Abstract

**Background and Aims:** Vitamins are bioactive compounds naturally found in many different types of food and required by the human body for many biological functions and enzymatic activities. Due to their antioxidant properties, certain vitamin derivatives have been synthesized for inclusion in many cosmetics, thus leading to an increasing incidence of allergic contact dermatitis (ACD) cases. Therefore, the present review may be helpful to provide an insight into the sensitizing role of at least certain vitamins and may also offer possible patch test alternatives for definitive diagnosis.

**Methods:** This study was conducted in accordance with the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) guidelines. Literature search regarding ACD cases to vitamins was performed using the Medline, PubMed, Scopus, EMBASE, and Google Scholar databases from January 1940 up to June 2021.

**Results:** A total of 4494 articles matched the keywords used for the researched. Records removed before screening included 15 duplicate articles and 3429 not eligible articles (e.g., not written in English, studies on animals, not relevant to the topic). A total of 1050 articles underwent the screening phase and 258 were therefore excluded as they were not primary studies. Subsequently, 792 articles were considered eligible for the review and 688 of them were finally excluded as they did not report the outcome of interest. Therefore, 104 articles were definitely included in the present review.

**Conclusion:** ACD to vitamins is still probably an underestimated issue in cosmetology, as many vitamins are considered “natural” and therefore “safe” ingredients. On the contrary, according to current literature, almost all vitamins contained in topical products are able to induce allergic reactions, with the exception of vitamin B2 and vitamin B9. Patch tests are not standardized, thus leading to difficulties in diagnosis.

**Keywords**
allergic contact dermatitis, fat-soluble vitamins, hydro-soluble vitamins, lymphocyte transformation test, multivitamins, patch test
1 | INTRODUCTION

Vitamins are organic compounds that are essential for numerous human metabolic functions in many cellular, enzymatic, and biological pathways. However, the human body cannot produce, or else produces very little of most of them so a rich, highly differentiated diet is fundamental for their correct intake. Some vitamins occur naturally in food and each vitamin has been identified and industrially produced, both for pharmaceutical purposes and food supplementation, although commercial vitamins are not completely identical to their natural forms. Synthetic vitamins offer many advantages compared to natural ones, as they can be administered not only orally but also intramuscularly or intravenously. Furthermore, synthetic vitamins can be stored for longer periods, and are not influenced by food deterioration.

Vitamin derivatives are currently available in cosmetics and in food excipients. Vitamins A, E, B3, B5, B6, and C and their derivatives are used for their antioxidant and antiaging properties in cosmetology but also as excipients, preservatives or dyes in food, juices, and drinks. Due to their widespread use, allergic contact dermatitis (ACD) to vitamins is rapidly increasing. However, unlike hydro insoluble vitamins (B1–B9, B12, and C), which are more likely to induce immediate-type reactions, ACD is more frequently induced by fat soluble vitamins (A, D, E, and K). Occupational ACD from vitamins is rarely reported, as also ACD caused by topical use of cosmetics containing vitamin derivatives or their pure forms.

Besides ACD, vitamins can cause contact urticaria, anaphylaxis, photoallergic reactions, erythema multiforme-like eruptions, airborne contact dermatitis, and atopic dermatitis-like lesions. Moreover, vitamins can be responsible for diffuse ACD together with local flare-up after systemic intake and systemic allergy. The latter imposes a burden on these patients since vitamins are contained in food supplements and tablets.

The beneficial properties, recommended amounts, and food sources of the essential vitamins are reported in Table 1, while all denominations and chemical structures are listed in Table 2.

The aim of this review is to update the role of vitamins as inducers of ACD, focusing on clinical manifestations and possible cross-reactivity among them.

2 | METHODS

This study was conducted in accordance with the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) guidelines. Literature search was performed using the Medline, PubMed, Scopus, EMBASE, and Google Scholar databases from January 1940 up to June 2021, inserting the following search terms: allergic contact dermatitis; contact hypersensitivity; photoallergic contact dermatitis; photoallergic contact dermatitis; patch test; photopatch test; fat-soluble vitamins; hydro-soluble vitamins; multivitamins; vitamins; vitamin B complex; vitamin a; vitamin b; vitamin c; allergy; hypersensitivity

2.1 | Inclusion criteria

- Original articles, clinical trials, case reports, review articles, posters, and editorial letters were included.
- Only articles written in English were included.
- Only articles relevant to the main topic were included.
- Only articles regarding primary studies on humans were included.

2.2 | Exclusion criteria

- Articles written in another language different from English were excluded.
- Articles not relevant to the main topic were excluded.
- Articles regarding laboratory studies or studies on animals were excluded.

2.3 | Data quality assessment and management

Title and abstract were used to screen all articles. Relevant abstracts and articles without abstracts were selected for subsequent review. Data on first author, country of origin, publication year, study design, number of cases, age, sex, source of exposure, epicutaneous reaction, patch test materials, and reaction to vitamins were extracted. MS Excel version 2019 (build 14430.20298) was used for statistical analyses.

2.4 | Results

A total of 4494 articles matched the keywords used for the researched. Records removed before screening included 15 duplicate articles and 3429 not eligible articles (e.g., not written in English, studies on animals, not relevant to the topic). A total of 1050 articles underwent the screening phase and 258 were therefore excluded as they were not primary studies. Subsequently, 792 articles were considered eligible for the review and 688 of them were finally excluded as they did not report the outcome of interest. Therefore, only 104 articles were definitely included in the present review (Figure 1).

3 | REVIEW

Literature data on ACD to vitamins, with detailed descriptions of patch testing (tested substances, vehicles, and concentrations) and clinical manifestations, are reported in Table 3.
| Vitamins   | Benefits                                                                                                                                                                                                 | Recommended amount (daily RDA or daily AI) | Food sources                                                                 |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------|-----------------------------------------------------------------------------|
| Vitamin A  | Essential for sight. Lycopene may lower prostate cancer risk. Keeps tissues and skin healthy. Plays an important role in bone growth and the immune system. Diets rich in the carotenoids alpha carotene and lycopene seem to lower lung cancer risk. Carotenoids act as antioxidants. Foods rich in the carotenoids lutein and zeaxanthin may protect against cataract | M: 900 µg (3000 IU) F: 700 µg (2333 IU) | Sources of retinoids: beef liver, eggs, shrimp, fish, fortified milk, butter, cheddar cheese, Swiss cheese Sources of β-carotene: sweet potatoes, carrots, pumpkins, squash, spinach, mangos, turnip greens |
| Vitamin B1 | Helps convert food into energy. Needed for healthy skin, hair, muscles, and brain and critical for nerve function                                                                                      | M: 1.2 mg F: 1.1 mg                           | Pork chops, brown rice, ham, soymilk, watermelons, acorn squash             |
| Vitamin B3 | Helps convert food into energy. Essential for healthy skin, blood cells, brain, and nervous system                                                                                                       | M: 16 mg F: 14 mg                             | Meat, poultry, fish, fortified and whole grains, mushrooms, potatoes, peanut butter |
| Vitamin B5 | Helps convert food into energy. Helps make lipids (fats), neurotransmitters, steroid hormones, and hemoglobin                                                                                           | M: 5 mg F: 5 mg                               | Wide variety of nutritious foods, including chicken, egg yolk, whole grains, broccoli, mushrooms, avocados, tomato products |
| Vitamin B6 | Aids in lowering homocysteine levels and may reduce the risk of heart disease. Helps convert tryptophan to niacin and serotonin, a neurotransmitter that plays key roles in sleep, appetite, and mood. Helps make red blood cells. Influences cognitive abilities and immune function | 31–50 years old: M: 1.3 mg; F: 1.3 mg 51+ years old: M: 1.7 mg; F: 1.5 mg | Meat, fish, poultry, legumes, tofu and other soy products, potatoes, noncitrus fruits such as bananas and watermelons |
| Vitamin B12| Aids in lowering homocysteine levels and may lower the risk of heart disease. Assists in making new cells and breaking down some fatty acids and amino acids. Protects nerve cells and encourages their normal growth. Helps make red blood cells and DNA | M: 2.4 µg F: 2.4 µg                          | Meat, poultry, fish, milk, cheese, eggs, fortified cereals, fortified soymilk |
| Vitamin C  | Aliments rich in vitamin C may lower the risk for some cancers, including those of the mouth, esophagus, stomach, and breast. Long-term use of supplemental vitamin C may protect against cataract. Helps make collagen, a connective tissue that knits together wounds and supports blood vessel walls. Helps make the neurotransmitters serotonin and norepinephrine. Acts as an antioxidant, neutralizing unstable molecules that can damage cells. Bolsters the immune system | M: 90 mg F: 75 mg smokers: add 35 mg          | Fruits and fruit juices (especially citrus), potatoes, broccoli, bell peppers, spinach, strawberries, tomatoes, Brussels sprouts |
| Vitamin D  | Helps maintain normal blood levels of calcium and phosphorus, which strengthen bones. Helps form teeth and bones. Supplements can reduce the number of non-spinal fractures | 31–70: 15 µg (600 IU) 71+: 20 µg (800 IU)    | Fortified milk or margarine, fortified cereals, fatty fish                  |
| Vitamin E  | Acts as an antioxidant, neutralizing unstable molecules that can damage cells. Protects vitamin A and certain lipids from damage. Diets rich in vitamin E may help prevent Alzheimer’s disease | M: 15 mg F: 15 mg (15 mg equals about 22 IU from natural sources of vitamin E and 33 IU from synthetic vitamin E) | Wide variety of foods, including vegetable oils, salad dressings, and margarines made with vegetable oils, wheat germ, leafy green vegetables, whole grains, nuts |
| Vitamin K  | Activates proteins and calcium essential to blood clotting. May help prevent hip fractures                                                                                                              | M: 120 µg F: 90 µg                           | Cabbage, liver, eggs, milk, spinach, broccoli, sprouts, kale, collards, and other green vegetables |
| Vitamin | Name, chemical formula, and chemical structure of vitamins |
|---------|----------------------------------------------------------|
| Vitamin B1 | **Thiamine/thiamin/vitamin B1**<br>Thiamine pyrophosphate (TPP/co-carboxylase), thiamine hydrochloride (TH-HC), thiamine mononitrate (TH-MN) |
| | C$_{12}$H$_{17}$N$_4$OS<br>Aminopyrimidine ring linked to a thiazolium ring by a methylene bridge; methyl and hydroxyethyl side chains are present instead of a thiazole |
| | Vitamin B3/vitamin PP/Niacin/Nicotinic acid<br>Niacinamide/amide nicotinamide |
| | C$_6$H$_5$NO$_2$<br>Derivate of pyridine with a carboxyl group at the 3-position |
| Vitamin B5 | **Vitamin B5/pantotheic acid**<br>Panthenol (pro-vitamin B5); syntetic variants (panthenyl ethyl ether, panthenyl triacetate, calcium and sodium pantothenate) |
| | C$_9$H$_{17}$NO$_5$<br>Combination of pantoic acid and beta-alanine |
| Vitamin B6 | **Vitamin B6/Pyridoxine (PN)**<br>Pyridoxamine (PM), pyridoxal (PL)/pyridoxine hydrochloride |
| | C$_8$H$_{12}$NO$_3$<br>3-Hydroxy-4,5- hydroxymethyl-2-methylpyridine |
| Vitamin B7 | **Vitamin B7/Vitamin H/Biotin** |
| | C$_{10}$H$_{16}$N$_2$O$_3$S<br>Heterocyclic, sulfur-containing, monocarboxylic acid with two rings (imidazolidone and tetrahydrothiophene moieties) fused together |
| Vitamin B12 | **Vitamin B12/Cobalamin**<br>Cyanocobalamin (the most stable; used in pharmaceuticals), hydroxocobalamin, adenosylcobalamin (active), methylcobalamin (active) |
| | C$_{63}$H$_{88}$CON$_{14}$O$_{14}$P<br>Planar group containing a corrin ring cetered by a cobalt ion and a nucleotide set |

| | C$_{20}$H$_{46}$O$_2$<br>Common 2-methyl-1,4 naftoquinone core, called menadione, and a phytol side chain at the 3-position. This side chain, which is an isoprenoid structure, may display different lengths and degrees of saturation depending on the specific isoform |
3.1 | ACD to hydro-soluble vitamins

All hydro-soluble vitamins have been reported to be responsible for ACD, except for vitamin B2 and vitamin B9. Due to their increasing role in cosmetics and as topical therapeutic agents, the incidence of ACD induced by hydro-soluble vitamins seems to be rising.

3.1.1 | Vitamin B1

ACD to thiamine has been rarely described, mainly in occupational settings and pharmaceutical industries. Fingers, hands, and wrists are the sites most frequently involved, with a possible further spread to forearms and other body regions. The face (eyelids, periorbital, and perioral regions) may also be involved through airborne contact or self-contamination. Moreover, oral assumption of vitamin B1 or multivitamins containing vitamin B1 may cause systemic allergy.

Patch tests using different thiamine epitopes showed that the whole molecule is highly immunogenic, with a possible cross-reactivity between thiamine and thiamine pyrophosphate (TPP or co-carboxylase). Oral challenge test may be required in uncertain cases.

3.1.2 | Vitamin B3

ACD has been reported more frequently following the topical use of nicotinic acid esters than of pure niacin or niacinamide. Besides classical eczematous lesions on the site of application, a case of allergic contact mucositis to a toothpaste with benzyl nicotinate and propyl nicotinate, presenting as a burning mouth syndrome, was also described.

Patch tests to nicotinic acid and its esters are not yet fully standardized, and probably the pyridine ring is the true immunogenic site. Therefore, since a pyridine ring is present in the chemical structure of various drugs, such as isoniazid, cross-sensitization may be expected. However, Sasseville et al. demonstrated that cross-reactivity among different pyridine derivatives and nicotinic acid is rare. The pyridine ring is also contained in the basic structure of vitamin B6, but no cross-reactivity between the two vitamins has been reported.

3.1.3 | Vitamin B5

Vitamin B5 and its derivatives, widely used in pharmaceutical and cosmetic compounds, such as hair and skin conditioning agents,
| Name                          | Cases | Vehicle and concentrations | Peculiar clinical manifestations |
|-------------------------------|-------|-----------------------------|----------------------------------|
| Vitamin B1 Thiamine          | 3     | Pure thiamine (20,32)<sup>a</sup> |                                  |
|                               | 1     | 0.1% aq (32)                |                                  |
|                               | 2     | 1% aq (19, 32)              |                                  |
|                               | 1     | 5% aq (19)                  |                                  |

have been reported as causative agents of ACD ranging from classic localized eczematous lesions at the site of contact\textsuperscript{36} to generalized eczematous eruptions.\textsuperscript{31,37} Interestingly, a single case of contact urticaria induced by dexpathenol has been reported,\textsuperscript{10} as well as an exacerbation of a pre‐existent ACD to dexpanthenol after the systemic ingestion of pantothenic acid.\textsuperscript{27} Moreover, an increased risk for anaphylaxis has been documented following multivitamin intake in patients sensitized to dexpanthenol through routine contact with dairy products.\textsuperscript{12}

Dexpanthenol contained in hair lotions and conditioners,\textsuperscript{36} sunscreens,\textsuperscript{8,9,24–40} facial moisturizing preparations,\textsuperscript{41,42} make‐up‐remover wipes,\textsuperscript{43} and cream applied after a permanent tattoo\textsuperscript{44} has been reported as responsible for ACD. Leg ulcers and stasis dermatitis have been identified as the main risk factors for ACD to dexpanthenol.\textsuperscript{45}

To date, there is no standardization regarding the best concentrations and vehicles for patch testing dexpanthenol,\textsuperscript{46,47} considered a strong sensitizer that does not cross‐react with D‐panthenyl ethyl ether.\textsuperscript{46–48}

Vitamin B5 in cosmetics as calcium pantothenate was reported to be a relevant sensitizer.\textsuperscript{59} However, due to the complexity of vitamin B5 metabolic pathways, it is also possible that pantothenate may require metabolic activation. Metabolic pathways activated by microsomes play an important role in biochemical modifications of the hapten.\textsuperscript{50} Even if some authors identified the beta‐alanine group as the antigenic determinant of pantothenic acid,\textsuperscript{75,36} biochemical studies have demonstrated that the whole molecule displays immunogenic properties.\textsuperscript{51}

3.1.6 | Vitamin B12

Vitamin B12, also known as cobalamin, is one of the few organo‐metallic compounds occurring in nature, identified in 1948 as the last hydro‐soluble vitamin. Its peculiar biochemical structure mainly includes a carbon‐metal bond and a cobalt atom in its core corrin ring.\textsuperscript{57} The biologically active forms of vitamin B12 found in nature are adenosyl cobalamin and methylcobalamin, while cyanocobalamin is the most stable synthetic form, frequently used for pharmaceutical
deficiency of these, and their consumption is lower. On the other hand, fat-soluble vitamins does not seem to induce local flare due to their high lipophilia. However, the ingestion of fat-soluble vitamins can be partially produced by the body, thus inducing a certain level of immune tolerance. Finally, fat-soluble vitamins can be absorbed only during a caloric fatty meal, an aspect which should always be taken into account when performing an oral challenge test with these vitamins.

3.2 | Lipid-soluble vitamins

Fat-soluble vitamins seem to be more sensitizing than hydro-soluble ones due to their high lipophila. However, the ingestion of fat-soluble vitamins does not seem to induce local flare-up of ACD, as observed with hydro-soluble vitamins. Humans have a three-months’ storage of fat-soluble vitamins, and so suffer less frequently from a deficiency of these, and their consumption is lower. On the other hand, fat-soluble vitamins are more likely to cause vitamin intoxication. For these reasons, their concentration in multivitamin supplements is low. Furthermore, fat-soluble vitamins can be partially produced by the body, thus inducing a certain level of immune tolerance. Finally, fat-soluble vitamins can be absorbed only during a caloric fatty meal, an aspect which should always be taken into account when performing an oral challenge test with these vitamins.

3.2.1 | Vitamin A

Due to their beneficial properties as antioxidant agents and to their role in reversing solar skin damage, vitamin A derivatives have been added to cosmetics. However, besides their cosmetic use, vitamin A esters, and above all beta-carotene, are also approved as food colorants by both the European Authorities and the FDA. The first case of ACD elicited by topical all-trans-retinoic acid (TRA), and confirmed by leukocyte migration inhibition test, was reported by Jordan et al. in 1975. Interestingly, since patch testing was positive for retinoid acid (at different concentrations and in different vehicles) and negative for retinol, retinal, and retinol palmitate, the terminal polar carbon-oxygen functional group of retinoic acid was considered to be the allergen, without cross-reactivity with other vitamin A derivatives.

Due to its use in cosmetics and topical treatments, tretinoin has been related to many cases of ACD, mainly involving the facial area in young patients. Patch testing with tretinoin is not always easy to perform; ethyl alcohol is probably a suitable vehicle. Avoidance of oral administration of isotretinoin after contact sensitization to tretinoin has been suggested, due to the possible cross-sensitivity.

Topical retinol palmitate was related to some cases of ACD, also in combination with tocopheryl acetate (vitamin E). Moreover, a single case of occupational ACD to retinyl acetate with relapsing airborne eczematous lesions was reported, confirmed by positive patch tests with retinyl acetate at different concentrations (0.1%, 0.5%, 1%, 5%, and 10% in pet). Tazarotene and less frequently adapalene are common irritant agents, but are generally considered to be very rare sensitizers. In fact, only a single case of ACD to a topical product containing both adapalene and benzoyl peroxide was described. However, systemic retinoids have been reported to facilitate the development of ACD to other topical products due to their skin barrier-damaging properties.

3.2.2 | Vitamin D

Vitamin D analogs have been successfully used to treat secondary hyperparathyroidism in patients with chronic kidney disease, while other synthetic derivatives (calcipotriol, calcitrol, and maxacalcitol) are widely used as topical therapeutics for psoriasis, with possible ACD. Calcipotriol seems to be more likely to induce ACD than calcitrol or maxacalcitol, probably due to its wider marketing. Moreover, no cross-sensitivity between calcipotriol and calcitriol has been demonstrated.
3.2.3 | Vitamin E

Alpha-tocopherol occurs in nature as a single stereoisomer, while synthetic vitamin E is usually a mixture of eight stereochemical isomers. Therefore, chemically synthesized alpha-tocopherol is not identical to its natural form.4,86

Due to its poor water solubility, new esters of alpha-tocopherol have been synthesized to increase their water dispersion, as well as their stability and shelf-life.4,87 Besides their role as dietary supplements, vitamin E esters are largely used also as antioxidant and antiaging agents in cosmetics.5

The first case of ACD to vitamin E was reported in 1965 by Brodkin et al.88 in a patient with an earlobe dermatitis after the local application of a cream containing vitamin E.89 Since then, several cases of ACD to vitamin E have been described, contained in deodorants,90,99 body oils,91,92 hair lotions,93 and moisturizers.78,94 Vitamin E was the third most common contact allergen present in 151 of 276 samples of moisturizers (55%), after fragrances (68%) and parabens (62%).95 D,L-alpha-tocopherol (synthetic origin) induces dermatitis more frequently than D-alpha-tocopherol (natural origin). Moreover, the higher the concentration of vitamin E in its pure oils, the greater the risk of them causing ACD.96

ACD to vitamin E exhibits two main clinical patterns: an eczematous dermatitis involving the face and/or the extremities, and a generalized eruption spreading from the site of vitamin E originated from incorrect storage. For these reasons, correct storage of vitamin E esters is important to avoid the development of eczematous lesions on hands, face, neck, and temperature, easily undergoing oxidation and thus releasing different degradation products, such as alpha-tocopheryl quinine and tocopheryl acetate.102–104 In two cases of sensitization to VEA® lipogel, a cosmetic formulation containing tocopherol acetate, the culprit agent was a tocopherol acetate oxide product that presumably originated from incorrect storage. For these reasons, correct storage of vitamin E-based cosmetics is important to avoid the development of degradation products, thus suggesting that patch testing or ROAT should be performed with patients’ products only if optimally stored.104 Furthermore, tocopherol seems to be a stronger sensitizer than tocopherol, and probably acts as an adjuvant, since contact allergy to vitamin E is often associated to other sensitizations such as to vitamin A.78,80 glycyrhetic acid,100 decyl oleate,98 and Aloe vera.105 The vitamin E esterification seems to influence its immunogenic properties, since cross-reactivity among different esters was not elicited by patch testing.93,94,97,106 Given its increasing use in cosmetics and topical products, it has been suggested that vitamin E should be included in routine patch test series.96,97 although the optimal concentration and vehicle are not known. Currently, there is no evidence that dietary vitamin E intake may induce a flare-up of skin lesions in topically sensitized patients, although some authors recommend these patients to avoid vitamin E intake.11,90

3.2.4 | Vitamin K

Vitamin K occurs naturally in two forms, vitamin K1 and vitamin K2, while vitamins K3–K7 are synthetic. Vitamin K1, also known as phyloquinone or phytodinitone, can be generally found in plants, while vitamin K2 is synthesized by Gram-positive bacteria in the human large intestine.107 Although synthetic versions of vitamins K1, K3, K4, and K5 have been used in clinical practice, vitamin K1 is the predominant dietary form, and also the most widely used preparation for both intravenous and oral administration.

The first description of an ACD induced by the topical application of vitamin K1 dates back to 1942.108 Two sources of sensitization have been identified: cosmetic products and occupational exposure. Since vitamin K1 is contained in many different cosmetics such as creams against either hyperpigmentation or rosacea, ACD to vitamin K1 generally manifests with eczematous lesions and localized edema mainly involving the periorbital area and the eyelids.109–113 For these reasons, in November 2009, vitamin K1 use in cosmetics and other topical formulations was forbidden in Europe.114 Vitamin K1 was then replaced by its oxide, 2,3-epoxy phytylmenaquinone, even if cases of ACD to vitamin K1 oxide have also been reported. Although vitamin K1 oxide seems to display a weaker sensitizing action compared to vitamin K1 itself, Garcia-Gavin et al. reported three patients who developed ACD due to the use of a cream containing vitamin K1.114–116 Moreover, a high cross-reactivity between vitamin K1 and its oxide has been reported, as ACD can be provoked by its oxide in patients previously sensitized to vitamin K1.115,116 For these reasons, since vitamin K1 oxide is not provided by manufacturers, vitamin K1 as is can be used for patch testing.10 Vitamin K1 may also cause erythema multiforme-like contact dermatitis17 and photoallergic reactions.16

Occupational sensitization is mainly to vitamin K3 sodium bisulfite, affecting patients working in both veterinary and pharmaceutical industries.117–119 Vitamin K3 sodium bisulfite may lead to the development of eczematous lesions on hands, face, neck, and eyelids, sometimes associated with gastrointestinal symptoms.119 However, since vitamin K3 sodium bisulfite is a well-known irritant compound, serial dilutions (0.01% and 0.1% in aq.) have been suggested117–120

Even if a case of cross-sensitiveness between sodium bisulfite and vitamin K4 was reported,117 sodium bisulfite 5% in aq. resulted negative and without cross-reactivity with vitamin K1.120

4 | RESULTS

ACD to vitamins is still probably an underestimated issue in cosmetology, as many vitamins are considered “natural” and therefore “safe” ingredients. On the contrary, according to current
literature, almost all vitamins contained in topical products are able to induce allergic reactions, with the exception of vitamin B2 and vitamin B9.

From the careful review of literature and considering the fragmentation of collected data, mainly based on single case reports extrapolated from literature, it is evident that the ACD to vitamins are induced by synthetic forms of vitamins, whose formulations allow their use as topical products.

Previously, indeed, the onset of an ACD to vitamins involved subjects working in the pharmaceutical industry and occupationally exposed to vitamins or their intermediates originated from the process of synthetic production. Moreover, it has been suggested that water-soluble vitamins are more likely to induce immediate type reactions like urticaria or anaphylaxis whereas lipid-soluble vitamins are more prone to cause ACD for their own greater lipophilia, above all, when used in cosmetics or moisturizers. The example of ACD to vitamin E in USA is paradigmatic, given its wide use in topical products and the consequent high incidence of alpha tocopherol-induced ACD in that country. However, the increased cosmetic use of water-soluble vitamins such as vitamin B5, or vitamin C derivatives is quickly gaining the gap in inducing ACD by such a group of vitamins and some clinicians have focused their attention on such substances, suggesting to include them in patch tests series for cosmetics or to perform investigations on larger cohorts of patients with ACD. The drugs originated from vitamins represent another riddle, for the potential allergic cross-reaction between the synthetic drug-derivative and the naïve vitamin. Such an occurrence has been poorly investigated, as in the cases of vitamin A and D only. Yet, it is interesting to evidence the possibility of a dermatitis flare-up following the ingestion of the culprit vitamin, above all as assumed in a multivitamin preparation, that is always a synthetic vitamin form but may involve even vitamins naturally present in foodstuff, leading patients to follow a low-content diet for the responsible vitamin, although that circumstance seems to occur exceptionally. Lastly, the review of literature has evidenced the scarce and not yet optimal standardization of vitamins patch tests, as illustrated in Table 2, while cutaneous tests are the gold standard to diagnose an ACD.

5 | CONCLUSION

The increasing use of vitamins in cosmetics and daily consumer products is responsible for rising rates of ACD in the general population. Even if ACD to vitamins is not frequent, the etiologic diagnosis is mandatory to establish correct prevention measures, and in this setting patch testing is the gold standard. Nevertheless, diagnosis is not always easy due to the absence of standardization in patch testing, as also in other in vivo methods.

ACD from vitamins is an issue for dermatologists, considering that sensitization from cosmetics or other skin products containing vitamins may induce systemic reactions when vitamins are orally administered in apparently innocent multivitamin dietary supplements. In fact, semisynthetic vitamins are administered orally and parenterally for therapeutic purposes and are increasingly marketed: it has been estimated that more than 90,000 dietary supplementation products containing vitamins and minerals are available on the USA market. Nowadays, almost 52% of the adult USA population regularly take vitamins and multivitamins, whereas in Europe and Latin America vitamin intake is less common and the lowest percentage (13%-17%) is registered in France, Italy, and Spain probably due to the more balanced diet.
