more complete data from future experiments, as will be discussed later.

In the absence of theoretical input, our main challenge is to determine the bare \( N^* \) mass \( M_{N^*}^0 \), the strong \( N^* \rightarrow MB \) bare vertex functions defined by Eq. (14), and the electromagnetic \( N^* \rightarrow \gamma N \) bare vertex functions defined by Eq. (19). For each partial wave, the number of the \( N^* \) parameters contained is \( N_{N^*} \times (3 + N_{c.c.}^{\text{str.}} + N_{c.c.}^{\text{e.m.}}) \). Here \( N_{N^*} \) is the number of the bare \( N^* \) states included in the partial wave, and the number in the parentheses are that of the parameters each bare \( N^* \) state has: 3 comes from the bare mass \( M_{N^*}^0 \), and the cutoffs \( \Lambda_{N^*}^0 \) and \( \Lambda_{N^*}^{\text{e.m.}} \) of the hadronic and electromagnetic decay vertex functions, and \( N_{c.c.}^{\text{str.}} \) (\( N_{c.c.}^{\text{e.m.}} \)) is the number of coupling constants of the hadronic (electromagnetic) interactions, which can be \( 5 \leq N_{c.c.}^{\text{str.}} \leq 10 \) (\( N_{c.c.}^{\text{e.m.}} = 1 \) or 2). We thus face a many-parameters problem in fitting the data, which is also present in all existing coupled-channels analysis of nucleon resonances. This common problem poses difficulties in assigning the errors for the determined model parameters.

Here we have additional difficulties due to the long computation time in solving the coupled-channels integral equations (14), as mentioned in the previous sections. We thus follow all previous works on dynamical model analyses and will not try to resolve this difficult problem here. We therefore are not able to provide the errors of the determined resonance parameters. This must be improved in future.

Due to the many-parameters problem mentioned above and the limitation of the current computation power in the $\chi^2$-minimization, it is practically not possible to get convergent results if all of the model parameters are allowed to vary simultaneously in the $\chi^2$-minimization processes. We therefore take the following strategy. First we determine the parameters associated with the meson-exchange potentials $v_{MB,M'B'}$ to some extent. The parameters associated with the bare $N^*$ states are then determined. In the latter step the parameters of $v_{MB,M'B'}$ may be varied only when it is necessary to fine tune the fits. This two-step procedure is essential since the most time-consuming part of the computation is to calculate the meson-exchange amplitude $t_{MB,M'B'}$ from the meson-exchange potentials $v_{MB,M'B'}$ by solving the coupled-channels equations [1]. Hence the computation time is drastically increased if the parameters of $v_{MB,M'B'}$ are varied in the $\chi^2$-minimization processes.

Concretely, our fitting procedure is as follows. Guided by the success of the meson-exchange models [12, 20] in the $\Delta(1232)$ region, we first adjust the parameters associated with the meson-exchange potentials $v_{M'B',MB}$ to fit the data of the $\pi N$ partial-wave amplitudes at low energies with $W \leq 1.4$ GeV, where one bare $N^*$ state in the $P_{33}$ partial wave is included to incorporate the $\Delta(1232)$ contribution. Fortunately, we find that most

of the parameters in $v_{M'B',MB}$ are heavily constrained by the $\pi N$ partial-wave amplitudes at low energies and do not have to be varied too much in the later fitting processes. Once a good $\pi N$ partial-wave amplitudes in the $W \leq 1.4$ GeV region is obtained, we extend the fits of the amplitudes to $W = 2.3$ GeV by including the bare $N^*$ states in each partial wave. To minimize the number of the bare $N^*$ states, we first include only one bare $N^*$ state in each partial wave and try to fit the data of the $\pi N$ partial-wave amplitudes in the entire considered energy region by adjusting its bare mass, $M_{N^*}^0$, and vertex function parameters, $C_{N^*,MB(\text{LS})}$ and $\Lambda_{N^*}$. If this fails, we then also allow the parameters associated with $v_{MB,M'B'}$ to vary in some limited ranges. If this fails again, we then include one more bare $N^*$ state in some partial waves and repeat the process. After completing the fit of the $\pi N$ partial-wave amplitudes, we extend our global fit step by step: first include the $\pi N$ reaction data of Table [IV] and then include the $\gamma N$ reaction data of Table [V]. This procedure has to be repeated many times to make sure that we have reached the limitation of the model in the $\chi^2$-minimization. The resulting masses, coupling constants, and cutoff parameters for the meson-exchange potentials are given in Tables [XI-XIII]. We find that the considered data can be fitted to a very large extent with one or two bare $N^*$ states in each partial wave. All the resulting cutoff parameters are in the range of 500-2000 MeV, which are similar to those in typical meson exchange models [12–20].

As seen in Tables [III,V], the numbers of the data points of each reaction are very different. The observables with much less data points are hard to fit because they have little effects on $\chi^2$-minimization. Thus during the fitting processes, we need to include “artificial” weights for those observables in Eq. (47). This procedure, which is highly undesirable, is however necessary before those data become more extensive. Also for this reason, we cannot give meaningful $\chi^2$ values. To show the quality of our fits, in the next section we present detailed comparisons with the data for all processes considered. Hopefully, the situation, in particular the scarce data for the pion-induced inelastic reactions, can be improved with new experiments at J-PARC.
V. RESULTS

In this section we present the results from our fits to 22,348 data points listed in Tables III-V. The resulting values of the model parameters are presented in Tables XI-XVI of Appendix E. The formulas for calculating the considered observables of the $\pi N, \gamma N \rightarrow \pi N, \eta N, K\Lambda, K\Sigma$ from the partial-wave amplitudes defined in Sec. III can be straightforwardly derived following the formulas given in Refs. [1, 44] and will not be given here. Here it should be noted that in the literature various notations have been employed for the polarization observables of pseudoscalar photoproduction reactions (see Ref. [45] for the summary of such notations used by different analysis groups). In this work, we follow the notation defined in Ref. [44]. In the following subsections, we discuss separately the results for each considered reaction.

A. $\pi N \rightarrow \pi N$

In Figs. 4 and 5, we present our results for the $\pi N \rightarrow \pi N$ partial-wave amplitudes up to $W = 2.3$ GeV. Clearly, very good fits to the data of SAID [40] have been obtained. Comparing with the green dotted curves of our previous analysis (JLMS) [2], which were obtained by the fit to the data of the $\pi N$ amplitudes only up to $F$-wave ($L = 3$) and $W = 2$ GeV, there are significant improvements in the $S_{31}, P_{31}, D_{35}$ partial waves, as seen in Fig. 5. The large improvement in the $P_{31}$ and $D_{35}$ waves in this analysis is mainly because we have introduced more bare $N^*$ states than JLMS for those partial waves. These improvements are also perhaps due to the change of our fitting strategy by using the data below 1.4 GeV to constrain the parameters of the meson-exchange potentials $v_{MB,MB'}$. We also find that this procedure prevents the model from generating undesirable bound states through the strong coupling with the bare $N^*$ states in the low energy region. We also note that the data of the $G$ and $H$ partial waves with the orbital angular momentum $L \geq 4$, which were not included in the fit of JLMS, are also fitted very well. These high-$L$ partial waves become important in fitting the meson production data in the high $W$ region.

To test our model directly with the experimental data, we have also calculated the observables of $\pi N$ scattering. Some results of the predicted $\pi N$ elastic scattering observables are shown in Figs. 6 and 7. Clearly good agreements have been obtained. Thus our model parameters are consistent with the $\sim 30,000$ data points of $\pi N$ scattering compiled in SAID.
FIG. 4. (Color online) Partial-wave amplitudes of πN scattering with isospin $I = 1/2$. Upper (lower) panels are for real (imaginary) parts of the amplitudes. (Red solid curves) current results; (green dotted curves) results from our previous analysis [2].
FIG. 5. (Color online) Partial-wave amplitudes of $\pi N$ scattering with isospin $I = 3/2$. Upper (lower) panels are for real (imaginary) parts of the amplitudes. (Red solid curves) current results; (green dotted curves) results from our previous analysis [2].
FIG. 6. (Color online) Differential cross section $d\sigma/d\Omega$ of $\pi N \rightarrow \pi N$. (Red solid curves) current results; (green dotted curves) results from our previous analysis [2]. The corresponding values of $W$ are indicated in each panel. The same applies to the rest of figures.

FIG. 7. (Color online) Target polarization $P$ of $\pi N \rightarrow \pi N$. (Red solid curves) current results; (green dotted curves) results from our previous analysis [2].
B. $\gamma N \rightarrow \pi N$

In our previous analysis [3], we only considered the data of differential cross section $d\sigma/d\Omega$ and photon-asymmetry $\Sigma$ of the $\gamma N \rightarrow \pi N$ reactions. Also, the fits were performed by only adjusting the bare $N^* \rightarrow \gamma N$ parameters, and all other parameters of the model were fixed at the values determined in the fits to the $\pi N \rightarrow \pi N$ data [2]. It was found that only the data below $W = 1.6$ GeV can be fitted well by using such a very restricted procedure. In this work, we allow all of the model parameters to vary to fit simultaneously the data of $\pi N \rightarrow \pi N, \eta N, K\Lambda, K\Sigma$ and $\gamma N \rightarrow \pi N, \eta N, K\Lambda, K\Sigma$. This change of the fitting strategy gives us more freedom to fit the data at higher energies above 1.6 GeV and other polarization observables comprehensively.

The $\gamma N \rightarrow \pi N$ data included in our fits are listed in the first two rows of Table V. We see that the data points of $d\sigma/d\Omega$ and $\Sigma$ of $\gamma p \rightarrow \pi^0 p$ are much more than those for the other considered pion photoproduction observables. Thus these two data sets have similar large weights in determining the parameters in our coupled-channels analysis. In Figs. 8-11, we see that these rather extensive data below about $W = 1.9$ GeV can be fitted very well. We however are not able to account for the forward peaks in $d\sigma/d\Omega$ at $W \geq 1.933$ GeV. Similar difficulty is also encountered in fitting the data of $\Sigma$ at $W \gtrsim 1.9$ GeV. We expect that such data in the forward-angle region are affected mainly by the $t$-channel processes rather than the $s$-channel resonance ones. This might suggest a need for an incorporation of Regge-type processes at high energies.

The fits to the other polarization observables, $P, T, \hat{E}, G, H$, of $\gamma p \rightarrow \pi^0 p$ are shown in Figs. 12-15. (Note that the beam-target polarization $\hat{E}$ defined in Ref. [44] and the quantity $\Delta_{31}$ measured and presented in Ref. [46], which are used as the data in our fits, are related with each other by $\hat{E} = -(1/2)\Delta_{31}$.) As seen in Table V the numbers of these data points are much less than those of $d\sigma/d\Omega$ and $\Sigma$, it is therefore not easy to improve the fits to these polarization observables, in particular $\hat{E}, G, H$ (Figs. 14 and 15). While we need to improve our fits, more precise data of the polarization observables are also needed to make further progress.

Our fits to the data of $d\sigma/d\Omega$ of $\gamma p \rightarrow \pi^+ n$ are shown in Figs. 16 and 17. The fits are good in most of the considered energy region. The data at forward angles in the $W \gtrsim 1.8$ GeV region cannot be accounted for. The origin of this difficulty is perhaps related to the similar problem in $d\sigma/d\Omega$ for $\gamma p \rightarrow \pi^0 p$. Our fits to the polarization observables of $\gamma p \rightarrow \pi^+ n$ become less accurate as $W$ increases, as seen in Figs. 18-23.

Overall, we are able to fit more data of $\gamma p \rightarrow \pi^0 p, \pi^+ n$ than the JLMS analysis [3]. Not only we cover the $W \geq 1.6$ GeV region, our fits to the data in the low energy region with $W \leq 1.2$ GeV are much better. We however still cannot fit accurately the data in the $W$ region close to 2.0 GeV. Here we note that in this high-$W$ region, the data for the $\eta N, K\Lambda$, and $K\Sigma$ channels play a very significant role in the analysis through the coupled-channels effects. Thus the discrepancies with the data in the high-$W$ region cannot be trivially removed.

C. $\pi^- p \to \eta n$

The $\pi^- p \to \eta n$ is simpler than $\pi N$ elastic scattering since it depends only on the isospin $I = 1/2$ partial waves. As mentioned in Sec. IV, the data for this reaction used in our fits are chosen carefully according to the discussion in Ref. [5] because some inconsistency exists among the data sets from different experiments. In Fig. 24, we show our fits to the data of $d\sigma/d\Omega$ data of $\pi^- p \to \eta n$. Clearly, our results reproduce the considered $d\sigma/d\Omega$ data well.

![Graph showing $\pi^- p \to \eta n$ data and fits](image)

FIG. 24. (Color online) $d\sigma/d\Omega$ of $\pi^- p \to \eta n$.

D. $\gamma p \to \eta p$

Our fits to the data of $\gamma p \to \eta p$ up to $W = 2.1$ GeV are shown in Figs. 25-28. Clearly, both the differential cross sections $d\sigma/d\Omega$ and the polarization observables $\Sigma$ and $T$ can be described well in the considered energy region. Our results for $\Sigma$ above $W = 1.7$ GeV are smaller than the data in the $0^\circ \lesssim \theta \lesssim 90^\circ$ region, although the positive values of the data are reproduced to a large extent.

FIG. 27. (Color online) $\Sigma$ of $\gamma p \rightarrow \eta p$.

FIG. 28. (Color online) $T$ of $\gamma p \rightarrow \eta p$. 
E. $\pi^+ p \to K^+ \Sigma^+$

The $\pi^+ p \to K^+ \Sigma^+$ reaction depends only on the isospin $I = 3/2$ partial waves, and hence the $I = 1/2$ $N^*$ states cannot contribute. Our fits to both $d\sigma/d\Omega$ and $P$ up to $W = 2106$ MeV are good, as shown in Figs. 29 and 30. In Fig. 31 we present the spin-rotation $\beta$. This quantity is modulo $2\pi$, and here we plot it in the range $[-\pi, \pi]$. At present, almost no data is available for $\beta$ of this reaction and these few data points hardly affect the $\chi^2$-minimization. We thus are not able to improve our results shown in Fig. 31.
F. $\pi^- p \rightarrow K^0 \Lambda^0$

In contrast with the $\pi^+ p \rightarrow K^+ \Sigma^+$ discussed in the above subsection, the $\pi^- p \rightarrow K^0 \Lambda^0$ only involves the isospin $I = 1/2$ mechanism. Our fits to $d\sigma/d\Omega$ and $P$ of this reaction are shown in Figs. 32 and 33, respectively. Clearly, our fits are very good. Our results for the spin rotation $\beta$ reproduce the main feature of the data while these few data points, like those in the $\pi^+ p \rightarrow K^+ \Sigma^+$ reaction, have practically no effect in the $\chi^2$-minimization. More data for $\beta$ will be necessary to improve the situation.

![Image of Fig. 34: $\beta$ for $\pi^- p \rightarrow K^0 \Lambda^0$.](image)

**FIG. 34.** (Color online) $\beta$ of $\pi^- p \rightarrow K^0 \Lambda^0$.
G. $\pi^- p \to K^0 \Sigma^0$

The $\pi^- p \to K^0 \Sigma^0$ reaction is more complex than $\pi^+ p \to K^+ \Sigma^+$ and $\pi^- p \to K^0 \Lambda^0$, since it involves interfering contributions from both the isospin $I = 1/2$ and $I = 3/2$ mechanisms. Our fits to the data of $d\sigma/d\Omega$ and $P$ of this reaction are shown in Figs. 35 and 36 respectively. We see that our results reproduce the data to a large extent in the considered energy region, although the $d\sigma/d\Omega$ data in the near threshold region are underestimated.

Here we note that all of the $\pi N \to KY$ data used in our fits are from old measurements more than a quarter of century ago. Their statistical errors are in general quite large compared with the recent photoproduction data. Furthermore, amount of the data is scarce in the kinematical region relevant to $N^*$ above 1.6 GeV, in particular for the $\pi^- p \to K^0 \Sigma^0$ reaction. An experiment planned at J-PARC [47] is quite encouraging, where the high precision data for $\pi N \to \pi\pi N$ and $\pi N \to KY$ will be obtained in the wide energy region.

![FIG. 35. (Color online) $d\sigma/d\Omega$ of $\pi^- p \to K^0 \Sigma^0$.](image)

![FIG. 36. (Color online) $P$ of $\pi^- p \to K^0 \Sigma^0$.](image)
Our fits to the $d\sigma/d\Omega$ data of $\gamma p \rightarrow K^+\Lambda$ are shown in Figs. 37 and 38. The main features of the data up to $W = 2106$ MeV are reproduced reasonably well, in particular in the $45^\circ \lesssim \theta \lesssim 135^\circ$ region where the s-channel processes with the isospin $I = 1/2$ $N^*$ resonances are found to be important. However, our results at forward and backward angles underestimate the data in the $W \gtrsim 1.9$ GeV high energy region. This situation is similar to the $\gamma p \rightarrow \pi N$ reactions and further suggests that the inclusion of additional mechanisms would be necessary for improving our combined analysis at high energies.

Because of the self-analyzing property of the recoil $\Lambda$ baryon, the single and double polarization observables of $\gamma p \rightarrow K^+\Lambda$ have been extensively measured in recent years. More data of the polarization observables of $\gamma p \rightarrow K^+\Lambda$ will soon become available from JLab and other photon/electron beam facilities. Actually, all the possible 15 polarization observables for this reaction have already been measured at CLAS [48].

The fits to the available polarization data, as listed in Table V, are already highly non-trivial since they are due to delicate interferences between different partial waves. Nevertheless, as seen in Figs. 39 and 40, our fits can reproduce the main features of these polarization data to a very large extent. Here it is noted that for the double polarizations $C_x$ and $C_z$, we have plotted them in the *primed* coordinate system as $C_x'$ and $C_z'$, by using the relation

$$C_x' = +C_x \cos \theta - C_z \sin \theta,$$

$$C_z' = +C_x \sin \theta + C_z \cos \theta,$$

as done in the analysis of Ref. [44].

I. $\gamma p \to K^+ \Sigma^0, K^0 \Sigma^+$

It is more difficult to fit the data of $\gamma p \to K^+ \Sigma^0$ and $\gamma p \to K^0 \Sigma^+$ than that of $\gamma p \to K^+ \Lambda^0$ presented in the previous subsection, since here the isospin $I = 3/2$ $N^*$ resonances also contribute. In particular, we have found that the $d\sigma/d\Omega$ data for both $\gamma p \to K^+ \Sigma^0$ and $\gamma p \to K^0 \Sigma^+$ can be fitted well only when the $K \Sigma N$ coupling constant $g_{K \Sigma N}$ is allowed to vary far off the SU(3) relation, as given in Eqs. (B31), in the fits. This implies that $\gamma p \to K \Sigma$ reaction could be an important source of learning about the validity of the SU(3) relation. This however can be done rigorously only when more complete data for these two photoproduction reactions become available.

Our fits to the data of differential cross sections $d\sigma/d\Omega$ and polarization observables $P$, $\Sigma$, $C_x$, $C_z$ of $\gamma p \to K^+ \Sigma^0$ are shown in Figs. 41-43. Again we have plotted $C_x$ and $C_z$ as $C_x'$ and $C_z'$ in the primed coordinate system using Eqs. (49) and (49). We see that the fits to the data of differential cross sections (Fig. 41), $P$ and $\Sigma$ (Fig. 42) are fairly good. On the other hand, the fits to the data of $C_x$, $C_z$ (Fig. 43) are very qualitative, in particular in the high energy region, $W \gtrsim 1.8$ GeV.

FIG. 41. (Color online) $d\sigma/d\Omega$ of $\gamma p \to K^+ \Sigma^0$. 
FIG. 42. (Color online) $P$ and $\Sigma$ of $\gamma p \rightarrow K^+\Sigma^0$.

FIG. 43. (Color online) $C_x'$ and $C_z'$ of $\gamma p \rightarrow K^+\Sigma^0$. 
We now present our fits to the very limited data of the $\gamma p \rightarrow K^0\Sigma^+$ reaction in Figs. 44 and 45. Clearly, our fits to the data of $d\sigma/d\Omega$, shown in Fig. 44, are only qualitative in the $W \gtrsim 1.9$ GeV region. On the other hand, we see in Fig. 45 that our fits to the data of $P$ and $\Sigma$ are reasonable.

FIG. 44. (Color online) $d\sigma/d\Omega$ of $\gamma p \rightarrow K^0\Sigma^+$.

VI. RESONANCE PARAMETERS

Once the model parameters are determined by the simultaneous fits to all of the considered data, as presented in Sec. IV, we then apply the analytic continuation method of Refs. [8, 9] to find the resonance pole positions and their residues. We expect that the resonances with large widths [the widths are related to the resonance pole position $M_R$ by $\Gamma^{\text{tot}} = -2\text{Im}(M_R)$] have less influence on the physical observables, and thus the extractions of these resonances from fitting the available reaction data, as done by all analysis groups, are more model-dependent. As a result, the extracted information on those resonances is much less reliable. We therefore examine only the resonances with the width less than 400 MeV. Also, as already mentioned in Sec. IV, the resonances with $\text{Re}(M_R) > 2$ GeV, found in $F_{17}$, $G$ and $H$ waves, will also not be presented here. We will be able to present those high mass resonances with confidence only after extending our analysis to higher energy region and including $\omega N$ and $\pi\pi N$ production data.

As defined in Eqs. (32)-(35), we will present our results for the resonance pole positions $M_R$ and residues $R_{MB,\pi N}(M_R)$ for $MB = \pi N, \eta N, K\Lambda, K\Sigma$. Other components of the extracted residues do not correspond to the reaction data considered, and will not be presented. The elasticity $\eta_e$ [Eq. (133)] and helicity amplitudes $A_{\lambda=1/2,3/2}$ [Eqs. (14) and (15)] will also be presented. Our results are given and discussed in the following subsections.

A. Resonance pole positions and Residues

The $N^*$ pole positions $M_R$ extracted from our analysis are presented in Table VI and compared with those listed by Particle Data Group (PDG). The $N^*$ states are specified by $JP(L_{2121})$, where $J$ is the spin, $P = \pm$ the parity, $I$ the isospin, and $L$ the orbital angular momentum of the associated $\pi N$ partial wave. Here we only list the 3- and 4-stars $N^*$ of PDG since their values are rather stable in the past two decades and most of their widths are all less than 400 MeV that is the limit set in our search. We see that we agree well with PDG for the $N^*$ resonances below 2 GeV except: (a) we do not have a 3rd state in $3/2^-(D_{13})$, (b) we do not have a 3rd state in $3/2^+(P_{33})$, and (c) we have a 2nd state in $3/2^-(D_{33})$. In our analysis, a resonance pole with $M_R = (1429, 147)$ MeV in $1/2^+(P_{11})$ is also found, which turns out to be a “shadow” of the 1st $1/2^+(P_{11})$ resonance with respect to the $\pi\Delta$ branch point. However, this pole is far from the physical region and thus is not listed. Such a shadow pole is also found in other analyses (e.g., Ref. [20]) as well as our early analyses [10, 11]. In the Table VI we also see that the determined elasticities $\eta_e$ are rather consistent with the values listed by PDG.

In Figs. 46 and 47 we compare our (ANL-Osaka) values (AO, 2nd column) of the $N^*$ spectrum with those from PDG (PDG, first column) and the analyses by the Jülich [20] (J, 3rd column) and the Bonn-Gatchina [23] (BG, 4th column) groups. In the figures only the resonances with the total widths less than 400 MeV are compared. It is noted, however, that some broad $N^*$ resonances with $(\text{Re}(M_R), -2\text{Im}(M_R)) = (1787, 575)$ MeV in $1/2^+(P_{31})$, (1727, 866) MeV in $3/2^+(P_{33})$, and (1776, 646) MeV in $5/2^-(D_{35})$ have also been reported by the Jülich group, while $(\text{Re}(M_R), -2\text{Im}(M_R)) = (1660, 450)$ MeV in $3/2^+(P_{13})$, (1770, 420) MeV in $3/2^-(D_{13})$, and (1990, 450) MeV in $3/2^-(D_{33})$ have been reported by the Bonn-Gatchina group.

We see in Figs. 46 and 47 that the first $N^*$ resonances from four results in each $(J^P, I)$ state agree well except: (a) the $3/2^+(P_{13})$ from the Bonn-Gatchina analysis is about 200 MeV
higher than the others, (b) the Jülich analysis does not have 1/2+ (P31), (c) only the Jülich analysis has 7/2+ (F17) below 2 GeV, and (d) the Jülich and Bonn-Gatchina analyses do not have 5/2− (D35). For higher mass states, the number of states and their positions from four results do not agree well. Here we mention that the PDG values are mainly from the earlier results of πN elastic scattering data. The photoproduction data of γp → πN, ηN, KΛ, KΣ have not been included in the Jülich analysis, while the data included in the AO and Bonn-Gatchina analyses are not too different. As discussed in the Introduction, the K-matrix model used in the Bonn-Gatchina analysis is very different from the DCC model used in the AO and Jülich analyses. In the Bonn-Gatchina analysis, like other K-matrix model analyses, the parameters in different partial waves are varied independently in the fits. On the other hand, the parameters of meson-exchange mechanisms in the AO and Jülich analyses are not independent of partial waves and channels. Thus the Bonn-Gatchina analysis is more flexible and efficient in fitting the data; in particular in the area where the data have fluctuating structure with large uncertainties.

Thus the differences between four results seen in Figs. 46 and 47 could be due to the differences in the employed analysis methods and the data included in the analysis. The
FIG. 47. (Color online) $N^*$ spectrum with the isospin $I = 1/2$ determined by ANL-Osaka (AO) collaboration. For each $N^*$ state, Re($M_R$) together with the Re($M_R$) $\pm$ Im($M_R$) band is plotted. The results are compared with 4- and 3-star states listed by the PDG [49] as well as the results from Jülich (J) (model A in Ref. [20]) and Bonn-Gatchina (BG) [23] groups. The spin and parity of states are denoted as $J^P$ with $P = \pm$ and the associated $\pi N$ partial wave.

much more divergent results for the second and third states could also be due to the fact that in the high $W \gtrsim 1.6$ GeV region, the available data are far from complete for determining the partial wave amplitudes model independently. The difficulties in extracting the partial wave amplitudes model independently from the data, even they are complete, have been investigated recently in Ref. [44].

In Table VII we list the extracted residues $R_{MB,\pi N}$ for $MB = \pi N, \eta N, K\Lambda, K\Sigma$. In Table VIII we compare the extracted residues $R_{\pi N,\pi N}$ with those from the Bonn-Gatchina and Jülich analyses. Three analyses agree very well for the well-established $\Delta(1211) \, 3/2^+ (P_{33})$. For some states, three results agree qualitatively. However, the differences between three results can be very different for several states. This is perhaps due to the fact that the residues are more sensitive to the functional forms of the amplitudes which are very different between different analyses. More detailed investigations of this issue are needed for advancing the field, but is beyond the scope of this paper.
TABLE VI. $N^*$ pole mass $M_R$ and $\pi N$ elasticity $\eta_e$ extracted in this work. $M_R$ is listed as $(\text{Re}(M_R), -\text{Im}(M_R))$ in the unit of MeV. As a reference, we also list the PDG values of the $N^*$ states for which either 4- or 3-star status is assigned \[49\]. The $N^*$ states for which the asterisk (*) is marked locate in the complex energy plane slightly off the closest sheet to the physical real energy axis, yet are still expected to visibly affect the physical observables.

B. $\gamma N \rightarrow N^*$ helicity amplitudes

To determine the $\gamma N \rightarrow N^*$ helicity amplitude, we first extract the residue $R_{\pi N, \gamma N}(M_R)$ of the $\gamma N \rightarrow \pi N$ amplitude at the resonance pole position $M_R$. By using Eq. (34) of the factorized form of $R_{\pi N, \gamma N}(M_R)$, the dressed vertex $\Gamma_{\gamma N}(M_R)$ can be determined from the extracted $R_{\pi N, \gamma N}(M_R)$ and the $R_{\pi N, \pi N}(M_R)$ listed in Table VII. The $\gamma N \rightarrow N^*$ helicity amplitudes can then be calculated from the resulting $\Gamma_{\gamma N}$ by using Eqs. (44)-(46).

Our results are listed in Table IX and are compared with those extracted by the Bonn-Gatchina group. We see that two results agree very well for the $\Delta(1211)$. For the $N^*$ resonances with $L \leq 2$ and $\text{Re}(M_R) < 1.7$ GeV, $N(1482) 1/2^- (S_{11})$, $N(1656) 1/2^- (S_{11})$, $N(1374) 1/2^+ (P_{11})$, $N(1500) 3/2^- (D_{13})$, $N(1650) 5/2^- (D_{15})$, and $\Delta(1592) 1/2^- (S_{31})$, some qualitative agreements between the two analyses can be seen. On the other hand, it is difficult to compare the results for other resonance states. Here we note that the phase of
TABLE VII. Residues for $\pi N \rightarrow N^* \rightarrow MB$ amplitudes ($R_{MB,\pi N}$) at the $N^*$ resonance pole position. The listed values of $R_{MB,\pi N}$ are in the unit of MeV. Each resonance is specified by its quantum numbers and the real part of the pole mass $\text{Re}(M_R)$.

$\gamma N \rightarrow N^*$ chosen by different analysis groups can be different, as discussed in Ref. \[50\]. This adds another complications in comparing the results listed in Table IX. We do not compare our results with those from Refs. \[51, 52\], since their results are from the Breit-Wigner parameterization which cannot be related model independently to the residues at resonance pole, as discussed in Ref. \[50\].

VII. SUMMARY AND FUTURE DEVELOPMENTS

We have extended the dynamical coupled-channels model developed in Refs. \[1, 11\] to include the $K\Lambda$ and $K\Sigma$ channels and have completed a combined analysis of the data of $\pi N, \gamma N \rightarrow \pi N, \eta N, K\Lambda, K\Sigma$ reactions. The pole positions and residues of nucleon resonances with masses below 2 GeV and total widths less than 400 MeV have been extracted. From the extracted residues, we have determined the $N^* \rightarrow \gamma N, \pi N, \eta N, K\Lambda, K\Sigma$ transition amplitudes at the resonance positions. How these information can be related to the results from the hadron models and lattice QCD calculations is an important challenge in advancing our understanding of the structure of the nucleon and its excited states. While some progress in this direction has been made \[13, 53\] for the $\Delta(1232) \rightarrow \gamma N$ transitions,
The extracted residues of $\pi N \rightarrow \pi N$ partial-wave amplitudes are compared with Bonn-Gatchina analysis and Jülich analysis. Except for the well-established $\Delta(1232)$ resonance, three analyses agree only qualitatively even for the cases that their pole positions are close. Similar situation is also found in comparing the extracted $N^* \rightarrow \gamma N$ helicity amplitudes with those from the Bonn-Gatchina analysis. This is perhaps due to the fact that the residues are more sensitive to the model or parameterization used in the analyses. It is necessary to clarify this issue for advancing the field.

To improve our analysis in the higher mass region, we need to include the data of much more works are needed.

The $N^*$ masses extracted from our analysis, PDG, Jülich analysis, and Bonn-Gatchina analysis agree well only in the low mass region. In the higher mass region the differences among four results are rather large. This could be mainly due to the fact that in the high $W \gtrsim 1.7$ GeV region, the available data of $\pi N$ and $\gamma N$ reactions are far from complete to determine the partial wave amplitudes model independently. The difficulties in extracting the partial wave amplitudes model-independently from the data, even they are complete, have been investigated in Refs. [44, 54–56]. Of course the differences in the analysis methods and the data included in each analysis could also lead to large disagreements, as discussed in Sec. [V] It is necessary to clarify the situation.

The extracted residues of $\pi N \rightarrow \pi N$ partial-wave amplitudes are compared with Bonn-Gatchina analysis and Jülich analysis. Except for the well-established $\Delta(1232)$ resonance, three analyses agree only qualitatively even for the cases that their pole positions are close. Similar situation is also found in comparing the extracted $N^* \rightarrow \gamma N$ helicity amplitudes with those from the Bonn-Gatchina analysis. This is perhaps due to the fact that the residues are more sensitive to the model or parameterization used in the analyses. It is necessary to clarify this issue for advancing the field.

To improve our analysis in the higher mass region, we need to include the data of
The reaction mechanisms associated with the \( \pi \pi N \rightarrow \pi N, \gamma N \) and \( \rho N \) reactions that dominate the \( \pi N \) and \( \gamma N \) reaction cross sections at \( W \gtrsim 1.6 \) GeV. To proceed, we need detailed data for these two processes. For \( \gamma N \rightarrow \pi N \), the precise data of invariant mass distributions and some polarization observables are becoming available from the facilities such as JLab, Mainz, Bonn, LNS, and SPring-8. For \( \pi N \rightarrow \pi N \), however, what available is only the old data of the total cross sections with rather large uncertainties and very limited invariant mass distributions in the energy region above \( W = 1.6 \) GeV \[3, 24\]. The situation can be improved greatly when the data from the new experiments on \( \pi N \rightarrow \pi N \) reactions at J-PARC \[47\] become available in the near future. To pin down the reaction mechanisms associated with the \( \pi \Delta, \rho N \), and \( \sigma N \) channels, the Dalitz plot data of the \( \pi N \) distributions will be desirable. The importance of fitting the Dalitz plot data has been illustrated recently in Ref. \[57, 58\] for the three-pion decays of heavy mesons. We also need to extend the analysis to include the \( \omega N \) channel which has significant contributions to the \( \pi N \) and \( \gamma N \) reaction cross sections at \( W \gtrsim 1.7 \) GeV. It will be useful if more extensive data of \( \pi N \rightarrow \omega N \) can also be obtained at J-PARC.

Our DCC model developed in this work can be readily applied to the electron- and neutrino-induced meson production reactions. The application to the electroproduction reactions, which corresponds to the extension of our early analysis of \( p(e, e' \pi)N \) \[3\], is crucial.

for determining the $Q^2$ dependence of $N$-$N^*$ electromagnetic transition form factors. This analysis is a key to understanding the quark-gluon substructure of the $N^*$ states \cite{59} and will be closely related to the $N^*$ program at JLab after the 12-GeV upgrade \cite{60}. Also, precise knowledge of the neutrino-nucleon/nucleus reactions in the GeV-energy region is expected to be very important for determining the leptonic $CP$-phase and neutrino-mass hierarchy from the neutrino-oscillation measurements through the accelerator and atmospheric experiments \cite{61}. By following the procedure of Refs. \cite{62,63}, the DCC model presented in this work can be extended straightforwardly to describe the neutrino-induced reactions in the nucleon resonance region. A first attempt to study the neutrino-induced reactions within the current DCC model has been done in Ref. \cite{64}. A further extensive study of the neutrino-induced reactions are ongoing and will be presented elsewhere.

**ACKNOWLEDGMENTS**

The authors thank J. Durand, B. Juliá-Díaz, A. Matsuyama, B. Saghai, L. C. Smith, and N. Suzuki for their collaborations at EBAC, and would also like to thank A. W. Thomas for his strong support and his many constructive discussions. We thank the support from JLab to the development of the first stage of this analysis as reported in Ref. \cite{65}. This work was supported by the JSPS KAKENHI Grant Numbers 24540273 and 25800149, and by the U.S. Department of Energy, Office of Nuclear Physics Division, under Contract No. DE-AC02-06CH11357. HK acknowledges the support by the HPCI Strategic Program (Field 5 “The Origin of Matter and the Universe”) of Ministry of Education, Culture, Sports, Science and Technology (MEXT) of Japan. SXN is the Yukawa Fellow and his work is supported in part by Yukawa Memorial Foundation, the Yukawa International Program for Quark-hadron Sciences (YIPQS), and by Grants-in-Aid for the global COE program “The Next Generation of Physics, Spun from Universality and Emergence” from MEXT. This research used resources of the National Energy Research Scientific Computing Center, which is supported by the Office of Science of the U.S. Department of Energy under Contract No. DE-AC02-05CH11231, and resources provided on “Fusion,” a 320-node computing cluster operated by the Laboratory Computing Resource Center at Argonne National Laboratory.

**Appendix A: Self-energies in meson-baryon Green functions**

In this Appendix, we give an explicit expression of the self-energy $\Sigma_{MB}(k; W)$ appearing in the meson-baryon Green function [Eq. \cite{47}] for the unstable channels $MB = \pi\Delta, \rho N, \sigma N$. As for the $\pi\Delta$ and $\rho N$ channels, the self energies are explicitly given by

\begin{align}
\Sigma_{\pi\Delta}(k; W) &= \frac{m_{\Delta}}{E_{\Delta}(k)} \int_{C_3} q^2 dq \frac{M_{\pi N}(q)}{[M_{\pi N}(q) + k^2]^{1/2}} \frac{|f_{\Delta\rightarrow\pi N}(q)|}{W - E_{\pi}(k) - [M_{\pi N}(q) + k^2]^{1/2} + i\epsilon}, \tag{A1} \\
\Sigma_{\rho N}(k; W) &= \frac{m_{\rho}}{E_{\rho}(k)} \int_{C_3} q^2 dq \frac{M_{\pi\pi}(q)}{[M_{\pi\pi}(q) + k^2]^{1/2}} \frac{|f_{\rho\rightarrow\pi\pi}(q)|}{W - E_{\pi}(k) - [M_{\pi\pi}(q) + k^2]^{1/2} + i\epsilon}, \tag{A2}
\end{align}

where $m_{\Delta} = 1280$ MeV, $m_{\rho} = 812$ MeV, $M_{\pi N}(q) = E_{\pi}(q) + E_{N}(q)$, and $M_{\pi\pi}(q) = E_{\pi}(q) + E_{\pi}(q)$. The form factors $f_{\Delta\rightarrow\pi N}(q)$ and $f_{\rho\rightarrow\pi\pi}(q)$ are for describing the $\Delta \rightarrow \pi N$ and $\rho \rightarrow \pi\pi$ transitions.
decays in the $\Delta$ and $\rho$ rest frames, respectively. Those are parameterized as \[ f_{\Delta \to \pi N}(q) = \frac{(0.98)}{[2(m_N + m_\pi)]^{1/2}} \left( \frac{q}{m_\pi} \right) \left( \frac{1}{1 + [q/(358 \text{ MeV})]^2} \right)^2, \] \[ f_{\rho \to \pi \pi}(q) = \frac{(0.6684)}{\sqrt{m_\pi}} \left( \frac{q}{461 \text{ MeV}} \right) \left( \frac{1}{1 + [q/(461 \text{ MeV})]^2} \right)^2. \] \[ \text{(A3)} \]

To construct the $\sigma$ self-energy in the $\sigma N$ Green function, $\Sigma_{\sigma N}(k; W)$, we first consider a $\pi\pi$ scattering model for the isospin $I = 0$ and s-wave, described by the following separable potential in the $\pi\pi$ center-of-mass system,

\[ v(p', p; E) = g(p') \frac{1}{E - m_\sigma - i\varepsilon} g(p) + h_0 h(p') h(p). \] \[ \text{(A5)} \]

Here $p$ and $p'$ are the magnitude of the initial and final momentum; $E$ is the total scattering energy in the $\pi\pi$ system; and the form factors are parameterized as

\[ g(p) = \frac{g_0}{\sqrt{m_\pi}} \frac{1}{1 + (cp)^2}, \] \[ h(p) = \frac{1}{m_\pi} \frac{1}{1 + (dp)^2}. \] \[ \text{(A6)} \text{(A7)} \]

With this potential, one can solve the Lippmann-Schwinger equation to obtain the $\pi\pi$ scattering amplitude $T$. The solution is expressed as

\[ T = t + t^R, \] \[ \text{(A8)} \]

where $t$ is the “non-resonant” part of the amplitude given by

\[ t(p', p; E) = h(p') \tau(E) h(p), \] \[ \tau(E) = \frac{h_0}{1 - h_0 \langle h G_{\pi\pi} h \rangle(E)}, \] \[ \langle h G_{\pi\pi} h \rangle(E) = \int dq q^2 h(q) \frac{1}{E - M_{\pi\pi}(q) + i\varepsilon} h(q), \] \[ \text{(A9)} \text{(A10)} \text{(A11)} \]

while $t^R$ the “resonant” part given by

\[ t^R(p', p; E) = \frac{\bar{\Gamma}_{\sigma \to \pi\pi}(p'; E) \bar{\Gamma}_{\pi\pi \to \sigma}(p; E)}{E - m_\sigma - \Sigma_{\sigma}(E)}. \] \[ \text{(A12)} \]

The $\sigma$ self-energy $\Sigma_{\sigma}(E)$ and the dressed $\sigma \to \pi\pi$ vertex $\bar{\Gamma}_{\sigma \to \pi\pi}(p'; E)$ are then given by

\[ \Sigma_{\sigma}(E) = \langle g G_{\pi\pi} g \rangle(E) - \tau(E) \langle \langle g G_{\pi\pi} h \rangle(E) \rangle^2, \] \[ \bar{\Gamma}_{\sigma \to \pi\pi}(p'; E) = g(p') + h(p') \tau(E) \langle h G_{\pi\pi} g \rangle(E), \] \[ \text{(A13)} \text{(A14)} \]

and $\bar{\Gamma}_{\pi\pi \to \sigma}(p; E) = \bar{\Gamma}_{\sigma \to \pi\pi}(p; E)$. The parameters in Eqs. \[ \text{(A5)}-\text{(A7)} \] are determined by fitting the phase shift of the $I = 0$ and s-wave $\pi\pi$ scattering up to $E = 1$ GeV, and the resulting values are $m_\sigma^0 = 700.0$ MeV, $g_0 = 1.638$, $h_0 = 0.556$, $c = 1.02$ fm, and $d = 0.514$ fm.
With the above $\pi\pi$ model, the $\sigma$ self-energy in the $\sigma N$ Green function, $\Sigma_{\sigma N}(k; W)$ in Eq. (6), is obtained by

$$
\Sigma_{\sigma N}(k; W) = \langle gG_{\pi\pi}g \rangle(k; W) - \tau(k; W)[\langle gG_{\pi\pi}h \rangle(k; W)]^2,
$$

(A15)

with

$$
\tau(k; W) = \frac{h_0}{1 - h_0 \langle hG_{\pi\pi}h \rangle(k; W)},
$$

(A16)

$$
\langle hG_{\pi\pi}h \rangle(k; W) = \frac{1}{W - E_N(k) - [M_{\pi\pi}(q) + k^2]^{1/2}} \times \frac{h(q)^2}{[M_{\pi\pi}(q) + k^2]^{1/2}} + \frac{1}{W - E_N(k) - [M_{\pi\pi}(q) + k^2]^{1/2} + i\varepsilon},
$$

(A17)

$$
\langle gG_{\pi\pi}g \rangle(k; W) = \frac{m_\sigma}{E_\sigma(k)} \int_{C_3} dq^2 \frac{M_{\pi\pi}(q)}{[M_{\pi\pi}(q) + k^2]^{1/2}} \times \frac{g(q)^2}{W - E_N(k) - [M_{\pi\pi}(q) + k^2]^{1/2} + i\varepsilon},
$$

(A18)

$$
\langle gG_{\pi\pi}h \rangle(k; W) = \frac{m_\sigma}{E_\sigma(k)} \int_{C_3} dq^2 \frac{M_{\pi\pi}(q)}{[M_{\pi\pi}(q) + k^2]^{1/2}} \times \frac{g(q)h(q)}{W - E_N(k) - [M_{\pi\pi}(q) + k^2]^{1/2} + i\varepsilon}.
$$

(A19)

The momentum integral path $C_3$ is appropriately deformed when we perform the analytic continuation of the scattering amplitudes. With the self-energies defined above, the branch points of the $\pi\Delta$, $\rho N$, and $\sigma N$ Green functions are those as listed in Table I. Although two branch points are found in the $\sigma N$ Green function, the second one at $(1032.3 - i247.7) + m_N$ MeV hardly affects the resonance properties shown in this work because of the large imaginary part.

**Appendix B: Model Lagrangian**

In this appendix, we present a set of Lagrangian for deriving the meson-exchange potentials $v_{M'B'MB}$ and $v_{M'B'\gamma N}$. The details of the $Z_{M'B'MB}^{(E)}(k'; k; W)$ term in Eq. (7) can be found in Ref. [1] and will not be shown here.

It is necessary to define notations associated with isospin quantum numbers. For the isospin $I = 1/2$ hadrons, we use the following field operators:

$$
N = \begin{pmatrix} p \\ n \end{pmatrix},
$$

(B1)

$$
\Xi = \begin{pmatrix} \Xi^- \\ \Xi^0 \end{pmatrix},
$$

(B2)

$$
K = \begin{pmatrix} K^+ \\ K^0 \end{pmatrix},
$$

(B3)

$$
K_e = \begin{pmatrix} K^0 \\ -K^- \end{pmatrix}.
$$

(B4)
For the isovector \((I = 1)\) pion field operator, we use the usual notations
\[
\vec{\pi} = (\pi^1, \pi^2, \pi^3),
\] (B5)
with the following isospin triplet
\[
\pi = \begin{pmatrix} \pi^+ \\ \pi^0 \\ \pi^- \end{pmatrix},
\] (B6)
where
\[
\pi^\pm = \mp \frac{1}{\sqrt{2}}(\pi^1 \pm i\pi^2),
\] (B7)
\[
\pi^0 = \pi^3.
\] (B8)
The same definition is also applied to other \(I = 1\) hadron operators. For \(\Delta\) with \(I = 3/2\), we define
\[
\Delta = \begin{pmatrix} \Delta^{++} \\ \Delta^+ \\ \Delta^0 \\ \Delta^- \end{pmatrix}.
\] (B9)

For the doublet states, the isospin operator \(\vec{\tau}\), with the spherical components \(\tau^\pm = \mp \sqrt{2}(\tau_1 \pm i\tau_2)\) and \(\tau_0 = \tau_3\), is defined by the following matrix elements
\[
\langle s m_s | \tau_m | s m'_s \rangle = \langle s m_s | s 1 m'_s m \rangle \langle s ||\tau||s \rangle / \sqrt{2s+1},
\] (B10)
where \(\langle J M | j_1 j_2 m_1 m_2 \rangle\) is the usual Clebsch-Gordon coefficient, \(m = \pm 1, 0\), and the reduced matrix element is \(\langle \frac{1}{2} ||\tau||\frac{1}{2} \rangle = \sqrt{6}\). The isospin operators \(\vec{T}_\Delta\) for the \(\Delta \to \Delta\) and \(\vec{T}\) for the \(N \to \Delta\) transitions are defined by
\[
\langle j_\Delta m_s | T_{\Delta,m} | j_\Delta m'_s \rangle = \langle j_\Delta m_s | j_\Delta 1 m'_s m \rangle \langle j_\Delta ||T_\Delta||j_\Delta \rangle / \sqrt{2j_\Delta + 1},
\] (B11)
\[
\langle j m_s | T_m | j' m'_s \rangle = \langle j m_s | j' 1 m'_s m \rangle \langle j ||T||j' \rangle / \sqrt{2j + 1},
\] (B12)
where \(m = \pm 1, 0\) is the spherical component of \(\vec{T}_\Delta\) and \(\vec{T}\), \(j_\Delta = 3/2, j, j' = 1/2 \text{ or } 3/2\), and the reduced matrix elements are
\[
\langle \frac{3}{2} ||T_\Delta|| \frac{3}{2} \rangle = \sqrt{15},
\] (B13)
\[
\langle \frac{3}{2} ||T|| \frac{3}{2} \rangle = -\langle \frac{1}{2} ||T|| \frac{3}{2} \rangle = 2.
\] (B14)

With the above definitions of isospin components, we list all Lagrangian used in our calculations. We follow the conventions of Bjoken and Drell \([67]\) in defining the metric tensor \(g_{\mu\nu}\) and the Dirac matrices \(\gamma_{\mu}\) and \(\gamma_5\). Also, we set \(\epsilon^{0123} = +1\).
1. Hadronic Interactions

a. $PBB'$ interaction

The interaction Lagrangian between a pseudoscalar-octet meson ($P$) and spin-1/2 octet baryons ($B, B'$) is given by

$$L_{PBB'} = \frac{f_{PBB'}}{m_P} \bar{B} \gamma_\mu \gamma_5 B' \partial^\mu P \times L_{PBB'}^{\text{iso}} + [\text{h.c. for } B \neq B']. \quad (B15)$$

Here $L_{PBB'}^{\text{iso}}$ is the isospin structure of the interactions given by

$$L_{\pi NN}^{\text{iso}} = (N^\dagger \bar{\tau} N) \cdot \bar{\pi}, \quad (B16)$$

$$L_{\pi \Xi \Xi}^{\text{iso}} = (\Xi^\dagger \bar{\tau} \Xi) \cdot \bar{\pi}, \quad (B17)$$

$$L_{\pi \Lambda \Sigma}^{\text{iso}} = \Lambda^\dagger (\Sigma \cdot \bar{\pi}), \quad (B18)$$

$$L_{\pi \Sigma \Sigma}^{\text{iso}} = i [\bar{\Sigma} \times \bar{\Sigma}] \cdot \bar{\pi}, \quad (B19)$$

$$L_{K \Sigma N}^{\text{iso}} = \bar{\Sigma}^\dagger \cdot (K^\dagger \bar{\tau} N), \quad (B20)$$

$$L_{K \Xi \Xi}^{\text{iso}} = (\Xi^\dagger \bar{\tau} K) \cdot \bar{\Sigma}, \quad (B21)$$

$$L_{K \Lambda N}^{\text{iso}} = \Lambda^\dagger (K^\dagger N), \quad (B22)$$

$$L_{K \Xi \Lambda}^{\text{iso}} = (\Xi^\dagger K) \Lambda, \quad (B23)$$

$$L_{\eta NN}^{\text{iso}} = (N^\dagger N) \eta, \quad (B24)$$

$$L_{\eta \Xi \Xi}^{\text{iso}} = (\Xi^\dagger \Xi) \eta, \quad (B25)$$

$$L_{\eta \Lambda \Lambda}^{\text{iso}} = \Lambda^\dagger \Lambda \eta, \quad (B26)$$

$$L_{\eta \Sigma \Sigma}^{\text{iso}} = (\bar{\Sigma}^\dagger \cdot \bar{\Sigma}) \eta. \quad (B27)$$

The coupling constants of $PBB'$ are fixed by the SU(3) relations and the $\pi NN$ coupling constant:

$$g_{\pi \Xi \Xi} = (1 - 2\alpha) g_{\pi NN}, \quad (B28)$$

$$g_{\pi \Lambda \Sigma} = \frac{2}{\sqrt{3}} \alpha g_{\pi NN}, \quad (B29)$$

$$g_{\pi \Sigma \Sigma} = 2(-1 + \alpha) g_{\pi NN}, \quad (B30)$$

$$g_{K \Sigma \Sigma} = (-1 + 2\alpha) g_{\pi NN}, \quad (B31)$$

$$g_{K \Xi \Xi} = (-1) g_{\pi NN}, \quad (B32)$$

$$g_{K \Lambda N} = \frac{1}{\sqrt{3}} (-3 + 2\alpha) g_{\pi NN}, \quad (B33)$$

$$g_{K \Xi \Lambda} = \frac{1}{\sqrt{3}} (+3 - 4\alpha) g_{\pi NN}, \quad (B34)$$

$$g_{\eta NN} = \frac{1}{\sqrt{3}} (+3 - 4\alpha) g_{\pi NN}, \quad (B35)$$

$$g_{\eta \Lambda \Lambda} = \frac{1}{\sqrt{3}} (-2\alpha) g_{\pi NN}, \quad (B36)$$

$$g_{\eta \Sigma \Sigma} = \frac{1}{\sqrt{3}} (+2\alpha) g_{\pi NN}, \quad (B37)$$
where \( g_{PBB'} = f_{PBB'}/m_P \), \( \alpha = 0.635 \), and \( f_{\pi NN} = \sqrt{4\pi \times 0.08} \). In this work, however, we will not follow the SU(3) relations (B31) and (B35) for the \( \eta NN \) and \( K\Sigma N \) couplings, but vary \( f_{\eta NN} \) and \( f_{K\Sigma N} \) freely in the fit.

b. \( VBB' \) interaction

The interaction Lagrangian between a vector-octet meson \((V)\) and spin-1/2 octet baryons \((B, B')\) is given by

\[
L_{VBB'} = +g_{VBB'}\overline{B}' \vec{\gamma} - \frac{\kappa_{VBB'}}{m_B + m_{B'}}\sigma_{\mu\nu}(\partial^\nu \vec{\gamma}^\mu) B' \times L_{VBB'}^{iso} + [\text{h.c. for } B \neq B'] . \tag{B38}
\]

The isospin structure of the interactions \( (L_{VBB'}^{iso}) \) involving \( \rho, K^*, K_c^*, \) and \( \omega_8 \) is given by the replacement of \( \pi \to \rho, K \to K^*, K_c \to K_c^*, \) and \( \eta \to \omega_8 \) in Eqs. (B16)-(B27). Here \( \omega_8 \) is the 8th component of the octet representation of the vector mesons. Assuming the ideal mixing, it is related to the physical \( \omega \) and \( \phi \) mesons as

\[
\omega_8 = \frac{1}{\sqrt{3}} \omega - \sqrt{\frac{2}{3}} \phi . \tag{B39}
\]

In this work, only \( g_\rho NN, \kappa_\rho NN, g_\omega NN \), and \( \kappa_\omega NN \) are free parameters for \( VBB' \) coupling constants determined by the global fit. As for the other \( VBB' \) interactions, \( g_{VBB'} \) is fixed by the value of \( g_\rho NN \) and the corresponding SU(3) relations to Eqs. (B28)-(B37) with the replacement of \( \pi \to \rho, K \to K^*, K_c \to K_c^*, \) and \( \eta \to \omega_8 \), while \( \kappa_{VBB'} \) is fixed with \( \kappa_{VBB'}/(m_B + m_{B'}) \equiv \kappa_{\rho NN}/(2m_N) \).

c. \( SBB' \) interaction

The interaction Lagrangian between a scalar meson \((S)\) and spin-1/2 octet baryons \((B, B')\) used in this work is:

\[
L_{SBB'} = +g_{SBB'}\overline{B}'S \times L_{SBB'}^{iso} + [\text{h.c. for } B \neq B'] . \tag{B40}
\]

The isospin structure of the interactions \( (L_{SBB'}^{iso}) \) is given by

\[
\begin{align*}
L_{\sigma NN} &= (N^\dagger N)\sigma , \tag{B41} \\
L_{f_0 NN} &= (N^\dagger N)f_0 , \tag{B42} \\
L_{\kappa\Lambda N} &= \Lambda^\dagger (\kappa^\dagger N) , \tag{B43} \\
L_{\kappa\Sigma N} &= \Sigma^\dagger (\kappa^\dagger \bar{T} N) . \tag{B44}
\end{align*}
\]

Other \( SBB' \) interactions are not considered in this work.

d. \( ABB' \) interaction

As for the interaction between a axial-vector meson \((A)\) and spin-1/2 octet baryons \((B, B')\), we consider only \( a_1 NN \) interaction given by

\[
L_{a_1 NN} = g_{a_1 NN}\overline{N} \gamma^\mu \gamma_5 \overline{T} N \cdot \vec{a}_{1\mu} . \tag{B45}
\]
e. $PVBB'$ and $VVBB'$ interaction

The following contact terms are also included in the calculation,

\[
L_{\rho\pi NN} = \frac{f_{\pi NN}}{m_\pi} g_{\rho NN} \bar{\psi}_N \gamma_\mu \gamma_5 \bar{\tau} \psi_N \cdot [\bar{\rho}_\mu \times \bar{\tau}], \quad (B46)
\]
\[
L_{\rho\rho NN} = -\frac{\kappa_\rho g_{\rho NN}^2}{8m_N} \bar{\psi}_N \sigma^{\mu\nu} \bar{\tau} \psi_N \cdot [\bar{\rho}_\mu \times \bar{\rho}_\nu]. \quad (B47)
\]

Note that these contact terms are derived from applying $[\partial^\mu \to \partial^\mu - g_{\rho NN} \bar{\rho}^\mu \times]$ to $L_{\pi NN}$ and $L_{\rho NN}$, respectively. However, in this work we replace $f_{\pi NN} g_{\rho NN}$ [Eq. (B46)] with a new parameter $c_{\rho\pi NN}$ [Eq. (B47)] and vary the new parameter in the fit.

f. $PBD$ interaction

The interaction Lagrangian involving a pseudoscalar-octet meson ($P$), a spin-1/2 octet baryon ($B$), and a spin-3/2 decuplet baryon ($D$) is given by

\[
L_{PBD} = -\frac{f_{PBD}}{m_P} \bar{B} D^\mu \partial_\mu P \times L_{PBD}^{iso} + [\text{h.c. for } B \neq B'], \quad (B48)
\]

The isospin structure of the interactions ($L_{PBD}^{iso}$) is given by

\[
L_{\pi N\Delta}^{iso} = (N^\dagger \vec{T}\Delta) \cdot \vec{\pi}, \quad (B49)
\]
\[
L_{\pi \Lambda\Sigma}^{iso} = \Lambda^\dagger (\vec{\Sigma}^* \cdot \vec{\pi}), \quad (B50)
\]
\[
L_{\pi \Sigma\Sigma}^{iso} = i[\vec{\Sigma}^\dagger \times \vec{\Sigma}] \cdot \vec{\pi}, \quad (B51)
\]
\[
L_{K\Lambda\Sigma}^{iso} = (N^\dagger \pi K) \cdot \vec{\Sigma}^*. \quad (B52)
\]

g. $VBD$ interaction

As for the interaction involving a vector-octet meson ($V$), a spin-1/2 octet baryon ($B$), and a spin-3/2 decuplet baryon ($D$), we consider only $\rho NN$ interaction:

\[
L_{\rho N\Delta} = -i\frac{f_{\rho N\Delta}}{m_\rho} \bar{\Delta}^{\mu} \gamma^\nu \gamma^5 [\partial_\mu \bar{\rho}_\nu - \partial_\nu \bar{\rho}_\mu] \cdot \vec{T} N + \text{h.c.} \quad (B53)
\]

h. $PDD'$ interaction

As for the interaction between a pseudoscalar-octet meson ($P$), spin-3/2 decuplet baryons ($D, D'$), we consider only $\pi\Delta\Delta$ interaction:

\[
L_{\pi\Delta\Delta} = +\frac{f_{\pi\Delta\Delta}}{m_\pi} \bar{\Delta}_\mu \gamma^\nu \gamma^5 \vec{T} \Delta^\mu \cdot \partial_\nu \vec{\pi}, \quad (B54)
\]
i. \( VDD' \) interaction

As for the interaction between a vector-octet meson \((V)\), spin-3/2 decuplet baryons \((D, D')\), we consider only the \( \rho \Delta \Delta \) interaction:

\[
L_{\rho \Delta \Delta} = +g_{\rho \Delta \Delta} \bar{\Delta}_\alpha \left[ \vec{\rho} - \frac{k_{\rho \Delta \Delta}}{2m_\Delta} \sigma_{\mu\nu}(\partial^\nu \bar{\rho}^\mu) \right] \cdot \vec{T}_\Delta \Delta^\alpha .
\]  

(B55)

j. \( VPP' \) interaction

The interaction Lagrangian between a vector-octet meson \((V)\) and pseudoscalar-octet mesons \((P, P')\) used in this work is given by

\[
L_{\rho \pi \pi} = +g_{\rho \pi \pi} \left[ \vec{\pi} \times \partial_\mu \vec{\pi} \right] \cdot \vec{\rho}^\mu , \quad \text{(B56)}
\]

\[
L_{\rho KK} = +ig_{\rho KK}(K^\dagger \tau_3 \partial_\mu K) \cdot \vec{\rho}^\mu + \text{h.c.} , \quad \text{(B57)}
\]

\[
L_{\kappa K^* \pi} = +ig_{\kappa K^* \pi} \left[ (K^\dagger \tau_3 \partial_\mu K) \cdot \vec{\pi} - K^* \tau_3 \partial_\mu \pi K \right] \bar{\rho}_{\eta} + \text{h.c.} , \quad \text{(B58)}
\]

\[
L_{\omega KK} = +ig_{\omega KK} \left[ (K^\dagger \tau_3 \partial_\mu K) - (\partial_\mu K^\dagger) \right] \omega_{\eta} , \quad \text{(B59)}
\]

\[
L_{\kappa^* \kappa \eta} = +ig_{\kappa^* \kappa \eta} K^* \tau_3 \partial_\mu \eta K + \text{h.c.} . \quad \text{(B60)}
\]

In this work, the coupling constant \( g_{VPP'} \) is fixed by the SU(3) relation,

\[
g_{\rho KK} = \frac{1}{2} g_{\rho \pi \pi} , \quad \text{(B61)}
\]

\[
g_{K^* \pi \pi} = \frac{1}{2} g_{\rho \pi \pi} , \quad \text{(B62)}
\]

\[
g_{\omega KK} = \frac{1}{\sqrt{3}} g_{\omega KK} = \frac{1}{2} g_{\rho \pi \pi} , \quad \text{(B63)}
\]

\[
g_{\phi KK} = -\sqrt{\frac{2}{3}} g_{\omega KK} = -\sqrt{\frac{2}{3}} g_{\rho \pi \pi} , \quad \text{(B64)}
\]

\[
g_{K^* \kappa \eta} = \sqrt{\frac{3}{2}} g_{\rho \pi \pi} , \quad \text{(B65)}
\]

so that only \( g_{\rho \pi \pi} \) is a free parameter for the \( VPP' \) couplings.

k. \( SPP' \) interaction

The interaction Lagrangian between a scalar meson \((S)\) and pseudoscalar-octet mesons \((P, P')\) used in this work is given by

\[
L_{\sigma \pi \pi} = -\frac{g_{\sigma \pi \pi}}{2m_\pi} (\partial_\mu \vec{\pi}) \cdot (\partial_\nu \vec{\pi}) + \frac{g_{\sigma \pi \pi} m_\pi^2}{2f_\pi} \cdot \vec{\pi} \sigma , \quad \text{(B66)}
\]

\[
L_{f_0 \pi \pi} = -\frac{g_{f_0 \pi \pi}}{2m_\pi} (\partial_\mu \vec{\pi}) \cdot (\partial_\nu \vec{\pi}) f_0 . \quad \text{(B67)}
\]

\[
L_{\kappa K \pi} = -\frac{g_{\kappa K \pi}}{m_\pi} (\partial_\mu K^\dagger) \vec{\pi}_\kappa \cdot (\partial_\nu \vec{\pi}) + \text{h.c.} , \quad \text{(B68)}
\]

\[
L_{\kappa \kappa \eta} = -\frac{g_{\kappa \kappa \eta}}{m_\eta} (\partial_\mu K^\dagger) \kappa (\partial_\nu \eta) + \text{h.c.} . \quad \text{(B69)}
\]
1. $VV'P$ interaction

As for the interaction between a pseudoscalar-octet meson ($P$) and vector-octet mesons ($V, V'$), in this work we consider only $\omega \rho \pi$ interaction:

$$L_{\omega \rho \pi} = -\frac{g_{\omega \rho \pi}}{m_{\omega}} \epsilon_{\mu \alpha \lambda \nu} (\partial^\alpha \vec{P}) \cdot (\partial^\lambda \vec{\pi}) \omega^\nu.$$  \hspace{1cm} (B70)

2. Electromagnetic Interactions

The electromagnetic interactions are obtained from the usual non-interacting Lagrangian and the above hadronic Lagrangian by using the minimum substitution $\partial_\mu \rightarrow \partial_\mu - ieA_\mu$. The resulting Lagrangian divided by $-e$ are listed below.

a. $\gamma BB'$ interaction

The interaction Lagrangian between a photon and spin-1/2 octet baryons is given by

$$L_{\gamma BB'} = \hat{B} \left[ \hat{\epsilon}_{BB'}(Q^2) A - \hat{\kappa}_{BB'}(Q^2) \sigma^{\mu \nu} (\partial_\nu A_\mu) \right] B' + [h.c. \text{ for } B \neq B'].$$  \hspace{1cm} (B71)

Here we have defined

$$\hat{\epsilon}_{NN} = \frac{F_{1S} + F_{1V} \tau^3}{2},$$  \hspace{1cm} (B72)

$$\hat{\kappa}_{NN} = \frac{F_{2S} + F_{2V} \tau^3}{2},$$  \hspace{1cm} (B73)

$$\hat{\epsilon}_{\Lambda \Lambda} = 0,$$  \hspace{1cm} (B74)

$$\hat{\kappa}_{\Lambda \Lambda} = -0.61,$$  \hspace{1cm} (B75)

$$\hat{\epsilon}_{\Sigma \Sigma} = T_3^\Sigma,$$  \hspace{1cm} (B76)

$$\hat{\kappa}_{\Sigma \Sigma} = \kappa^\Sigma_S + \kappa^\Sigma_V T_3^\Sigma,$$  \hspace{1cm} (B77)

$$\hat{\epsilon}_{\Lambda \Sigma} \sim (0, 0, 0),$$  \hspace{1cm} (B78)

$$\hat{\kappa}_{\Lambda \Sigma} = (0, -1.61, 0).$$  \hspace{1cm} (B79)

Here $F_{1S} = F_{1V} = 1$; $F_{2S} = \mu_p + \mu_n - 1 \sim -0.12$; $F_{2V} = \mu_p - \mu_n - 1 \sim 3.7$; $\kappa^\Sigma_S = 0.65$; $\kappa^\Sigma_V = 0.81$; and $T_3^\Sigma = \text{diag}(1, 0, -1)$.

b. $\gamma PBB'$ and $\gamma VBB'$ interaction

The following 4-point interactions are obtained by applying the minimum substitution $\partial_\mu \rightarrow \partial_\mu - ieA_\mu$ to the $PBB'$ and $VBB'$ interactions defined in Appendices B1a and B1b.
Here the symbol \([\vec{A} \times \vec{B}]_3\) in the above equations means the 3rd component of the outer product of the isospin vectors \(\vec{A}\) and \(\vec{B}\). In this work, we multiply the \(\gamma\pi NN\), \(\gamma KNA\), and \(\gamma KNS\) interactions by additional phenomenological factors \(c_{\gamma\pi NN}\), \(c_{\gamma KNA}\), and \(c_{\gamma KNS}\), respectively, and we treat those factors as parameters in the fit.

c. \(\gamma BD\) interaction

The following Lagrangian is used for the interactions involving a photon (\(\gamma\)), spin-1/2 octet baryon (\(B\)), and a spin-3/2 decuplet baryon (\(D\)),

\[
L_{\gamma N\Delta} = -i\bar{\Delta} \Gamma_{\mu}^{\gamma N\Delta} T^3 N A^\mu + \text{h.c.},
\]

\[
L_{\gamma \Sigma \Sigma'} = -i(\Sigma')^{\mu} \Gamma_{\mu}^{\gamma \Sigma \Sigma'} \Sigma A^\mu + \text{h.c.}.
\]

The matrix element of \(\gamma BD\) vertex is explicitly given by

\[
\langle D(p_D)|\Gamma_{\mu}^{\gamma N\Delta}|B(p_B)\rangle = \frac{m_D + m_B}{2m_B} \frac{1}{(m_D + m_B)^2 - q^2} \times \left[ \left( G_{M}^{DB} - G_{E}^{DB} \right) 3\epsilon_{\mu\alpha\beta\gamma} P^\alpha q^\beta + G_{E}^{DB} i\gamma_5 \frac{12}{(m_D - m_B)^2 - q^2} \epsilon_{\mu\lambda\alpha\beta} P^\alpha q^\beta q_{\gamma\delta} P^\nu q_{\nu\mu} (q^2 P_\nu - q \cdot P q_\nu) \right].
\]

with \(P = (p_D + p_B)/2\) and \(q = p_D - p_B\). Note that the index \(\mu\) of \(\Gamma_{\mu}^{\gamma N\Delta}\) contracts with the \(D\) field and \(\nu\) with the photon field. The \(\gamma N\Delta\) coupling strength \(G_{M}^{\gamma N\Delta} = 1.85, G_{E}^{\gamma N\Delta} = 0.025, \) and \(G_{C}^{\gamma N\Delta} = -0.238\) are taken from the SL model \[15\]. On the other hand, for the \(\gamma \Sigma \Sigma'\) interactions, in this work we set \(G_{E}^{\Sigma' \Sigma} = G_{E}^{\Sigma' \Sigma} = 0\), and only \(G_{E}^{\gamma (\Sigma') \Sigma^0}\), and \(G_{M}^{\gamma (\Sigma') \Sigma^\pm}\) are treated as free parameters varied freely in the fit.

d. \(\gamma PBD\) interaction

The following 4-point interaction is given by applying the minimum substitution \(\partial_\mu \rightarrow \partial_\mu - i e A_\mu\) to \(L_{\pi N\Delta}\).

\[
L_{\gamma \pi NN} = +\frac{f_{\pi NN}}{m_\pi} \left[ (\bar{\Delta} \mu T N) \times \vec{\pi} \right]_3 A_\mu + \text{h.c.}.
\]
e. \( \gamma DD' \) interaction

As for the interaction involving a photon (\( \gamma \)) and spin-3/2 decuplet baryons (\( D, D' \)), we consider only the \( \gamma \Delta \Delta \) interaction,

\[
L_{\gamma \Delta \Delta} = + \sqrt{2} \left( T_3^\Delta + \frac{1}{2} \right) \left[ -\gamma^\mu g_{\rho\nu} + (g_\eta \gamma^\nu + g_\rho^\eta \gamma^\rho) + \frac{1}{3} \gamma_\eta \gamma^\mu \gamma_\nu \right] \Delta^\nu A_\mu . 
\]

(f) \( \gamma PP' \) interaction

As for the interaction involving a photon (\( \gamma \)) and pseudoscalar octet mesons (\( P, P' \)), in this work only the following \( \gamma \pi \pi \) and \( \gamma KK \) interactions are considered:

\[
L_{\gamma \pi \pi} = + \left[ \vec{\pi} \times (\partial^\mu \vec{\pi}) \right] \cdot \vec{A}_\mu , \tag{B89}
\]

\[
L_{\gamma KK} = + i \left[ K^- \partial^\mu K^+ - (\partial^\mu K^-) K^+ \right] A_\mu . \tag{B90}
\]

(g) \( \gamma V P \) interaction

The following Lagrangian is considered for interactions involving a photon (\( \gamma \)), a vector octet mesons (\( V \)), and a pseudoscalar octet mesons (\( P \)),

\[
L_{\gamma \rho \pi \pi} = + \frac{g_{\gamma \rho \pi}}{m_\pi} \epsilon_{\alpha \beta \gamma \delta} (\partial^\alpha A^\beta)(\partial^\gamma \rho^\delta) \cdot \vec{\pi} , \tag{B91}
\]

\[
L_{\gamma \omega \pi \pi} = + \frac{g_{\gamma \omega \pi}}{m_\pi} \epsilon_{\alpha \beta \gamma \delta} (\partial^\alpha A^\beta)(\partial^\gamma \omega^\delta) \pi^\pi , \tag{B92}
\]

\[
L_{\gamma \rho \rho} = + \frac{g_{\gamma \rho \rho}}{m_\rho} \epsilon_{\mu \nu \rho \delta} (\partial_\mu A_\nu)(\partial_\rho A_\delta), \tag{B93}
\]

\[
L_{\gamma \omega \omega} = + \frac{g_{\gamma \omega \omega}}{m_\omega} \epsilon_{\alpha \beta \gamma \delta} (\partial^\alpha A^\beta)(\partial^\gamma \omega^\delta) \eta , \tag{B94}
\]

\[
L_{\gamma K^* K} = + \frac{g_{\gamma K^* K}}{m_K} \epsilon_{\alpha \beta \gamma \delta} \left[ \bar{K}^0 (\partial^\gamma K^{*0}) + K^0 (\partial^\gamma \bar{K}^{*0}) \right] \partial^\alpha A^\beta + \frac{g_{\gamma K^* K}}{m_K} \epsilon_{\alpha \beta \gamma \delta} \left[ K^+ (\partial^\gamma K^{*-}) + K^- (\partial^\gamma \bar{K}^{*-}) \right] \partial^\alpha A^\beta . \tag{B95}
\]

In this work, we treat \( g_{\gamma \rho \pi}, g_{\gamma \omega \pi}, g_{\gamma \rho \rho}, \) and \( g_{\gamma \omega \omega} \) as free parameters in the fit, while we use the fixed values for \( \gamma K^* K \) couplings, i.e., \( g_{\gamma K^* K}^0 / m_K = -0.388 \text{ GeV}^{-1} \) and \( g_{\gamma K^* K}^c = 0.254 \text{ GeV}^{-1} \). [63]

(h) \( \gamma VPP' \) interaction

The following 4-point interaction is given by applying the minimum substitution \( \partial_\mu \rightarrow \partial_\mu - ieA_\mu \) to \( L_{\rho \pi \pi} \).

\[
L_{\gamma \rho \pi \pi} = - g_{\rho \pi \pi} \left[ (\rho^\mu \times \vec{\pi}) \times \vec{\pi} \right]_3 A_\mu . \tag{B97}
\]
i. $\gamma AP$ interaction

As for the interaction involving a photon ($\gamma$), an axialvector meson ($A$), and a pseudoscalar meson ($P$), in this paper only the $\gamma a_1 \pi$ interaction is considered:

$$L_{\gamma a_1 \pi} = \frac{1}{m_{a_1}} (\partial^\mu A^\nu - \partial^\nu A^\mu) \times \{ 2[(\partial_{\mu} \vec{p}) \times \vec{a}_{1\nu}]_3 - 2[(\partial_{\nu} \vec{p}) \times \vec{a}_{1\mu}]_3 + [\vec{p} \times (\partial_{\mu} \vec{a}_{1\nu} - \partial_{\nu} \vec{a}_{1\mu})]_3 \}. \quad (B98)$$

j. $\gammaVV'$ interaction

As for the interaction involving a photon ($\gamma$), and vector octet mesons ($V, V'$), in this paper only the $\gamma \rho \rho$ interaction is considered:

$$L_{\gamma \rho \rho} = + [(\partial^\mu \vec{p'} - \partial^\nu \vec{\rho'}) \times \vec{\rho'}_3] A_\mu . \quad (B99)$$

Appendix C: Matrix elements of meson-baryon potentials

It is convenient to get the partial-wave matrix elements of the meson-exchange potential $v_{MB,M'B'}$ by first evaluating $v_{MB,M'B'}$ in helicity representation and then transforming them into the usual $(LS)JT$ representation with $J$, $T$, $L$, and $S$ denoting the total angular momentum, isospin, orbital angular momentum, and spin quantum numbers, respectively. For each meson-baryon $(MB)$ state, we use $k(p)$ to denote the momentum of $M(B)$. In the center of mass frame, we thus have $\vec{p} = -\vec{k}$. Following the Jacob-Wick formulation, the partial-wave matrix elements of $v_{MB,M'B'}$ can be written as

$$v_{LS'M'B',LSMB}^{JT}(k',k,W) = \sum_{\chi_M^\prime \lambda_M^\prime \lambda_M \lambda_B} \frac{\sqrt{(2L + 1)(2L' + 1)}}{2J + 1} \chi_M^\prime \lambda_M^\prime \lambda_M \lambda_B \times \langle j_M^J L_M^J B_M^J \lambda_M^J - \lambda_B^J | S' S'_{z} | (L'S0S_0' | J S_z') \rangle \times \langle j_B^J L_B^J B_B^J \lambda_B^J - \lambda_B^J | S S_z | (LS0S | J S_z) \rangle \times \langle J, k' \chi_M^J - \lambda_B^J | v_{M'B',MB} | J, k \lambda_M - \lambda_B \rangle , \quad (C1)$$

where $j_M$ and $j_B$ are the spins of the meson and baryon, respectively, and $\lambda_M$ and $\lambda_B$ are their helicities, and

$$\langle J, k' \chi_M^J - \lambda_B^J | v_{M'B',MB} | J, k \lambda_M - \lambda_B \rangle$$

$$= 2\pi \int_{-1}^{+1} d(cos \theta) d_{\lambda_M - \lambda_B, \chi_M - \lambda_B}^J (\theta) \times \langle M'(-\vec{k'}, s'_M \chi_M^J) B'(-\vec{k}, s_B' \lambda_B^J) | v_{M'B',MB} | M(\vec{k}, s_M \lambda_M) B(-\vec{k}, s_B, -\lambda_B) \rangle . \quad (C2)$$

Here we have chosen the coordinates such that

$$\vec{k'} = (k' \sin \theta, 0, k' \cos \theta), \quad (C3)$$

$$\vec{k} = (0, 0, k), \quad (C4)$$

58
and the helicity eigenstates are defined by

\[ \hat{k} \cdot \vec{s}_M | M(\vec{k}, s_M \lambda_M) \rangle = \lambda_M | M(\vec{k}, s_M \lambda_M) \rangle , \quad (C5) \]

\[ [-\hat{k} \cdot \vec{s}_B] | B(\vec{k}, s_B \lambda_B) \rangle = \lambda_B | B(\vec{k}, s_B \lambda_B) \rangle . \quad (C6) \]

Note the “−” sign in Eq. (C6).

To evaluate the matrix elements in the right hand side of Eq. (C2), we define (suppressing the helicity and isospin indices)

\[
\langle k'(j), p'| v_{M'B',MB}| k(i), p \rangle = \frac{1}{(2\pi)^3} \sqrt{\frac{m'_B}{E_{B'}(p')}} \frac{1}{\sqrt{2E_{M'}(k')}} \frac{1}{\sqrt{2E_M(k)}} \bar{u}_{B'}(\vec{p}') \bar{V}(n) u_B(\vec{p}) . \quad (C7)
\]

Here the label \( n \) indicates the considered \( MB \to M'B' \) transition as specified in Table X; \( i, j \) are the isospin indices of the mesons. We also use the notation \( q = k' - k \) or \( q = p - p' \) below. The expressions of each term in \( \bar{V}(n) \) are given in the following subsections.

1. \( \pi(k, i) + N(p) \to \pi(k', j) + N(p') \)

\[
\bar{V}(1) = \bar{V}_a^1 + \bar{V}_b^1 + \bar{V}_c^1 + \bar{V}_d^1 + \bar{V}_e^1 + \bar{V}_f^1 , \quad (C8)
\]
with

\[
\begin{align*}
\tilde{V}_a^1 &= \left( \frac{f_{\pi NN}}{m_\pi} \right)^2 \frac{k_i \gamma^5 \tau^j S_N(p+k) \, k_j \gamma^5 \tau^i}{m_\pi^2} , \\
\tilde{V}_b^1 &= \left( \frac{f_{\pi NN}}{m_\pi} \right)^2 \frac{k_i \gamma^5 \tau^j S_N(p-k') \, k_j \gamma^5 \tau^i}{m_\pi^2} , \\
\tilde{V}_c^1 &= \left( \frac{f_{\pi N\Delta}}{m_\pi} \right)^2 \frac{k_i \alpha(T^\dagger) \gamma^5 \tau^j S_\Delta(p-k') \, k_j \gamma^5 \tau^i}{m_\pi^2} , \\
\tilde{V}_d^1 &= -C_{V1} \left[ (k+ k') + C_{V2} \frac{\kappa_\rho}{4m_N} \{ (k+ k') \, g - g(k+ k') \} \right] i \epsilon_{jiil} \frac{\tau^l}{2} + g_{\rho NN} \rho_{\pi\pi} \frac{q^2}{m_\rho^2(q^2 - m_\rho^2)} \left[ (k+ k') + \frac{\kappa_\rho}{4m_N} \{ (k+ k') \, g - g(k+ k') \} \right] i \epsilon_{jiil} \frac{\tau^l}{2} , \\
\tilde{V}_e^1 &= +C_S \frac{k \cdot k'}{m_\pi} \delta_{ij} \\
&- \left( g_{\sigma NN} g_{\sigma \pi\pi} \frac{q^2}{m_\sigma^2(q^2 - m_\sigma^2)} + g_{f_0 NN} g_{f_0 \pi\pi} \frac{q^2}{m_{f_0}^2(q^2 - m_{f_0}^2)} \right) \frac{k \cdot k'}{m_\pi} \delta_{ij} , \\
\tilde{V}_f^1 &= -\tilde{\epsilon}_{\sigma NN} \frac{g_{\sigma \pi\pi} m_\pi^2}{f_\pi} \frac{1}{q^2 - m_\sigma^2} \delta_{ij} .
\end{align*}
\]

Here one can see that parameters $C_{V1}$, $C_{V2}$, and $C_S$, which are somewhat unusual and will require some explanation, appear in the meson-exchange potentials $\tilde{V}_a^1$ and $\tilde{V}_e^1$. Let us explain this by taking $\rho$-meson exchange potential $\tilde{V}_d^1$ as an example. It is first noticed that if one takes $C_{V1} = g_{\rho NN} \rho_{\pi\pi}/m_\rho^2$ and also $C_{V2} = 1$, $\tilde{V}_d^1$ reduces to the familiar $\rho$-meson exchange $\pi N \to \pi N$ potential derived from $L_{\rho \pi \pi}$ and $L_{\rho NN}$. In effective theories, the propagator of heavy mesons $M$ is expanded as

\[
\frac{1}{q^2 - m_M^2} = -\frac{1}{m_M^2} + \mathcal{O}\left( \frac{q^2}{m_M^4} \right) ,
\]

and effect of the heavy-particle exchanges is absorbed into contact terms of the effective theories. We have taken into account contributions of higher excited $\rho$ meson states phenomenologically by making $C_{V1}$ and $C_{V2}$ as free parameters that can be different from $C_{V1} = g_{\rho NN} \rho_{\pi\pi}/m_\rho^2$ and $C_{V2} = 1$, respectively. Furthermore, we attach different cutoff factors for the first and second terms of $\tilde{V}_d^1$. A similar prescription has been applied also to the scalar-meson exchange potential $\tilde{V}_e^1$. In addition, in this work we include a phenomenological contact potential $\tilde{V}_1^1 = c_{S31}$ in getting a good fit to $S_{31}$ partial wave. We do not need this for other partial waves.

2. $\pi(k, \delta) + N(p) \to \eta(k') + N(p')$

\[
\bar{V}(2) = \bar{V}_a^2 + \bar{V}_b^2 ,
\]

\[60\]
with
\[ \bar{V}_a^2 = \frac{f_{\pi NN} f_{\eta NN}}{m_\pi m_\eta} \kappa' \gamma_5 S_N(p + k) \slashed{k} \gamma_5 \tau^i, \]  
\[ \bar{V}_b^2 = \frac{f_{\pi NN} f_{\eta NN}}{m_\pi m_\eta} \kappa' \gamma_5 \tau^i S_N(p - k') \slashed{k'} \gamma_5. \]  

3. \( \eta(k) + N(p) \rightarrow \eta(k') + N(p') \)

\[ \bar{V}(3) = \bar{V}_a^3 + \bar{V}_b^3, \]  

with
\[ \bar{V}_a^3 = \left( \frac{f_{\eta NN}}{m_\eta} \right)^2 \kappa' \gamma_5 S_N(p + k) \slashed{k} \gamma_5, \]  
\[ \bar{V}_b^3 = \left( \frac{f_{\eta NN}}{m_\eta} \right)^2 \kappa' \gamma_5 S_N(p - k') \slashed{k'} \gamma_5. \]

4. \( \pi(k, i) + N(p) \rightarrow \sigma(k') + N(p') \)

\[ \bar{V}(4) = \bar{V}_a^4 + \bar{V}_b^4 + \bar{V}_c^4, \]  

with
\[ \bar{V}_a^4 = ig_{\sigma NN} \frac{f_{\pi NN}}{m_\pi} S_N(p + k) \slashed{k} \gamma_5 \tau^i, \]  
\[ \bar{V}_b^4 = ig_{\sigma NN} \frac{f_{\pi NN}}{m_\pi} \kappa' \gamma_5 S_N(p - k') \tau^i, \]  
\[ \bar{V}_c^4 = i \frac{f_{\pi NN} g_{\sigma \pi}}{m_\pi^2} \gamma_5 \tau^i \frac{q \cdot k}{q^2 - m_\pi^2}. \]

5. \( \eta(k) + N(p) \rightarrow \sigma(k') + N(p') \)

\[ \bar{V}(5) = \bar{V}_a^5 + \bar{V}_b^5, \]  

with
\[ \bar{V}_a^5 = ig_{\sigma NN} \frac{f_{\eta NN}}{m_\eta} S_N(p + k) \slashed{k} \gamma_5, \]  
\[ \bar{V}_b^5 = ig_{\sigma NN} \frac{f_{\eta NN}}{m_\eta} \kappa' \gamma_5 S_N(p - k'). \]
6. \( \sigma(k) + N(p) \rightarrow \sigma(k') + N(p') \)

\[
\bar{V}(6) = \bar{V}_a^6 + \bar{V}_b^6 ,
\]

with

\[
\begin{align*}
\bar{V}_a^6 &= g_{\sigma NN}^2 S_N(p + k) , \\
\bar{V}_b^6 &= g_{\sigma NN}^2 S_N(p - k') .
\end{align*}
\]

7. \( \pi(k, i) + N(p) \rightarrow \rho'(k', j) + N(p') \)

\[
\bar{V}(7) = \bar{V}_a^7 + \bar{V}_b^7 + \bar{V}_c^7 + \bar{V}_d^7 + \bar{V}_e^7 ,
\]

with

\[
\begin{align*}
\bar{V}_a^7 &= i \frac{f_{\pi NN}}{m_\pi} g_{\rho NN} \Gamma' \rho' S_N(p + k) \ k_5 \tau^i , \\
\bar{V}_b^7 &= i \frac{f_{\pi NN}}{m_\pi} g_{\rho NN} \ k_5 \tau^i S_N(p - k') \Gamma' \rho' , \\
\bar{V}_c^7 &= \frac{f_{\pi NN}}{m_\pi} g_{\rho NN} \epsilon_{ijkl} \tau^l \ (q - k) \cdot \epsilon_{\rho'}^* \ q_5 \\
\bar{V}_d^7 &= - \frac{f_{\pi NN}}{m_\pi} g_{\rho NN} \epsilon_{\rho'}^* \ q_5 \epsilon_{ijkl} \tau^l , \\
\bar{V}_e^7 &= g_{\omega NN} g_{\omega NN} \delta_{ij} \ \frac{\epsilon_{\alpha \beta \gamma} \epsilon_{\rho'}^* \ k_{\alpha} k_{\beta}}{q^2 - m_\omega^2} \left[ \gamma^\delta + \frac{\kappa_\omega}{4m_N} (\gamma^\delta \ q - \ q_5 \gamma^\delta) \right],
\end{align*}
\]

where

\[
\Gamma' \rho' = \frac{\tau^j}{2} \left[ \epsilon_{\rho'}^* + \frac{\kappa_{\rho'}}{4m_N} (\epsilon_{\rho'}^* \ k' - \ k' \epsilon_{\rho'}^*) \right].
\]

8. \( \eta(k) + N(p) \rightarrow \rho(k', j) + N(p') \)

\[
\bar{V}(8) = \bar{V}_a^8 + \bar{V}_b^8 ,
\]

with

\[
\begin{align*}
\bar{V}_a^8 &= i \frac{f_{\eta NN}}{m_\eta} g_{\rho NN} \Gamma' \rho' S_N(p + k) \ k_5 , \\
\bar{V}_b^8 &= i \frac{f_{\eta NN}}{m_\eta} g_{\rho NN} \ k_5 S_N(p - k') \Gamma' \rho' .
\end{align*}
\]
9. \( \sigma(k) + N(p) \rightarrow \rho(k', j) + N(p') \)

\[
\bar{V}(9) = \bar{V}_a^9 + \bar{V}_b^9 ,
\]

with

\[
\bar{V}_a^9 = g_{\rho NN} g_{\sigma NN} \Gamma_\rho S_N(p + k) ,
\]
\[
\bar{V}_b^9 = g_{\rho NN} g_{\sigma NN} S_N(p - k') \Gamma_\rho' .
\] (C44)

10. \( \rho(k, i) + N(p) \rightarrow \rho'(k', j) + N(p') \)

\[
\bar{V}(10) = \bar{V}_a^{10} + \bar{V}_b^{10} + \bar{V}_c^{10} ,
\]

with

\[
\bar{V}_a^{10} + \bar{V}_b^{10} = g_{\rho NN}^2 [\Gamma_\rho S_N(p + k) \Gamma_\rho + \Gamma_\rho S_N(p - k') \Gamma_\rho'] ,
\] (C45)

where

\[
\Gamma_\rho = \frac{\tau^i}{2} \left[ \varphi_\rho - \frac{\kappa_\rho}{4m_N} (\varphi_\rho \cdot k) \gamma_5 \varphi_\rho \right] ,
\] (C46)

and

\[
\bar{V}_c^{10} = i \frac{\kappa_\rho g_{\rho NN}^2}{8m_N} [\varphi_\rho \varphi_\rho^* - \varphi_\rho^* \varphi_\rho] \epsilon_{ij} \tau^j .
\] (C47)

11. \( \pi(k, i) + N(p) \rightarrow \pi'(k', j) + \Delta(p') \)

\[
\bar{V}(11) = \bar{V}_a^{11} + \bar{V}_b^{11} + \bar{V}_c^{11} + \bar{V}_d^{11} + \bar{V}_e^{11} ,
\]

with

\[
\bar{V}_a^{11} = \frac{f_{\pi NN} f_{\pi N\Delta}}{m_\pi^2} T^j \epsilon_\Delta^* \cdot k' S_N(p + k) \gamma_5 \varphi_\rho^i ,
\] (C48)

\[
\bar{V}_b^{11} = \frac{f_{\pi NN} f_{\pi N\Delta}}{m_\pi^2} T^j \epsilon_\Delta^* \cdot k S_N(p - k') \gamma_5 \varphi_\rho^i ,
\] (C49)

\[
\bar{V}_c^{11} = i \frac{f_{\rho N\Delta} f_{\rho NN}}{m_\rho} \epsilon_{ij} T^l \left[ \epsilon_\Delta^* \cdot q \gamma_5 \gamma_5 - \epsilon_\Delta^* \cdot (k + k') \varphi_\rho^i \right] ,
\] (C50)

\[
\bar{V}_d^{11} = - \frac{f_{\pi \Delta N} f_{\pi N\Delta}}{m_\pi^2} [\epsilon_\Delta^*]_\mu \kappa' S_\Delta^i \gamma_5 T^j \gamma_5 \gamma_5 (p' + k') T^i k_{\nu} ,
\] (C51)

\[
\bar{V}_e^{11} = - \frac{f_{\pi \Delta N} f_{\pi N\Delta}}{m_\pi^2} [\epsilon_\Delta^*]_\mu \kappa' S_\Delta^i \gamma_5 (p - k') T^j k_{\nu} .
\] (C52)
12. \( \eta(k) + N(p) \rightarrow \pi'(k', j) + \Delta(p') \)

\[
V(12) = \frac{f_{\eta NN} f_{\eta N \Delta}}{m_\pi m_\eta} T^i \epsilon^*_\Delta \cdot k' S_N(p + k) \not{k}_5 \gamma_5 .
\] (C57)

13. \( \sigma(k) + N(p) \rightarrow \pi'(k', j) + \Delta(p') \)

\[
V(13) = -ig_{\sigma NN} \frac{f_{\pi N \Delta}}{m_\pi} T^i \epsilon^*_\Delta \cdot k' S_N(p + k) .
\] (C58)

14. \( \rho(k, i) + N(p) \rightarrow \pi'(k', j) + \Delta(p') \)

\[
\tilde{V}(14) = \tilde{V}_a^{14} + \tilde{V}_b^{14} + \tilde{V}_c^{14} + \tilde{V}_d^{14} ,
\] (C59)

with

\[
\tilde{V}_a^{14} = -i \frac{f_{\pi NN} g_{\rho NN}}{m_\pi} T^i \epsilon^*_\Delta \cdot k' S_N(p + k) \Gamma_\rho ,
\] (C60)

\[
\tilde{V}_b^{14} = i \frac{f_{\pi NN} f_{\rho NN}}{m_\pi m_\rho} T^i [\epsilon^*_\Delta \cdot k' \not{\epsilon}_\rho \gamma_5 - \epsilon^*_\Delta \cdot \epsilon_\rho \not{k}_5 \gamma_5] S_N(p + k') \not{k}'_5 \gamma_5 T^i ,
\] (C61)

\[
\tilde{V}_c^{14} = -i \frac{f_{\pi NN} f_{\rho NN}}{m_\pi m_\rho} [\epsilon^*_\Delta]_\alpha [\not{k}'_5 T^j T^i [\epsilon_\Delta]_\alpha k'_\beta S^\alpha_\Delta (p + k') [k_\beta \not{\epsilon}_\rho \gamma_5 - [\epsilon_\rho]_\beta \not{k}_5 \gamma_5] T^i ,
\] (C62)

\[
\tilde{V}_d^{14} = -i \frac{g_{\rho NN} f_{\pi NN}}{m_\pi} \epsilon^*_\Delta \left[ [\not{k}'_5 - \not{\epsilon}_\rho] k'_\beta \not{k}'_5 - [\epsilon_\rho]_\beta \not{k}_5 \gamma_5] T^i S^\alpha_\Delta (p - k') T^j k'_\beta ,
\] (C63)

15. \( \pi(k, i) + \Delta(p) \rightarrow \pi'(k', j) + \Delta'(p') \)

\[
\tilde{V}(15) = \tilde{V}_a^{15} + \tilde{V}_b^{15} + \tilde{V}_c^{15} + \tilde{V}_d^{14} ,
\] (C64)

with

\[
\tilde{V}_a^{15} = \left( \frac{f_{\pi NN}}{m_\pi} \right)^2 \epsilon^*_\Delta \cdot k' T^i S_N(p + k) \epsilon_\Delta \cdot k(T^i)^\dagger ,
\] (C65)

\[
\tilde{V}_b^{15} = \left( \frac{f_{\pi NN}}{m_\pi} \right)^2 [\not{k}'_5 T^i [\epsilon^*_\Delta]_\mu S^\mu_\Delta (p + k)[\epsilon_\Delta]_\nu \not{k}_5 T^i ,
\] (C66)

\[

\] (C67)

\[
\tilde{V}_d^{15} = ig_{\rho NN} g_{\rho \pi \pi} \left( \epsilon^*_\Delta \epsilon_\Delta \right) \left( \left( [k' + \not{k}_5] [k + \not{k}'] \not{q} - \not{q} (k' + \not{k}_5) \right) \right) \not{\epsilon}'_\Delta \cdot \epsilon_\Delta .
\] (C68)
16. \( \pi(k, i) + N(p) \rightarrow K(k') + \Lambda(p') \)

\[
\bar{V}(16) = \bar{V}_a^{16} + \bar{V}_b^{16} + \bar{V}_c^{16} + \bar{V}_d^{16} + \bar{V}_e^{16}, \tag{C69}
\]

with

\[
\bar{V}_a^{16} = \frac{f_{K\Lambda N} f_{\pi NN}}{m_K m_\pi} k' \gamma_5 S_N(p + k) \, k' \gamma_5 \tau^i, \tag{C70}
\]

\[
\bar{V}_b^{16} = f_{\pi \Sigma} f_{K \Sigma N} \frac{m_K}{m_\pi} k' \gamma_5 S_\Sigma(p - k') \, k' \gamma_5 \tau^i, \tag{C71}
\]

\[
\bar{V}_c^{16} = \frac{f_{\pi \Sigma} f_{K \Sigma N}}{m_K m_\pi} k_\alpha S_\Sigma^\alpha(p - k') k'_\beta \tau^i, \tag{C72}
\]

\[
\bar{V}_d^{16} = -g_{K* \Lambda \eta g_{K* K}} \frac{g_{\mu \nu} + q_\mu q_\nu/m_{K*}^2}{q^2 - m_{K*}^2} \left( \gamma^\mu - i \frac{\kappa_{K* \Lambda}}{m_N + m_\Lambda} \sigma_{\mu \nu} q_\nu \right) (k + k')^\rho \tau^i, \tag{C73}
\]

\[
\bar{V}_e^{16} = -g_{\kappa \Lambda \eta g_{K* K}} \frac{k \cdot k'}{q^2 - m_\kappa^2} \tau^i. \tag{C74}
\]

17. \( \eta(k) + N(p) \rightarrow K(k') + \Lambda(p') \)

\[
\bar{V}(17) = \bar{V}_a^{17} + \bar{V}_b^{17} + \bar{V}_c^{17} + \bar{V}_d^{17}, \tag{C75}
\]

with

\[
\bar{V}_a^{17} = \frac{f_{K\Lambda \eta} f_{\eta NN}}{m_K m_\eta} k' \gamma_5 S_N(p + k) \, k' \gamma_5, \tag{C76}
\]

\[
\bar{V}_b^{17} = \frac{f_{\eta \Lambda \Lambda} f_{K\Lambda N}}{m_K m_\eta} k' \gamma_5 S_\Lambda(p - k') \, k' \gamma_5, \tag{C77}
\]

\[
\bar{V}_c^{17} = -g_{K* \Lambda \eta g_{K* K}} \frac{g_{\mu \nu} + q_\mu q_\nu/m_{K*}^2}{q^2 - m_{K*}^2} \left( \gamma^\mu - i \frac{\kappa_{K* \Lambda}}{m_N + m_\Lambda} \sigma_{\mu \nu} q_\nu \right) (k + k')^\rho, \tag{C78}
\]

\[
\bar{V}_d^{17} = -g_{\kappa \Lambda \eta g_{K* K}} \frac{k \cdot k'}{m_\pi} \frac{q^2}{q^2 - m_\kappa^2}, \tag{C79}
\]

18. \( K(k) + \Lambda(p) \rightarrow K(k') + \Lambda(p') \)

\[
\bar{V}(18) = \bar{V}_a^{18} + \bar{V}_b^{18} + \bar{V}_c^{18} + \bar{V}_d^{18}, \tag{C80}
\]
with
\[ \mathcal{V}^{18}_a = \frac{f_{K\Lambda N}(k') f_{K\Lambda N}(k)}{m_K m_K} \gamma_5 S_N(p + k) \gamma_5 \gamma_5 , \]
\[ \mathcal{V}^{18}_b = \frac{f_{K\Xi}(k) f_{K\Xi}(k')}{m_K m_K} \gamma_5 S_\Xi(p - k') \gamma_5 \gamma_5 , \]
\[ \mathcal{V}^{18}_c = g_{\omega\omega\Lambda} g_{\omega\Lambda} \frac{-g_{\mu\rho} + q_{\mu} q_{\rho}/m^2_{\omega}}{q^2 - m^2_{\omega}} \left( \gamma^\mu - i \frac{K_{\omega\Lambda}}{2m_\Lambda} \sigma^{\mu\nu} q_\nu \right) (k + k')^\rho , \]
\[ \mathcal{V}^{18}_d = g_{\phi\phi\Lambda} g_{\phi\Lambda} \frac{-g_{\mu\rho} + q_{\mu} q_{\rho}/m^2_{\phi}}{q^2 - m^2_{\phi}} \left( \gamma^\mu - i \frac{K_{\phi\Lambda}}{2m_\Lambda} \sigma^{\mu\nu} q_\nu \right) (k + k')^\rho . \]

19. \( \pi(k, i) + N(p) \rightarrow K(k') + \Sigma(p', j) \)

\[ \mathcal{V}(19) = \mathcal{V}^{19}_a + \mathcal{V}^{19}_b + \mathcal{V}^{19}_c + \mathcal{V}^{19}_d + \mathcal{V}^{19}_e + \mathcal{V}^{19}_f , \]

with
\[ \mathcal{V}^{19}_a = \frac{f_{K\Sigma N} f_{\pi NN}}{m_K m_\pi} \gamma_5 \gamma_5 \tau^j S_N(p + k) \gamma_5 \gamma_5 \tau^i , \]
\[ \mathcal{V}^{19}_b = \frac{f_{\pi \Lambda \Sigma} f_{K\Lambda N}}{m_K m_\pi} \gamma_5 S_\Lambda(p - k') \gamma_5 \delta^{ij} , \]
\[ \mathcal{V}^{19}_c = \frac{f_{\pi \Sigma \Sigma} f_{K \Sigma N}}{m_K m_\pi} \gamma_5 S_\Sigma(p - k') \gamma_5 i c^{ijk} \tau_k , \]
\[ \mathcal{V}^{19}_d = \frac{f_{\pi \Sigma \Sigma} f_{K \Sigma N}}{m_K m_\pi} k_\alpha S_{\Sigma\Sigma} (p - k') k'_\beta i c^{ijk} \tau_k , \]
\[ \mathcal{V}^{19}_e = -g_{K^* N \Sigma} g_{K^* K} \frac{-g_{\mu\rho} + q_{\mu} q_{\rho}/m^2_{K^*}}{q^2 - m^2_{K^*}} \left( \gamma^\mu - i \frac{K_{K^* N \Sigma}}{m_N + m_\Sigma} \sigma^{\mu\nu} q_\nu \right) (k + k')^\rho \tau^i \tau^j , \]
\[ \mathcal{V}^{19}_f = \frac{-g_{K^* \Sigma N} g_{K^* \pi}}{m_\pi} \frac{k \cdot k'}{q^2 - m^2_{K^*}} \tau^i \tau^j . \]

20. \( \eta(k) + N(p) \rightarrow K(k') + \Sigma(p', j) \)

\[ \mathcal{V}(20) = \mathcal{V}^{20}_a + \mathcal{V}^{20}_b + \mathcal{V}^{20}_c + \mathcal{V}^{20}_d , \]

with
\[ \mathcal{V}^{20}_a = \frac{f_{K\Sigma N} f_{\eta NN}}{m_K m_\eta} \gamma_5 \gamma_5 S_N(p + k) \gamma_5 \gamma_5 \tau^j , \]
\[ \mathcal{V}^{20}_b = \frac{f_{\eta \Sigma \Sigma} f_{K \Sigma N}}{m_K m_\eta} \gamma_5 S_\Sigma(p - k') \gamma_5 \tau^i , \]
\[ \mathcal{V}^{20}_c = -g_{K^* N \Sigma} g_{K^* K} \frac{-g_{\mu\rho} + q_{\mu} q_{\rho}/m^2_{K^*}}{q^2 - m^2_{K^*}} \left( \gamma^\mu - i \frac{K_{K^* N \Sigma}}{m_N + m_\Sigma} \sigma^{\mu\nu} q_\nu \right) (k + k')^\rho \tau^j , \]
\[ \mathcal{V}^{20}_d = \frac{-g_{K^* \Sigma N} g_{K^* \pi}}{m_\pi} \frac{k \cdot k'}{q^2 - m^2_{K^*}} \tau^j . \]
21. \( K(k) + \Sigma(p, i) \rightarrow K(k') + \Lambda(p') \)

\[
\bar{V}(21) = \bar{V}_a^{21} + \bar{V}_b^{21} + \bar{V}_c^{21},
\]

with

\[ \bar{V}_a^{21} = \frac{f_{K\Lambda N}(k')f_{K\Sigma N}(k)}{m_K m_K} \not{k'}\gamma_5 S_N(p + k) \not{\gamma_5} \tau^i, \]

\[ \bar{V}_b^{21} = \frac{f_{K\Xi}(k)f_{K\Xi}(k')}{m_K m_K} \not{k'}\gamma_5 \tau^i S_{\Xi}(p - k') \not{k'} \gamma_5, \]

\[ \bar{V}_c^{21} = g_{\rho\Sigma} g_{\rho K} \frac{-g_{\rho\rho} + g_{\mu\rho} m_{\rho}^{2}}{q^2 - m_{\rho}^{2}} \left( \gamma^\mu - i \frac{\kappa_{\rho\Sigma}}{m_{\rho} + m_{\Delta}} \sigma^{\mu\nu} q^{\nu} \right) (k + k')^{\rho} \tau_i. \]

22. \( K(k) + \Sigma(p, i) \rightarrow K(k') + \Sigma(p', j) \)

\[
\bar{V}(21) = \bar{V}_a^{21} + \bar{V}_b^{21} + \bar{V}_c^{21} + \bar{V}_d^{21} + \bar{V}_e^{21},
\]

with

\[ \bar{V}_a^{21} = \frac{f_{K\Sigma N}(k')f_{K\Sigma N}(k)}{m_K m_K} \not{k'}\gamma_5 \tau^j S_N(p + k) \not{k'} \gamma_5 \tau^i, \]

\[ \bar{V}_b^{21} = \frac{f_{K\Xi}(k)f_{K\Xi}(k')}{m_K m_K} \not{k'}\gamma_5 \tau^j S_{\Xi}(p - k') \not{k'} \gamma_5, \]

\[ \bar{V}_c^{21} = g_{\omega\Sigma} g_{\omega K} \frac{-g_{\rho\rho} + g_{\rho\rho} m_{\rho}^{2}}{q^2 - m_{\rho}^{2}} \left( \gamma^\mu - i \frac{\kappa_{\rho\Sigma}}{2m_{\rho}} \sigma^{\mu\nu} q^{\nu} \right) (k + k')^{\rho} \delta^{ij}, \]

\[ \bar{V}_d^{21} = g_{\phi\Sigma} g_{\phi K} \frac{-g_{\rho\rho} + g_{\rho\rho} m_{\rho}^{2}}{q^2 - m_{\rho}^{2}} \left( \gamma^\mu - i \frac{\kappa_{\rho\Sigma}}{2m_{\rho}} \sigma^{\mu\nu} q^{\nu} \right) (k + k')^{\rho} \delta^{ij}, \]

\[ \bar{V}_e^{21} = g_{\rho\Sigma} g_{\rho K} \frac{-g_{\rho\rho} + g_{\rho\rho} m_{\rho}^{2}}{q^2 - m_{\rho}^{2}} \left( \gamma^\mu - i \frac{\kappa_{\rho\Sigma}}{2m_{\rho}} \sigma^{\mu\nu} q^{\nu} \right) (k + k')^{\rho} i\epsilon^{ijk} \tau_k. \]

The baryon propagators for the spin-1/2 octet baryon \( B \) and the spin-3/2 decuplet baryon \( D \) appearing in Eqs. (C8)-(C106) are given by

\[
S_B(p) = \frac{1}{p - m_B},
\]

\[
S_D^{\mu\nu}(p) = \frac{1}{3(p - m_D)} \left[ 2 \left( -g^{\mu\nu} + \frac{p^\mu p^\nu}{m_D^2} \right) + \frac{\gamma^{\mu} \gamma^{\nu} - \gamma^{\nu} \gamma^{\mu}}{2} - \frac{p^\mu p^\nu - p^{\nu} p^{\mu}}{m_D} \right].
\]

Equation (C108) is the simplest choice of many possible definitions of the spin-3/2 propagator. It is part of our phenomenology for this rather complex coupled-channels calculations.

Although the expressions (C8)-(C106) look like the usual Feynman amplitudes, the unitary transformation method defines definite procedures in evaluating the time component of each propagator. For each propagator, the vertex interactions associated
with its ends define either a “virtual” process or a “real” process. The real process is the process that can occur in free space such as $\Delta \rightarrow \pi N$. The virtual processes, such as the $\pi N \rightarrow N$, $\pi \Delta \rightarrow \Delta$, and $\pi \Delta \rightarrow N$ transitions, are not allowed by the energy-momentum conservation. The consequences of the unitary transformation is the following. When both vertex interactions are “virtual”, the propagator is the average of the propagators calculated with two different momenta specified by the initial and final external momenta. For example, the propagator of $\bar{\pi}$ of Eq. (C55), which corresponds to the $s$-channel $\pi + N(p) \rightarrow N \rightarrow \pi(k') + N(p')$, should be evaluated by

$$ S_N(p + k) \rightarrow \frac{1}{2}[S_N(p + k) + S_N(p' + k')] $$

$$ = \frac{1}{2} \left[ \frac{(E_N(p) + E_\pi(k))\gamma^0 - \vec{\gamma} \cdot \vec{k} + m_N}{(E_N(p) + E_\pi(k))^2 - (\vec{p} + \vec{k})^2 - m_N^2} + \frac{(E_N(p') + E_\pi(k'))\gamma^0 - \vec{\gamma} \cdot \vec{k'} + m_N}{(E_N(p') + E_\pi(k'))^2 - (\vec{p'} + \vec{k'})^2 - m_N^2} \right]. \quad (C109) $$

One sees clearly that the denominators of the above expression are independent of the collision energy $E$ of scattering equation and finite in all real momentum region. This is the essence of the unitary transformation method in deriving the interactions from Lagrangian. When only one of the vertex interactions is “real”, the propagator is evaluated by using the momenta associated with the “virtual” vertex. For example, the propagator of $V_a^\pi$ of Eq. (C55), which corresponds to the $s$-channel $\pi + N(p) \rightarrow \Delta \rightarrow \pi(k') + \Delta(p')$, is $S^\mu_\Delta(p' + k')$, but neither $S^\mu_\Delta(p + k)$ nor $[S^\mu_\Delta(p' + k') + S^\mu_\Delta(p + k)]/2$. We note that there is no propagator in Eqs. (C8)-(C106), which is attached by two real processes such as $\pi N \rightarrow \Delta \rightarrow \pi N$. Such real processes are included in the resonant term $I_{MB,M'B'}^E$ of Eq. (3).

**Appendix D: Matrix elements of $\gamma N \rightarrow MB$ transitions**

To include the final meson-baryon interactions in the photo-production, it is only necessary to perform the partial-wave decomposition of the final $MB$ state. We thus introduce the following helicity-LSJ mixed-representation

$$ v_{LS'M'B',J,q}^{J\pi}(k',q) = \sum_{\lambda_\pi \lambda_B} \sqrt{\frac{2L'+1}{2J+1}} \langle J_MJ_B'\lambda_\pi(-\lambda_B)|S'_{L+S'}R'|JS_z \rangle \times \langle J,\lambda_\pi \lambda_B(-\lambda_B)|v_{M'B',\gamma N}|J,q\lambda_\gamma(-\lambda_N) \rangle, \quad (D1) $$

where $\langle J,\lambda_\pi \lambda_B(-\lambda_B)|v_{M'B',\gamma N}|J,q\lambda_\gamma(-\lambda_N) \rangle$ can be evaluated using the same expression as Eq. (C2) but replacing $v_{M'B',MB}$ with $v_{M'B',\gamma N}$. To evaluate these quantities with our normalizations of states, we define for a photon four momentum $q = (\omega, \vec{q})$

$$ \langle (k'), p'|v_{MB,\gamma N}|q, p \rangle = \frac{1}{\sqrt{2q}}, \quad \sum_{n} J^\mu(n)\epsilon_\mu|q, p \rangle $$

$$ = \frac{1}{(2\pi)^2} \sum_{n} \sqrt{\frac{m_B}{E_B(k')}} \sqrt{\frac{1}{2E_M'(k')}} \bar{u}_B(\vec{p'})\epsilon I(n)u_N(\vec{p}) \sqrt{\frac{m_N}{E_N(q)}} \frac{1}{\sqrt{2q}}, \quad (D2) $$
where $\epsilon_\mu$ is the photon polarization vector, and $n$ denotes a given considered process

$$I(n) = \epsilon \cdot \bar{j}(n).$$  \hfill (D3)

Here $\bar{j}(n)$ can be constructed by using the Feynman rules. The resulting expressions for each of $\gamma N \rightarrow \pi N, \eta N, \sigma N, \rho N, \pi \Delta, K \Lambda, K \Sigma$ are listed below.

1. $\gamma(q) + N(p) \rightarrow \pi(k', j) + N(p')$

$$I(1) = I_a^1 + I_b^1 + I_c^1 + I_d^1 + I_e^1 + I_f^1 + I_g^1 + I_h^1,$$  \hfill (D4)

with

$$I_a^1 = +i \frac{f_{\pi NN}}{m_\pi} \frac{k' \gamma_5 \tau^j}{p' + k' - m_N} \Gamma_N,$$  \hfill (D5)

$$I_b^1 = +i \frac{f_{\pi NN}}{m_\pi} \frac{1}{p' - k' - m_N} (k' \gamma_5 \gamma^j),$$  \hfill (D6)

$$I_c^1 = +i \frac{f_{\pi NN}}{m_\pi} \Gamma_N \epsilon_{\gamma_5} \epsilon_j,$$  \hfill (D7)

$$I_d^1 = +i \frac{f_{\pi NN}}{m_\pi} \epsilon_{\gamma_5} \epsilon_j,$$  \hfill (D8)

$$I_e^1 = -i \frac{f_{\pi NN}}{m_\pi} \frac{k' \gamma_5}{k^2 - m_\pi^2} \epsilon_{\gamma_5} \epsilon_j,$$  \hfill (D9)

$$I_f^1 = -\frac{g_{\rho NN}g_{\rho NN}}{m_\pi} \frac{\gamma^j}{2} \left[ \gamma^\rho + \frac{k_\rho}{4m_N} (\gamma^\rho \kappa - \kappa^\rho) \right] \epsilon_{\alpha \beta \gamma \delta} \frac{1}{k^2 - m_\rho^2},$$  \hfill (D10)

$$I_g^1 = -\frac{g_{\omega NN}g_{\omega NN}}{m_\pi} \left[ \gamma^\rho + \frac{k_\rho}{4m_N} (\gamma^\rho \kappa - \kappa^\rho) \right] \epsilon_{\alpha \beta \gamma \delta} \frac{1}{k^2 - m_\omega^2},$$  \hfill (D11)

In the above equations, we have introduced $\kappa = p - p'$, $\Gamma_N = \bar{e}_N \gamma(\kappa_{NN}/4m_N) \gamma'/\xi - \gamma'\xi$, and $\Gamma_\mu \Delta = \Gamma_{\mu \nu} \epsilon_{\gamma j} \gamma^\nu$.

2. $\gamma(q) + N(p) \rightarrow \eta(k') + N(p')$

$$I(2) = I_a^2 + I_b^2 + I_c^2,$$  \hfill (D12)

with

$$I_a^2 = +i \frac{f_{\eta NN}}{m_\eta} \frac{k' \gamma_5}{p' + k' - m_N} \Gamma_N,$$  \hfill (D13)

$$I_b^2 = +i \frac{f_{\eta NN}}{m_\eta} \frac{1}{p' - k' - m_N} (k' \gamma_5),$$  \hfill (D14)

$$I_c^2 = -\frac{g_{\rho NN}g_{\rho NN}}{m_\rho} \frac{\gamma^\rho}{2} \left[ \gamma^\rho + \frac{k_\rho}{4m_N} (\gamma^\rho \kappa - \kappa^\rho) \right] \epsilon_{\mu \nu \alpha \beta} \frac{1}{k^2 - m_\rho^2}.$$

69
3. \( \gamma(q) + N(p) \rightarrow \sigma(k') + N(p') \)

\[
I(3) = I^3_a + I^3_b ,
\]

with

\[
I^3_a = -g_{\sigma NN} \frac{1}{p' + k' - m_N} \Gamma_N ,
\]

\[
I^3_b = -g_{\sigma NN} \Gamma_N \frac{1}{p' - k' - m_N} .
\]

4. \( \gamma(q) + N(p) \rightarrow \rho(k', j, \lambda) + N(p') \)

\[
I(4) = I^4_a + I^4_b + I^4_c + I^4_d + I^4_e + I^4_f + I^4_g ,
\]

with

\[
I^4_a = -g_{\rho NN} \Gamma_{\rho'} \frac{1}{p' + k' - m_N} \Gamma_N ,
\]

\[
I^4_b = -g_{\rho NN} \Gamma_N \frac{1}{p' - k' - m_N} \Gamma_{\rho'} ,
\]

\[
I^4_c = \frac{f_{\rho NN \Delta}}{m_\rho} (k'_{\mu} \rho'_{\mu} - k' \epsilon_{\rho' \mu}) \gamma_5 T^{ij} \gamma^\mu_5 (p' + k') \Gamma^\nu_\Delta ,
\]

\[
I^4_d = -\frac{f_{\rho NN \Delta}}{m_\rho} \Gamma_\nu \gamma^\mu_5 (p - k') T^{ij} (k'_{\nu} \rho'_{\nu} - k' \epsilon_{\nu' \nu}) \gamma_5 ,
\]

\[
I^4_e = \frac{g_{\rho NN K \rho}}{8 m_N} \gamma_\mu \gamma_\tau \gamma_\gamma \gamma_\rho \gamma_\mu \gamma_\tau \gamma_\gamma \gamma_\rho ,
\]

\[
I^4_f = \frac{g_{\rho NN \pi \gamma}}{2} \left[ \gamma_\mu + \frac{K_{\rho}}{2 m_\rho} \gamma_\mu \right] \times \left[ \epsilon^{\mu \nu}_\rho (k + k') \cdot \epsilon_\gamma - (k + k') \cdot \epsilon_\rho^* \right] \frac{\epsilon^{\alpha \beta}_\gamma k^\mu}{k^2 - m_\rho^2} ,
\]

\[
I^4_g = -\frac{f_{\pi NN g_{\rho NN}} \gamma_5}{m_\pi^2} \gamma_\tau \gamma^\gamma_5 \gamma_\alpha \gamma_\beta \gamma_\gamma \gamma_\rho \gamma_\mu k^\eta \epsilon_{\rho' \mu} \frac{1}{k^2 - m_\pi^2} .
\]

5. \( \gamma(q) + N(p) \rightarrow \pi(k', j) + \Delta(p') \)

\[
I(5) = I^5_a + I^5_b + I^5_c + I^5_d + I^5_e + I^5_f + I^5_g ,
\]
with

\[ I^5_a = +i \frac{f_{\pi N}}{m_\pi} \epsilon_\Delta \cdot q T^j S_N (p' + k') \Gamma_N , \]  
\[ I^5_b = +i \frac{f_{\pi N}}{m_\pi} \Gamma^m_\nu \epsilon_\Delta^m \epsilon^\nu_\Delta S_N (p - k') \gamma_5 T^j , \]  
\[ I^5_c = -i \frac{f_{\pi N}}{m_\pi} \epsilon_\Delta \cdot k' \gamma_5 T_s^j S_{\mu \nu} (p' + k') \Gamma_\nu \epsilon_\Delta , \]  
\[ I^5_d = +i \frac{f_{\pi N}}{m_\pi} \epsilon_\Delta^* \left( \frac{1}{2} + T^3 \right) [-g_\mu^\eta \eta \gamma^\rho + (\epsilon_\gamma) \eta \gamma^\rho] S_{\mu \nu} (p - k') k'^\nu T^j , \]  
\[ I^5_e = + i \frac{f_{\pi N}}{m_\pi} \epsilon_{ij3} T^i \epsilon_\gamma \cdot \epsilon_\Delta^* , \]  
\[ I^5_g = - \frac{f_{\pi N}}{m_\pi} \epsilon_{ij3} T^i [V^5_g + Z^5_g] , \]  
\[ I^5_g = - \frac{f_{\rho N}}{m_\pi} \epsilon_{ij3} T^i \left[ \frac{1}{k^2 - m_\rho^2} \epsilon_\Delta \cdot \epsilon_\Delta^* \gamma^\mu - \epsilon_\Delta \cdot \gamma^\mu \right] \gamma_5 \epsilon_\alpha \epsilon_\beta \epsilon_\gamma \epsilon_\eta \gamma_5 , \]

where the pion pole term \( I^5_g \) consists of energy independent interaction \( V^5_g \) and energy dependent interaction \( Z^5_g \) given as

\[ V^5_g = \frac{1}{2E_\pi (k' - q) E_\pi (q) - E_\Delta (k') - E_\pi (k' - q)} + \epsilon_\Delta \epsilon_\gamma , \]
\[ Z^5_g = \frac{1}{2E_\pi (k' - q) E - E_\pi (q) - E_\pi (k' - q)} + \epsilon_\gamma , \]

with \( k_1 = (E_\pi (k' - q), \vec{k'} - \vec{q}) \) and \( k_2 = (-E_\pi (k' - q), \vec{k'} - \vec{q}) \). The on-shell matrix element of \( V^5_g + Z^5_g \) is given as

\[ V^5 + Z^5 = \epsilon_\Delta \cdot \vec{k} (\vec{k} + k') \cdot \epsilon_\gamma \frac{1}{k^2 - m_\pi^2} . \]

6. \( \gamma(p) + N(p) \to K(k') + \Lambda(p') \)

\[ I(6) = I^6_a (1/2) + I^6_b + I^6_c + I^6_d + I^6_e + g^K_{K' K} T^6_f \quad \text{for} \quad \gamma p \to \Lambda K^+ \],
\[ = I^6_a (-1/2) + I^6_b - I^6_c + g^K_{K' K} T^6_f \quad \text{for} \quad \gamma n \to \Lambda K^0 \]
with

\[ I_a^6(t_N) = +i \frac{f_{K\Lambda}}{m_K} \not{p}' \gamma_5 \Sigma_N (p' + k') \Gamma_N (t_N) , \]  
\[ I_b^6 = +i \frac{f_{K\Lambda}}{m_K} \Gamma_\Lambda S_\Lambda (p - k') \not{p} \gamma_5 , \]  
\[ I_c^6 = +i \frac{f_{K\Sigma}}{m_K} \Gamma_\Sigma S_\Sigma (p - k') \not{p} \gamma_5 , \]  
\[ I_d^6 = -ie \frac{f_{K\Lambda}}{m_K} \not{\gamma} \gamma_5 , \]  
\[ I_e^6 = +ie \frac{f_{K\Lambda}}{m_K} \frac{\not{k} \gamma_5}{k^2 - m_K^2} (k + k') \cdot \epsilon_\gamma , \]  
\[ I_f^6 = -g_{K^*\Lambda} \frac{\not{k} \gamma_5}{m_K} \left[ \frac{\gamma^\delta + \frac{\kappa K^* \Lambda}{2(m_N + m_\Lambda)} (\gamma^\delta \not{k} - \not{k} \gamma^\delta)}{2} \right] \epsilon_{\alpha \beta \gamma \delta} q^\alpha q^\beta \frac{1}{k^2 - m_K^2} , \]  

where \( t_N = +(-)1/2 \) for the proton (neutron).

7. \( \gamma (q) + N (p) \rightarrow K (k') + \Sigma (p') \)

\[ I (7) = I_a^7 (1/2) + I_b^7 + I_c^7 + I_d^7 + I_e^7 + I_f^7 + I_g^7 (0) \]  
f for \( \gamma p \rightarrow \Sigma^0 K^+ \), \( \gamma p \rightarrow \Sigma^+ K^0 \), \( \gamma n \rightarrow \Sigma^- K^+ \), \( \gamma n \rightarrow \Sigma^0 K^0 \),

with

\[ I_a^7 (t_N) = +i \frac{f_{K\Sigma}}{m_K} \not{p}' \gamma_5 \Sigma_N (p' + k') \Gamma_N (t_N) , \]  
\[ I_b^7 = +i \frac{f_{K\Lambda}}{m_K} \Gamma_\Lambda S_\Lambda (p - k') \not{p} \gamma_5 , \]  
\[ I_c^7 = +i \frac{f_{K\Sigma}}{m_K} \Gamma_\Sigma S_\Sigma (p - k') \not{p} \gamma_5 , \]  
\[ I_d^7 = -ie \frac{f_{K\Lambda}}{m_K} \not{\gamma} \gamma_5 , \]  
\[ I_e^7 = +ie \frac{f_{K\Lambda}}{m_K} \frac{\not{k} \gamma_5}{k^2 - m_K^2} (k + k') \cdot \epsilon_\gamma , \]  
\[ I_f^7 = -g_{K^*\Lambda} \frac{\not{k} \gamma_5}{m_K} \left[ \frac{\gamma^\delta + \frac{\kappa K^* \Lambda}{2(m_N + m_\Lambda)} (\gamma^\delta \not{k} - \not{k} \gamma^\delta)}{2} \right] \epsilon_{\alpha \beta \gamma \delta} q^\alpha q^\beta \frac{1}{k^2 - m_K^2} , \]  
\[ I_g^7 (t_N) = +i \frac{f_{K\Sigma^*}}{m_K} \left[ \Gamma^\text{em,} (t_N) \right] \not{p} \gamma_5 (p - k') k_{\mu} , \]  

where \( \Gamma^\text{em,} (t_N) \) is the matrix element defined in Eq. \([B86]\), which contains \( G_{M,E,C}^{(\Sigma^*)} \) for \( t_\Sigma = 0 \) and \( G_{M,E,C}^{(\Sigma^*)} \) for \( t_\Sigma = \pm 1 \).
The isospin projections for the matrix elements are given as

\[ j_{1/2}^p = \frac{1}{\sqrt{3}} \langle K^+ \Sigma^0 | j | p \rangle - \frac{\sqrt{2}}{\sqrt{3}} \langle K^0 \Sigma^+ | j | p \rangle, \]  
(D57)

\[ j_{3/2}^p = \frac{\sqrt{2}}{\sqrt{3}} \langle K^+ \Sigma^0 | j | p \rangle + \frac{1}{\sqrt{3}} \langle K^0 \Sigma^+ | j | p \rangle, \]  
(D58)

\[ j_{1/2}^n = \frac{\sqrt{2}}{\sqrt{3}} \langle K^+ \Sigma^- | j | n \rangle - \frac{1}{\sqrt{3}} \langle K^0 \Sigma^0 | j | n \rangle, \]  
(D59)

\[ j_{3/2}^n = \frac{1}{\sqrt{3}} \langle K^+ \Sigma^- | j | n \rangle + \frac{\sqrt{2}}{\sqrt{3}} \langle K^0 \Sigma^0 | j | n \rangle. \]  
(D60)

Appendix E: Model parameters

In this Appendix, we list the model parameters determined by our global fits to the data of pion- and photon-induced \( \pi N \), \( \eta N \), \( K \Lambda \), and \( K \Sigma \) reactions in Tables XI-XVI.

TABLE XI. Masses appearing in the meson-exchange potentials. All the masses are kept as constant during the fit except for the \( \sigma \) and \( \kappa \) masses, \( m_\sigma \) and \( m_\kappa \).

| Mass   | (MeV) |
|--------|-------|
| \( m_N \) | 938.5 |
| \( m_\Lambda \) | 1115.7 |
| \( m_\Sigma \) | 1193.2 |
| \( m_\Xi \) | 1318.1 |
| \( m_\Delta \) | 1236.0 |
| \( m_\Sigma^* \) | 1385.0 |
| \( m_\pi \) | 138.5 |
| \( m_\eta \) | 547.5 |
| \( m_\kappa \) | 495.7 |
| \( m_\rho \) | 769.0 |
| \( m_\kappa^* \) | 893.9 |
| \( m_\omega \) | 782.6 |

TABLE XVI. Model parameters associated with the bare $\gamma N \to N^*$ helicity amplitudes defined in Eqs. (19)-(25). In the last column, fixed values of $M_{N^*}$ that are used for computing $q_R$ in Eq. (19) are presented. The helicity amplitudes $\tilde{A}_{1/2}$ and $\tilde{A}_{3/2}$ shown in the third and the fourth columns are $A_{1/2}$ and $A_{3/2}$ calculated at $q = m_\pi$, where $\tilde{M}_{N^*}$ and $\tilde{E}_{t^\pm}$ are obtained with the use of the relations in Eqs. (20)-(23). As for the 1st bare $P_{33}$ state [$P_{33}(1)$], we list the value of $x_{A_{1/2}}$ and $x_{A_{3/2}}$ in the columns of $\tilde{A}_{1/2}^{N^*}$ and $\tilde{A}_{3/2}^{N^*}$, respectively.

| $L_{212}$ | $\Lambda_{N^*}^{e.m.}$ (MeV) | $\tilde{A}_{1/2}^{N^*}$ ($10^{-3}$ GeV$^{-1/2}$) | $\tilde{A}_{3/2}^{N^*}$ ($10^{-3}$ GeV$^{-1/2}$) | $M_{N^*}$ (MeV) |
