(Dated: April 1, 2022)

In this paper, we present sufficient conditions for states to have positive distillable key rate. Exploiting the conditions, we show that the bound entangled states given by Horodecki et al. [Phys. Rev. Lett. 94, 160502 (2005), quant-ph/0506203] have nonzero distillable key rate, and finally exhibit new classes of bound entangled states with positive distillable key rate, but with negative Devetak-Winter lower bound of distillable key rate for the ccq states of their privacy squeezed versions.

I. INTRODUCTION

Quantum cryptography provides us with a perfectly secure cryptosystem, which is feasible in a practical way as well as in a theoretical way. In particular, quantum key distribution among quantum cryptographic protocols can be considered as one of the most important applications of quantum entanglement, since secure key distillation in quantum key distribution is closely related with entanglement distillation [1, 2].

It has been known that there are two different types of entanglement. One is called the free (or, distillable) entanglement, from which one can distill a pure entanglement useful for quantum communication by local quantum operation and classical communication (LOCC), and the other is called the bound (or, nondistillable) entanglement, which is not distillable. Even though one cannot distill a pure entanglement useful for quantum communication from the bound entanglement, it has been shown that any bound entangled states can be useful in quantum teleportation [3, 4]. Recently, Horodecki et al. [5, 6, 7] have shown that there are some classes of bound entangled states with positive key rate by showing that the lower bound $K_{DW}$ of distillable key rate introduced in [5, 6] is more than zero for those states.

However, the question of whether every entangled state has positive distillable key rate, $K_D > 0$, has still remained open. In this paper, we investigate the properties of quantum states with nonzero distillable key rate, and construct several sufficient conditions of $K_D > 0$. Exploiting the conditions, we show that the bound entangled states with positive partial transpose (PPT) given in [5, 6, 7] have nonzero distillable key rate, and finally present a new class of PPT bound entangled states satisfying $K_D > 0$, although $K_{DW}^D < 0$ for the ccq states of their privacy squeezed versions presented in [8].

This paper is organized as follows. In Sec. II we recall the concepts of private states and distillable key rate in [7]. In Sec. III we construct the sufficient conditions for states with $K_D > 0$. In Sec. IV we show that the PPT bound entangled states given in [6, 7, 8] have nonzero distillable key rate, and exhibit new classes of PPT bound entangled states satisfying $K_D > 0$, but $K_{DW}^D < 0$ for the ccq states of their privacy squeezed versions. Finally, in Sec. V we summarize our results.

II. PRIVATE STATES AND DISTILLABLE KEY RATE

For a positive integer $d ≥ 2$, a private state (or, pbit) $\gamma_{ABA'B'} = \gamma_{ABA'B'}$ on $\mathbb{C}^d^A \otimes \mathbb{C}^d^d \otimes \mathbb{C}^d^{A'} \otimes \mathbb{C}^d^{B'}$ with $d_A = d_B = d$, is defined as $\gamma_{ABA'B'} = U|\psi^+_d\rangle\langle\psi^-_d| \otimes \rho_{A'B'} U^\dagger$, where

$$|\psi^+_d\rangle = \frac{1}{\sqrt{d}} \sum_{k=0}^{d-1} |kk\rangle_{AB'},$$

$$\rho_{A'B'}$$ is an arbitrary state of the subsystem $A'B'$, and $U$ is an arbitrary twisting operation

$$U = \sum_{k,l=0}^{d-1} |kl\rangle\langle kl| \otimes U_{kl}$$

with unitary matrices $U_{kl}$. Then $\gamma_{ABA'B'}$ can be rewritten as

$$\gamma_{ABA'B'} = \frac{1}{d} \sum_{k,l=0}^{d-1} |kk\rangle\langle ll| \otimes U_{kl} \rho_{A'B'} U_{ll}^\dagger.$$ (3)

When $d = 2$, $\gamma_{ABA'B'}$ is called a private bit (or, pbit). Then we can have the following proposition [7].

**Proposition 1.** If a state $\rho = \sum_{i,j,k,l} |ij\rangle\langle kl| \otimes A_{ijkl}$ fulfills $\|A_{0011}\|_\infty ≥ 1/2 - \varepsilon$, then for $0 < \varepsilon < 1$ there exists a pbit $\gamma$ such that $\|\rho - \gamma\|_\infty ≤ \epsilon_0$.
$$\delta(\varepsilon)$$ with $$\delta(\varepsilon)$$ vanishing, when $$\varepsilon$$ approaches zero. More specifically,

$$\delta(\varepsilon) = \sqrt{\ln 2 \left( 8\sqrt{2\varepsilon} + h(2\sqrt{2\varepsilon}) \right) + 2\sqrt{2\varepsilon}},$$  

(4)

where $$h$$ is the binary entropy function.

Now, we define the distillable key rate $$K_D$$ as presented in [1]. Let $$\rho_{AB}$$ be a given state in $$\mathcal{B}(C^d_A \otimes C^d_B)$$. For each positive integer $$n$$, consider a sequence $$P_n$$ of LOCC operations such that $$P_n(\rho_{AB}^{\otimes n})$$ is a state in $$\mathcal{B}(C^{dn}_A \otimes C^{dn}_B)$$. The family of the operations $$\mathcal{P} = \{P_n : n \in \mathbb{N}\}$$ is called a pdit distillation protocol of $$\rho_{AB}$$ if

$$\lim_{n \to \infty} \|P_n(\rho_{AB}^{\otimes n}) - \gamma_{dn}\| = 0,$$  

(5)

where $$\gamma_{dn}$$ is a pdit whose $$AB$$ part is of dimension $$d_n^2$$. The rate of a protocol $$\mathcal{P}$$ is given by

$$R_P = \limsup_{n \to \infty} \frac{\log d_n}{n},$$  

(6)

and the distillable key rate of $$\rho_{AB}$$ is defined as the maximum rate of a protocol

$$K_D(\rho_{AB}) = \sup_{\mathcal{P}} R_P.$$  

(7)

Then the following proposition for the distillable key rate $$K_D$$ can be obtained, as shown in [3].

**Proposition 2.** If a state $$\rho$$ is close enough to a pdit in trace norm, then $$K_D(\rho) > 0$$.

### III. SUFFICIENT CONDITIONS FOR POSITIVE DISTILLABLE KEY RATE

Proposition 2 in Sec. III provides us with a simple sufficient condition of $$K_D(\rho) > 0$$, as follows.

**Lemma 1.** If one can transform, by LOCC, such as the recurrence protocol, sufficiently many copies of a state $$\rho$$ into a state close enough to a private state in trace norm, then $$K_D(\rho) > 0$$.

**Proof.** Assume that, by LOCC, the state of sufficiently many copies of $$\rho$$ is transformed into $$\rho'$$, which is close enough to a pdit in trace norm. Then, by Proposition 2, $$\rho'$$ has a nonzero distillable key rate, that is, $$K_D(\rho') > 0$$. Thus, by the definition of $$K_D$$, there exists a family of LOCC operations $$\mathcal{P}_0$$ such that

$$R_{\mathcal{P}_0} = \limsup_{n \to \infty} \frac{\log d_n}{n}$$  

(8)

is nonzero for $$\rho'$$. Now, let us consider $$K_D(\rho)$$ in accordance with $$K_D(\rho')$$. By the assumption, $$\rho'$$ can be made out of sufficiently many $$m$$ copies of $$\rho$$ by LOCC, which is denoted by $$P^m$$. We let $$\mathcal{P} = \{P \circ P' : P \in \mathcal{P}_0\}$$. Then $$\mathcal{P}$$ is a pdit distillation protocol of $$\rho$$, and hence we clearly obtain

$$K_D(\rho) \geq R_P = \limsup_{n \to \infty} \frac{\log d_n}{mn} = \frac{R_{\mathcal{P}_0}}{m} > 0.$$  

(9)

Therefore, this completes the proof.

By Lemma 1, we have an explicit form of a sufficient condition for $$K_D > 0$$.

**Theorem 1.** Let $$\rho$$ be any state in $$\mathcal{B}(C^2 \otimes C^2 \otimes C^d \otimes C^d)$$ with $$\rho = \sum_{i,j,k,l=0}^1 |ij\rangle\langle kl| \otimes \rho_{ijkl}$$. If $$\|A_{0000}\| = \|A_{0011}\| = \|A_{1111}\|$$ and $$\|A_{0101}\| < \|A_{0011}\|, \|A_{1010}\| < \|A_{1111}\|$$, then $$K_D(\rho) > 0$$.

**Proof.** Repeating the recurrence protocol on many copies of $$\rho$$, by Lemma 3 in Appendix, we can obtain

$$\rho' = \frac{1}{N} \left[ \begin{array}{cccc} A_{0000}^{\otimes n} & A_{0011}^{\otimes n} & A_{0101}^{\otimes n} & A_{0111}^{\otimes n} \\ A_{0100}^{\otimes n} & A_{0101}^{\otimes n} & A_{0110}^{\otimes n} & A_{0111}^{\otimes n} \\ A_{1000}^{\otimes n} & A_{1001}^{\otimes n} & A_{1010}^{\otimes n} & A_{1011}^{\otimes n} \\ A_{1100}^{\otimes n} & A_{1101}^{\otimes n} & A_{1110}^{\otimes n} & A_{1111}^{\otimes n} \end{array} \right],$$  

(10)

where $$N = \|A_{0000}\|^n + \|A_{0101}\|^n + \|A_{1010}\|^n + \|A_{1111}\|^n$$. Then we have $$\|A_{0011}\| = \|A_{0011}\|^n/N$$, where $$A_{0011}$$ is the upper-right block of $$\rho'$$.

Since $$\|A_{0000}\| = \|A_{0011}\| = \|A_{1111}\|, \|A_{0101}\| < \|A_{0011}\|$$, and $$\|A_{1010}\| < \|A_{0011}\|$$, we can readily show that $$\|A_{0011}\|$$ converges to 1/2 as $$n$$ tends to infinity. Therefore, by Proposition 2 and Lemma 1, we conclude that $$K_D(\rho)$$ is positive.

By Theorem 1, we clearly obtain the following corollary.

**Corollary 1.** Let $$\rho$$ be a state in $$\mathcal{B}(C^2 \otimes C^2 \otimes C^d \otimes C^d)$$ of the form

$$\rho = |\phi^+\rangle\langle\phi^+| \otimes \sigma_0 + |\phi^-\rangle\langle\phi^-| \otimes \sigma_1 + |\psi^+\rangle\langle\psi^+| \otimes \sigma_2 + |\psi^-\rangle\langle\psi^-| \otimes \sigma_3,$$  

(11)

where $$|\phi^\pm\rangle$$ and $$|\psi^\pm\rangle$$ are Bell states in $$C^2 \otimes C^2$$. Then if $$\|\sigma_0 - \sigma_1\| > 1/2$$ and tr($$\sigma_0\sigma_1$$) = 0, then $$K_D(\rho) > 0$$.

**Proof.** $$\rho$$ has the following matrix form:

$$\rho = \frac{1}{2} \left[ \begin{array}{cccc} 0 & 0 & 0 & \sigma_0 - \sigma_1 \\ 0 & \sigma_0 + \sigma_1 & 0 & 0 \\ 0 & 0 & \sigma_0 + \sigma_1 & 0 \\ \sigma_0 - \sigma_1 & 0 & 0 & \sigma_0 + \sigma_1 \end{array} \right].$$  

(12)

By Lemma 4 in Appendix, we have $$\|\sigma_0 - \sigma_1\| = \|\sigma_0 + \sigma_1\|$$, and hence $$\|\sigma_2 + \sigma_3\| < 1/2 < \|\sigma_0 + \sigma_1\|$$, Therefore, since all the hypotheses in Theorem 1 are satisfied, we conclude that $$K_D(\rho) > 0$$.

Now, let us consider the privacy squeezed state $$\sigma_{AB}$$ of $$\rho$$ in Eq. (11), which has been introduced in [4, 8], is

$$\sigma_{AB} = \frac{1}{2} \left[ \begin{array}{cccc} \|\sigma_0 + \sigma_1\| & 0 & 0 & \|\sigma_0 - \sigma_1\| \\ 0 & \|\sigma_2 + \sigma_3\| & \|\sigma_2 - \sigma_3\| & 0 \\ 0 & \|\sigma_2 - \sigma_3\| & \|\sigma_2 + \sigma_3\| & 0 \\ \|\sigma_0 - \sigma_1\| & 0 & 0 & \|\sigma_0 + \sigma_1\| \end{array} \right].$$  

(13)
and let $|\Psi_{ABE}\rangle$ be a purification of $\sigma_{AB}$. Then

$$|\Psi_{ABE}\rangle = \sqrt{x} |\phi^+\rangle e_0 + \sqrt{y} |\phi^-\rangle e_1 + \sqrt{z} |\psi^+\rangle e_2 + \sqrt{w} |\psi^-\rangle e_3$$

$$= \frac{1}{2} (|00\rangle \otimes (\sqrt{x} |e_0\rangle + \sqrt{y} |e_1\rangle) + |11\rangle \otimes (\sqrt{z} |e_2\rangle + \sqrt{w} |e_3\rangle) + |01\rangle \otimes (\sqrt{z} |e_2\rangle - \sqrt{w} |e_3\rangle) + |10\rangle \otimes (\sqrt{z} |e_2\rangle - \sqrt{w} |e_3\rangle),$$

where

$$x = \frac{1}{2} (\|\sigma_0 + \sigma_1\| + \|\sigma_0 - \sigma_1\|),$$

$$y = \frac{1}{2} (\|\sigma_0 + \sigma_1\| - \|\sigma_0 - \sigma_1\|),$$

$$z = \frac{1}{2} (\|\sigma_2 + \sigma_3\| + \|\sigma_2 - \sigma_3\|),$$

$$w = \frac{1}{2} (\|\sigma_2 + \sigma_3\| - \|\sigma_2 - \sigma_3\|).$$

By simple calculations, we can know that the ccq state $\sigma_{ABE}^{ccq}$ of $|\Psi_{ABE}\rangle$ is

$$\sigma_{ABE}^{ccq} = \frac{1}{2} \sum_{ij=0}^{1} |ij\rangle \langle ij| \otimes P_{ij},$$

where $P_{00}$, $P_{11}$, $P_{01}$, and $P_{10}$ are the projections onto the subspaces spanned by $\sqrt{x} |e_0\rangle + \sqrt{y} |e_1\rangle$, $\sqrt{x} |e_0\rangle - \sqrt{y} |e_1\rangle$, $\sqrt{z} |e_2\rangle + \sqrt{w} |e_3\rangle$, and $\sqrt{z} |e_2\rangle - \sqrt{w} |e_3\rangle$, respectively.

We note that one can get $K_D^{DW} = I(A:B) - I(A:E)$ bits of key for the ccq state obtained from the state $|\Psi_{ABE}\rangle$ by Devetak-Winter protocol, where $I(A:B) = S(A) + S(B) - S(AB)$, $S$ being von Neumann entropy. Therefore, by straightforward calculations, one can obtain

$$K_D^{DW} (\sigma_{ABE}^{ccq}) = 1 - S(E),$$

and

$$S(E) = -x \log_2 x - y \log_2 y - z \log_2 z - w \log_2 w.$$ 

Hence, we obtain the following lemma.

**Lemma 2.** Let $\rho$ be a state in $B(C^2 \otimes C^2 \otimes C^d \otimes C^d)$ of the form in Eq. (11), and let $\sigma_{ABE}^{ccq}$ be the ccq state obtained from the privacy squeezed state of $\rho$. Then $K_D^{DW} (\sigma_{ABE}^{ccq}) = 1 - S(E)$, and furthermore,

$$S(E) = -x \log_2 x - y \log_2 y - z \log_2 z - w \log_2 w,$$

where $x$, $y$, $z$, and $w$ are in Eq. (15).

We now present another sufficient condition of $K_D > 0$, which is a generalization of a result of Horodecki et al. (Proposition 1 in [1]).

**Theorem 2.** Let $\rho$ be any state in $B(C^2 \otimes C^2 \otimes C^d \otimes C^d)$ with $\rho = \sum_{i,j,k,l=0}^{1} |ij\rangle \langle kl| \otimes A_{ijkl}$, and let

$$x = (\|A_{0000}\| + \|A_{1111}\|)/2 + \|A_{0011}\|,$$

$$y = (\|A_{0000}\| + \|A_{1111}\|)/2 - \|A_{0011}\|,$$

$$z = (\|A_{0101}\| + \|A_{1010}\|)/2 + \|A_{0101}\|,$$

$$w = (\|A_{0101}\| + \|A_{1010}\|)/2 - \|A_{0101}\|.$$

If $-x \log_2 x - y \log_2 y - z \log_2 z - w \log_2 w < 1$, then $K_D(\rho) > 0$. More specifically,

$$K_D(\rho) \geq 1 + x \log_2 x + y \log_2 y + z \log_2 z + w \log_2 w > 0.$$ 

**Proof.** $\rho$ has the matrix form

$$\rho = \begin{bmatrix} A_{0000} & A_{0001} & A_{0010} & A_{0011} \\ A_{0100} & A_{0101} & A_{0110} & A_{0111} \\ A_{1000} & A_{1001} & A_{1010} & A_{1011} \\ A_{1100} & A_{1101} & A_{1110} & A_{1111} \end{bmatrix}.$$ 

If we apply an appropriate twisting operation first, then we can get

$$\rho_{tw} = \begin{bmatrix} B_{0000} & B_{0001} & B_{0010} & B_{0011} \\ B_{0100} & B_{0101} & B_{0110} & B_{0111} \\ B_{1000} & B_{1001} & B_{1010} & B_{1011} \\ B_{1100} & B_{1101} & B_{1110} & B_{1111} \end{bmatrix},$$

where $B_{0000}$, $B_{0111}$, $B_{0011}$, $B_{0100}$, $B_{0101}$, $B_{1010}$, and $B_{1001}$ are positive and

$$\text{tr}B_{0000} = \|A_{0000}\|, \quad \text{tr}B_{0011} = \|A_{1111}\|,$$

$$\text{tr}B_{0011} = \|A_{0011}\|, \quad \text{tr}B_{0100} = \|A_{1100}\|,$$

$$\text{tr}B_{0101} = \|A_{0101}\|, \quad \text{tr}B_{1010} = \|A_{1010}\|,$$

$$\text{tr}B_{0110} = \|A_{0110}\|, \quad \text{tr}B_{1001} = \|A_{1001}\|. $$

By the same LOCC on the subsystem $AB$ as the depolarization in $C^d \otimes C^d$, we can get the following state

$$\tilde{\rho}_{tw} = \begin{bmatrix} B_{0000} + B_{0111} & 0 & 0 & 0 \\ 0 & B_{0000} + B_{0110} & 0 & 0 \\ 0 & 0 & B_{0011} + B_{0100} & 0 \\ 0 & 0 & 0 & B_{0000} + B_{0111} \end{bmatrix}. $$

Let $\sigma_{tw}^{ccq}$ be the privacy squeezed state of $\tilde{\rho}_{tw}$, and $\sigma_{ABE}^{ccq}$ be the ccq state obtained from $\sigma_{tw}^{ccq}$. We remark that the distillable key rate of $\rho_{tw}$ is the same as that of the original state $\rho$, and furthermore $\sigma_{ABE}^{ccq}$ has the key rate no better than that of $\rho_{tw}$ [1]. Since $\tilde{\rho}_{tw}$ is of the form in Eq. (11), for $x$, $y$, $z$, and $w$ in Eq. (20), we straightforwardly obtain

$$K_D^{DW} (\sigma_{ABE}^{ccq}) = 1 - S(E),$$

and

$$S(E) = -x \log_2 x - y \log_2 y - z \log_2 z - w \log_2 w,$$

by Lemma 2. Since $-x \log_2 x - y \log_2 y - z \log_2 z - w \log_2 w < 1$ by our hypothesis, we have

$$K_D(\rho) \geq K_D^{DW} (\sigma_{ABE}^{ccq}) = 1 - S(E) > 0.$$ 

$$\square$$
IV. EXAMPLES

We first consider the PPT states with $K_D > 0$ presented in [3, 6].

**Example 1.** Let $\varrho_a = 2P_{sym}/(d^2 + d)$ and $\varrho_a = 2P_{as}/(d^2 - d)$ with the symmetric projector $P_{sym}$ and the antisymmetric projector $P_{as}$ on $\mathbb{C}^d \otimes \mathbb{C}^d$, and

$$\rho = \frac{1}{2} \begin{bmatrix} p(\tau_1 + \tau_0) & 0 & 0 & p(\tau_1 - \tau_0) \\ 0 & (1 - 2p)\tau_0 & 0 & 0 \\ 0 & 0 & (1 - 2p)\tau_0 & 0 \\ p(\tau_1 - \tau_0) & 0 & 0 & p(\tau_1 + \tau_0) \end{bmatrix},$$

where $\tau_0 = \varrho_a \otimes I$ and $\tau_1 = [(\varrho_a + \varrho_\sigma)/2] \otimes I$. Then we can obtain

$$\rho' = \frac{1}{2^{mN}} \begin{bmatrix} [p(\tau_1 + \tau_0)]^{\otimes m} & 0 & 0 & [p(\tau_1 - \tau_0)]^{\otimes m} \\ 0 & [(1 - 2p)\tau_0]^{\otimes m} & 0 & 0 \\ 0 & 0 & [(1 - 2p)\tau_0]^{\otimes m} & 0 \\ [p(\tau_1 - \tau_0)]^{\otimes m} & 0 & 0 & [p(\tau_1 + \tau_0)]^{\otimes m} \end{bmatrix},$$

(29)

with $N = 2p^m + 2(1/2 - p)^m$, from $\rho$ by the recurrence protocol. Then it follows from Lemma 3 in Appendix that the state $\rho$ is PPT for $p \in [0, 1/3]$ and $(1 - p)/p \geq \lceil d/(d - 1) \rceil^l$, and hence the state $\rho'$ is also PPT.

Let

$$x = \frac{1}{2^{mN}} \|[p(\tau_1 + \tau_0)]^{\otimes m} + [p(\tau_1 - \tau_0)]^{\otimes m}\|,$$

$$y = \frac{1}{2^{mN}} \|[p(\tau_1 + \tau_0)]^{\otimes m} - [p(\tau_1 - \tau_0)]^{\otimes m}\|,$$

$$z = w = \frac{1}{2^{mN}} \|(1 - 2p)\tau_0\|^{\otimes m}.$$

Then for $p \in (1/4, 1/3]$, by choosing sufficiently large $m$ and $l$, we have $-x \log_2 x - y \log_2 y - z \log_2 z - w \log_2 w < 1$. Therefore, we can obtain the PPT states with $K_D > 0$ by Theorem 2.

We consider the low-dimensional PPT states with $K_D > 0$ presented in [3].

**Example 2.** For two private bits $\gamma_1$ and $\gamma_2$, take any biased mixture of the form:

$$\rho = p_1\gamma_1 + p_2\sigma_x^A \gamma_2 \sigma_x^A$$

(31)

with $p_1 > p_2$ and $\sigma_x^A = [\sigma_x]_A \otimes I_{A'BB'}$, where $\sigma_x$ is one of Pauli matrices representing the bit flip. Then $\rho$ has the following matrix form:

$$\rho = \frac{1}{2} \begin{bmatrix} p_1 \sqrt{X_1 X_1^\dagger} & 0 & 0 & p_1 X_1 \\ 0 & p_2 \sqrt{X_2 X_2^\dagger} & p_2 X_2 & 0 \\ 0 & p_2 X_2^\dagger & p_2 \sqrt{X_2^\dagger X_2} & 0 \\ p_1 X_1^\dagger & 0 & 0 & p_1 \sqrt{X_1^\dagger X_1} \end{bmatrix}$$

(32)

and let $\Gamma$ denote partial transposition over the subsystem $BB'$. Then we have $tr(\sigma_0 \sigma_1) = 0$,

$$\sigma_0 + \sigma_1 = \rho \mathcal{I} = \sigma_0^\Gamma + \sigma_1^\Gamma,$$

$$\sigma_0 - \sigma_1 = \rho \langle 01|01 \rangle + |11\rangle\langle 11| + |01\rangle\langle 01| - |10\rangle\langle 10|,$$

$$\langle 01\rangle\langle 01| + |10\rangle\langle 10| + |01\rangle\langle 01| - |10\rangle\langle 10|,$$

for some orthonormal $|\xi_0\rangle$ and $|\xi_1\rangle$ with

$$|\xi_0\rangle\langle 01| + |\xi_1\rangle\langle 11| = |01\rangle\langle 01| + |10\rangle\langle 10|.$$

(36)

Now, let

$$\rho = |\phi^+\rangle\langle \phi^+| \otimes \sigma_0 + |\phi^-\rangle\langle \phi^-| \otimes \sigma_1$$

$$+ |\psi^+\rangle\langle \psi^+| \otimes \sigma_2 + |\psi^-\rangle\langle \psi^-| \otimes \sigma_3,$$

(37)
where
\[ \sigma_2 = \sqrt{2p}|\xi_0\rangle\langle\xi_0| + q|00\rangle\langle00|, \]
\[ \sigma_3 = \sqrt{2p}|\xi_1\rangle\langle\xi_1| + |00\rangle\langle00|. \] (38)
Then \( \|\sigma_0 - \sigma_1\| = 4p > 1/2 \), and it follows from Corollary 1 that \( K_D(\rho) > 0 \).

Since
\[ \sigma_2 - \sigma_3 = (\sigma_0 - \sigma_1)^\Gamma, \]
\[ \sigma_2 + \sigma_3 = \sqrt{2p}(|\xi_0\rangle\langle\xi_0| + |\xi_1\rangle\langle\xi_1|) + 2q|00\rangle\langle00| \]
\[ = \sqrt{2p}(|01\rangle\langle01| + |10\rangle\langle10|) + 2q|00\rangle\langle00| \]
\[ = (\sigma_2 + \sigma_3)^\Gamma, \] (39)
\( \rho^\Gamma = \rho \), that is, \( \rho \) has PPT. Therefore, \( \rho^\prime \)’s are the PPT states with positive distillable key.

However, since the values \( x, y, z, \) and \( w \) in Theorem 2 are \( x = 4p, y = 0, z = 2\sqrt{2p} + q, \) and \( w = q \),
\[ K_D^{\text{DW}}(\sigma_{\text{ccq}}) = 1 + 4p \log_2 4p + q \log_2 q \]
\[ + (2\sqrt{2p} + q) \log_2(2\sqrt{2p} + q) \] (40)
is not always positive for \( 0 < q < (2 - \sqrt{2})/8 \) as seen in Fig. 1, where \( \sigma_{\text{ccq}}^{\text{cc}} \) is the ccq state for the privacy squeezed state of \( \rho \). Therefore, when \( K_D^{\text{DW}} < 0 \), by means of Theorem 2, one cannot determine whether \( \rho \) has positive distillable key rate or not, although one can readily show that \( K_D(\rho) > 0 \) by Corollary 1.

We now present another PPT states with \( K_D > 0 \) but \( K_D^{\text{DW}} < 0 \) for the ccq states of their privacy squeezed states.

Example 4. Let
\[ \rho = \frac{1}{2} \begin{bmatrix} \sigma_0 + \sigma_1 & 0 & 0 & \sigma_0 - \sigma_1 \\ 0 & 2\sigma_2 & 0 & 0 \\ 0 & 0 & 2\sigma_2 & 0 \\ \sigma_0 - \sigma_1 & 0 & 0 & \sigma_0 + \sigma_1 \end{bmatrix}, \] (41)
where
\[ \sigma_0 = p(|\phi^+\rangle\langle\phi^+| + |01\rangle\langle01|), \]
\[ \sigma_1 = p(|\phi^-\rangle\langle\phi^-| + |10\rangle\langle10|), \]
\[ \sigma_2 = \frac{p}{\sqrt{2}}(|01\rangle\langle01| + |10\rangle\langle10|) \]
\[ + \frac{q}{2}|00\rangle\langle00| + \frac{q}{2}|11\rangle\langle11|, \] (42)
with \( p = (1 - 2q)/(4 + 2\sqrt{2}) \) for \( 0 \leq q < (2 - \sqrt{2})/8 \).

Then since
\[ \sigma_2 - \sigma_3 = \frac{1}{2} \begin{bmatrix} \sigma_0^\Gamma + \sigma_1^\Gamma & 0 & 0 & 0 \\ 0 & 2\sigma_2^\Gamma & \sigma_0^\Gamma - \sigma_1^\Gamma & 0 \\ 0 & \sigma_0^\Gamma - \sigma_1^\Gamma & 2\sigma_2^\Gamma & 0 \\ 0 & 0 & 0 & \sigma_0^\Gamma + \sigma_1^\Gamma \end{bmatrix}, \] (43)
and \( 2\sigma_2^\Gamma + (\sigma_0^\Gamma - \sigma_1^\Gamma) \) is positive, \( \rho \) is a PPT state by Lemma 3 in Appendix. Since \( \rho \) satisfies all conditions of Theorem 1 and therefore \( K_D(\rho) > 0 \).

However, as in Example 3 we can see that \( K_D^{\text{DW}} < 0 \) for the ccq states of their privacy squeezed states. More precisely, one can obtain that
\[ K_D^{\text{DW}} = 1 + 4p \log_2 4p \]
\[ + 2(\sqrt{2p} + q) \log_2(\sqrt{2p} + q) \] (44)
is negative for all \( 0 < q < (2 - \sqrt{2})/8 \), as seen in Fig. 1.

V. SUMMARY

We have investigated properties of quantum states with positive distillable key rate, and have constructed sufficient conditions for states to have positive distillable key rate. Exploiting the conditions, we have shown that the PPT bound entangled states given by Horodecki et al. have nonzero distillable key rate, and have exhibited a new class of PPT bound entangled states with \( K_D > 0 \), but with \( K_D^{\text{DW}} < 0 \) for the ccq states of their privacy squeezed versions.

APPENDIX: SIMPLE LEMMAS

In this appendix, we present some simple but useful lemmas.
Lemma 3. Let $A$ and $B$ be $n \times n$ hermitian matrices. Then $\begin{bmatrix} A & B \\ B & A \end{bmatrix}$ is positive if and only if $A \pm B$ is positive.

Proof. Let $x$ and $y$ be any vector in $\mathbb{C}^n$. Then we have

\[
\begin{bmatrix} x^\dagger & y^\dagger \end{bmatrix} \begin{bmatrix} A & B \\ B & A \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = x^\dagger Ax + y^\dagger Ay + x^\dagger By + y^\dagger Bx = \frac{1}{2} \left( x^\dagger + y^\dagger \right) \left( A + B \right) \left( x + y \right) + \frac{1}{2} \left( x^\dagger - y^\dagger \right) \left( A - B \right) \left( x - y \right).
\]

(A.1)

Therefore, we can clearly obtain the proof of this lemma from Eq. (A.1).

Lemma 4. For any two positive operators $\sigma_0$ and $\sigma_1$, $\| \sigma_0 - \sigma_1 \| = \| \sigma_0 + \sigma_1 \|$ if and only if $\text{tr}(\sigma_0 \sigma_1) = 0$.

Proof. If $\text{tr}(\sigma_0 \sigma_1) = 0$, then it is trivial that $\| \sigma_0 - \sigma_1 \| = \| \sigma_0 + \sigma_1 \|$. We now assume that $\| \sigma_0 - \sigma_1 \| = \| \sigma_0 + \sigma_1 \|$. Note that there exist positive operators $\tau_0$ and $\tau_1$ such that $\sigma_0 - \sigma_1 = \tau_0 - \tau_1$ and $\text{tr}(\tau_0 \tau_1) = 0$. Then from the following equalities

\[
\text{tr}(\sigma_0) - \text{tr}(\sigma_1) = \text{tr}(\tau_0 - \tau_1) = \text{tr}(\tau_0) - \text{tr}(\tau_1),
\]

(A.2)

and

\[
\text{tr}(\sigma_0) + \text{tr}(\sigma_1) = \| \sigma_0 + \sigma_1 \| = \| \sigma_0 - \sigma_1 \| = \| \tau_0 - \tau_1 \| = \text{tr}(\tau_0) + \text{tr}(\tau_1),
\]

(A.3)

we obtain $\text{tr}(\sigma_0) = \text{tr}(\tau_0)$ and $\text{tr}(\sigma_1) = \text{tr}(\tau_1)$. Since $\text{tr}(\tau_0 \tau_1) = 0$, there exist two disjoint index sets $I_0$, $I_1$, and an orthonomal basis $\{ x_j : j \in I_0 \cup I_1 \}$ such that $\tau_0 = \sum_{j \in I_0} \lambda_j \langle x_j | x_j \rangle$ and $\tau_1 = \sum_{j \in I_1} \lambda_j \langle x_j | x_j \rangle$ for some $\lambda_j \geq 0$. Then it is straightforward to have the following equalities.

\[
\sum_{j \in I_0} \langle x_j | \sigma_0 | x_j \rangle - \sum_{j \in I_0} \langle x_j | \sigma_1 | x_j \rangle = \sum_{j \in I_0} \langle x_j | \tau_0 - \tau_1 | x_j \rangle = \sum_{j \in I_0} \langle x_j | \tau_0 | x_j \rangle - \sum_{j \in I_0} \langle x_j | \tau_1 | x_j \rangle = \sum_{j \in I_0} \langle x_j | \tau_0 | x_j \rangle - \sum_{j \in I_0 \cup I_1} \langle x_j | \tau_0 | x_j \rangle = \text{tr}(\tau_0) = \text{tr}(\sigma_0)
\]

and

\[
\sum_{j \in I_0} \langle x_j | \sigma_0 | x_j \rangle + \sum_{j \in I_1} \langle x_j | \sigma_1 | x_j \rangle = \sum_{j \in I_0 \cup I_1} \langle x_j | \tau_0 | x_j \rangle = \text{tr}(\tau_0) = \text{tr}(\sigma_0).
\]

Hence, we obtain

\[
\sum_{j \in I_0} \langle x_j | \sigma_0 | x_j \rangle + \sum_{j \in I_0} \langle x_j | \sigma_1 | x_j \rangle = 0.
\]

(A.5)

Since $\sigma_0$ and $\sigma_1$ are positive, it can be obtained that $\langle x_j | \sigma_0 | x_j \rangle = 0$ for any $j \in I_1$, and $\langle x_j | \sigma_1 | x_j \rangle = 0$ for any $j \in I_0$. Therefore, we conclude that $\text{tr}(\sigma_0 \sigma_1) = 0$.

Now, we consider the recurrence protocol for distillation a pbit $[0 \ 1]$. By simple but tedious calculations, we obtain the following lemma.

Lemma 5 (Recurrence protocol). For any states $\rho_1$ and $\rho_2$ in $\mathcal{B}(\mathbb{C}^2 \otimes \mathbb{C}^2 \otimes \mathbb{C}^d \otimes \mathbb{C}^d)$, let

\[
\rho_1 = \begin{bmatrix} A_{0000} & A_{0001} & A_{0010} & A_{0011} \\ A_{0100} & A_{0101} & A_{0110} & A_{0111} \\ A_{1000} & A_{1001} & A_{1010} & A_{1011} \\ A_{1100} & A_{1101} & A_{1110} & A_{1111} \end{bmatrix},
\]

(A.6)

and

\[
\rho_2 = \begin{bmatrix} B_{0000} & B_{0001} & B_{0010} & B_{0011} \\ B_{0100} & B_{0101} & B_{0110} & B_{0111} \\ B_{1000} & B_{1001} & B_{1010} & B_{1011} \\ B_{1100} & B_{1101} & B_{1110} & B_{1111} \end{bmatrix}.
\]

(A.7)

After some LOCC operations in the recurrence protocol, $\rho_1 \otimes \rho_2$ can be transformed into a state in $\mathcal{B}(\mathbb{C}^2 \otimes \mathbb{C}^2 \otimes \mathbb{C}^d \otimes \mathbb{C}^d)$. Let $\rho_{jj}$ be the resulting state when the measurement outcome is $jj$. Then we have
\[ \rho_{00} = \frac{1}{N_0} \begin{bmatrix} A_{0000} \otimes B_{0000} & A_{0001} \otimes B_{0001} & A_{0010} \otimes B_{0010} & A_{0011} \otimes B_{0011} \\ A_{0100} \otimes B_{0100} & A_{0101} \otimes B_{0101} & A_{0110} \otimes B_{0110} & A_{0111} \otimes B_{0111} \\ A_{1000} \otimes B_{1000} & A_{1001} \otimes B_{1001} & A_{1010} \otimes B_{1010} & A_{1011} \otimes B_{1011} \\ A_{1100} \otimes B_{1100} & A_{1101} \otimes B_{1101} & A_{1110} \otimes B_{1110} & A_{1111} \otimes B_{1111} \end{bmatrix}, \]

\[ \rho_{11} = \frac{1}{N_1} \begin{bmatrix} A_{0000} \otimes B_{1111} & A_{0001} \otimes B_{1110} & A_{0010} \otimes B_{1101} & A_{0011} \otimes B_{1100} \\ A_{0100} \otimes B_{0111} & A_{0101} \otimes B_{0110} & A_{0110} \otimes B_{0101} & A_{0111} \otimes B_{0100} \\ A_{1000} \otimes B_{1011} & A_{1001} \otimes B_{1010} & A_{1010} \otimes B_{1001} & A_{1011} \otimes B_{1000} \\ A_{1100} \otimes B_{0011} & A_{1101} \otimes B_{0010} & A_{1110} \otimes B_{0001} & A_{1111} \otimes B_{0000} \end{bmatrix}, \] (A.8)

where

\[ N_0 = \sum_{j,k=0}^{1} \|A_{j,k,j,k}\| \cdot \|B_{j,k,j,k}\|, \quad (A.9) \]

and

\[ N_1 = \sum_{j,k=0}^{1} \|A_{j,k,j,k}\| \cdot \|B_{j,k,j,k}\|, \quad (A.10) \]
