State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing 100193, China

ABSTRACT

Plant extracts have been proved as natural antioxidants resources as well as alternative feed additives in livestock and poultry species. Chestnut wood extract (CWE) as a source of hydrolysable tannic acid was used to evaluate the growth performance, nutrient retention, meat quality, antioxidant status, and immune function of broilers. A total of 168, day-old Arbor Acre male broilers (weight 46.59 ± 0.44 g) were randomly divided to 3 treatments, 7 replicate pens per treatment, 8 broilers per pen. The treatments contain a control diet, CON (corn-soybean meal basal diet); an antibiotic diet, CTC (basal diet + 75 mg/kg chlortetracycline); and chestnut wood extract diet, CWE (basal diet + 1,000 mg/kg chestnut tannins). At the finisher phase, final body weight was higher (P < 0.05) in CWE supplemented diet than in CON. Average daily body weight gain was higher (P < 0.05) and feed gain ratio was lower (P < 0.05) in broilers fed CWE than in those fed CON at the finisher phase. Crude protein digestibility was higher (P < 0.05) in broilers offered CWE than that in broilers fed CON and CTC diets. Breast muscle pH value at 24 h (pH24 h) was higher (P < 0.05) in broilers fed CWE than that in those fed CON and CTC diets. The bursa weight was higher (P < 0.05) in broilers offered CWE than that in those fed CON and CTC. Total antioxidant capacity (T-AOC), glutathione peroxidase (GSH-Px), and superoxide dismutase (SOD) values were higher (P < 0.05) in both breast muscle and thigh muscle of broilers offered CWE supplemented diet than those in broilers fed CON and CTC diets. Similarly, broilers offered with CWE diets showed higher (P < 0.05) T-AOC, GSH-PX, and SOD value in serum than those fed CON and CTC diets. Serum concentration of IgG was higher (P < 0.05) in broilers offered with CWE diets than that in those fed CON and CTC diets. Total cholesterol, low-density lipoprotein cholesterol, and urea-N concentration were lower (P < 0.05) in broilers offered CWE diet than those in broilers fed CON and CTC diets. It was recommended to supply CWE at the 1,000 mg/kg level for improving antioxidant status, cholesterol metabolism, and growth performance without affecting normal meat quality in broilers.

Key words: antioxidant status, broiler, cholesterol metabolism, meat quality, chestnut wood extract

INTRODUCTION

Plant extracts have been studied as alternative feed additives and were reported as good source of natural antioxidants to improve animal production and health status (Hu et al., 2017). However, plant extract contains higher amount of polyunsaturated fatty acids that may lead to oxidative stress in chickens (Gao et al., 2010). Tannins are secondary plant metabolites that are commonly classified under 2 groups, condensed tannins and hydrolysable tannins. Condensed tannins hold the antinutritional factors and could decrease protein digestibility because of its protein precipitation nature, and thus, the long-term uses of condensed tannins could decrease the growth performance and nutrient digestibility in monogastric animals (Smulikowska et al., 2001; Liu et al., 2020). On the other hand, it is believed that hydrolysable tannic acid is made from wood extract that has higher polyphenolic compounds (Kumar and Vaithiyanathan, 1990; Liu et al., 2018). Supplementation of tannins could improve the body weight gain in rabbits (Liu et al., 2012) and broilers (Dong et al., 2015; Xiong et al., 2016). However, Jamroz et al. (2009) found that supplementation of 250 or 500 mg/kg chestnut tannins had no significant...
effects on body weight gain and feed-to-gain ratio, whereas 1,000 mg/kg diets reduced the final body weight in broilers. Furthermore, chestnut tannins could improve intestinal morphology, cytokine expression, and antioxidative activities in broilers (Liu et al., 2018). Dietary supplementation of chestnut wood extract (CWE) as hydrolysable tannins could reduce carcass fat deposition and water-holding capacity of meat and increase polyunsaturated fatty acids in fat tissues of pigs (Rezar et al., 2017). Moreover, hydrolysable tannic acid is commonly used in monogastric animals as a natural source of antioxidants (Biagi et al., 2010; Starčević et al., 2015). Dietary supplementation of antioxidant can play a great role in improving the health status in poultry. Oxidative stress is defined as the rise in reactive oxygen species level, which could reduce the live weight gain via altering normal metabolism and cause poor meat quality by increasing plasma corticosterone level which is associated with paler breast meat in broilers (Kannan et al., 1997). In addition, oxidative stress induces biological damage to DNA, proteins, and lipids and is responsible for several health problems that affect growth performance and productivity of livestock (Xing et al., 2019). In a recent study, Ebrahim et al. (2015) reported that hydrolysable tannic acid is effective in attenuating oxidative stress in broilers. In addition, Schiavone et al. (2008) noted that feed ingredients rich in tannins can be used as a substitute of antibiotics in poultry. Voljč et al. (2013) also reported that sweet CWE could reduce DNA damage and plasma malondialdehyde (MDA) in broilers with a combination of α-tocopherol.

On the other hand, antibiotic has been used for few years with a view to enhance growth performance and health status in broilers (Mahfuz et al., 2019). But over-application of antibiotics in food animal production has created health hazards (Mahfuz et al., 2018a). Currently, the European Union, the United States, and other developed countries have prohibited the application of in-feed antibiotics (Li et al., 2019; Long et al., 2019). Thus, searching an alternative for in-feed antibiotics in poultry is given higher attention by the poultry researchers (He et al., 2019). A great deal of research on poultry nutrition focused on the utilization of different feed grains rich in tannins, but little work has been carried out using purified tannin as feed additives till now.

Therefore, the current experiment was conducted to examine the hypotheses that dietary CWE as a source of hydrolysable tannic acid can replace in-feed antibiotic and improve the growth performance, nutrient digestibility, meat quality, antioxidant status, immune function, and lipid metabolism in broilers.

**MATERIALS AND METHODS**

**Experimental Design and Diets**

The research was conducted at a broiler experimental unit, China Agricultural University, and approved by Animal Care and Use Committee of China Agricultural University (Beijing, China; no. CAU-XSPLAB-B-2019-02). The CWE as a source of hydrolysable tannic acid was provided by the Gruppo Mauro Silvachimica Srl (Cuneo, Italy), which contained ≥75% tannin, crude fiber <2.00%, ash <2.50%, and moisture <8.00%. Tannin percent was measured by gravimetric analysis of vegetable tannin agents and extracts by using the filter Frei-berg hide powder method (Kuntzel, 1954). A total of 168, day-old Arbor Acre male broilers (weight 46.59 ± 0.44 g) were randomly divided to 3 treatments, 7 replicate pens per treatment, 8 broilers per pen. All broilers were kept in an environment-controlled room. Brooding house temperature was 34°C, and it was decreased by 3°C for per week until it reached 23°C and then remained constant. The treatments contain a control diet, CON (corn-soybean meal basal diet); an antibiotic diet, CTC (basal diet + 75 mg/kg chlortetracycline); and chestnut wood extract diet, CWE (basal diet + 1,000 mg/kg chestnut tannins). Two different types of diets (starter diet for 0–21 D; finisher diet for 22–42 D) were considered to meet the nutrient levels followed by National Research Council (National Research Council, 1994) specification (Table 1). CWE and antibiotic were mixed with premix first and then mixed thoroughly with each basal diet via feed millers.

**Growth Performance and Nutrient Retention**

On day 21 and 42, followed by fasting for 12 h, broilers were weighed to calculate average daily weight gain, feed intake, and feed conversion ratio. Fecal samples were collected from day 40 to 42 in each pen, dried in an oven (65°C) for 72 h, and used to prepare the subsample. Diets and fecal subsamples were analyzed for dry matter, organic matter, crude protein, and ether extract (EE) according to the methods of AOAC (2004). Chromium content (2 g/kg) that was used as a marker was analyzed using an atomic absorption spectrophotometer (Z-5000 Automatic Absorption Spectrophotometer; Hitachi, Tokyo, Japan) according to Williams et al. (1962). Gross energy was determined via an automatic isoperibolic oxygen bomb calorimeter (Parr 1281, Automatic Energy Analyzer; Parr Instrument Company, Moline, IL). OM was calculated using the following formula:

$$\text{OM} = 1 - \text{ash content (DM} - \text{base).}$$

**Meat Quality and Viscera Weight**

On the morning of day 42, one bird per replicate (n = 7) close to the average body weight was slaughtered by cervical dislocation; viscera (liver, spleen, thymus, and bursa), breast muscle, and thigh muscle were collected; and then viscera percentage was calculated.

The pH values at 45 min and 24 h postmortem of meat sample (breast muscle) were measured at 3 locations via portable pH meter (pH-star; Thermo Fisher, Matthaus,
Germany). Duplicate measurement of sample was performed, and the average values were considered as the final values. Drip loss was measured according to Cheng et al. (2019). Briefly, the samples were trimmed and weighed and then placed in an inflated plastic bag and hung for 24 h at 4°C. After 24 h, the samples were weighed again. Drip loss was calculated as a percentage based on weight before and after hanging. The color value of breast muscle and thigh muscle was estimated in duplicates using a chromameter (CR-410; Konica Minolta, Tokyo, Japan). The test units L*, a*, and b* indicated the lightness, redness, and the yellowness of meat, respectively.

### Analysis of Antioxidant Parameters

On day 42, blood samples were obtained from jugular vein of euthanized birds (n = 7). Serum was prepared by centrifuging at 3,000 × g for 20 min at 4°C and was preserved at −80°C for analysis. Concentration of total antioxidant capacity (T-AOC), superoxide dismutase (SOD), glutathione peroxidase (GSH-Px), and MDA in serum, thigh muscle, and breast muscle were determined by using an automatic biochemical analyzer (RA-1000; Bayar Corp., Tarrytown, NY) using colorimetric methods following the instructions of commercial assay kits (Zhongsheng Biochemical Co., Ltd., Beijing, China).

### Analysis of Serum Immune and Lipid Indices

The serum IgA, IgG, IgM, IL-6, IL-1β, and tumor necrotic factor-α (TNF-α) were measured using ELISA Kits (Shanghai Junshi Biosciences Co. Ltd., Shanghai, China), and value was measured at 450 nm. The concentrations of total cholesterol (TC), triglyceride, high-density lipoprotein (HDL) cholesterol, and low-density lipoprotein (LDL) cholesterol in serum sample were measured using commercial kits (Zhongsheng Biochemical Co. Ltd., Beijing, China) via an automatic biochemical analyzer (RA-1000; Bayer Corp., Tarrytown, NY).

### Statistical Analysis

One-way ANOVA was applied via SPSS (2006). The pen was the experimental unit. The effects of treatment were partitioned into the main effects of CTC and CWE. Duncan’s multiple range test was applied to separate the statistical differences. Mean value and SEM were used to express results. P < 0.05 is considered significant.
RESULTS

Growth Performance of Broilers

Compared with control (CON), final body weight (finisher phase) was higher \((P < 0.05)\) in CWE-supplemented diet. At the finisher phase, average daily body weight gain was higher \((P < 0.05)\) and feed gain ratio was lower \((P < 0.05)\) in broilers fed CWE than those in broilers fed CON. However, no differences were found when compared with antibiotic (CTC) diet. Similarly, no differences were observed for all the performance parameters among the groups at the start and in the overall period (Table 2).

Nutrient Retention

Crude protein digestibility was higher \((P < 0.05)\) in broilers fed CWE than that in those fed CON and CTC diets. No significant differences were observed for dry matter, organic matter, crude protein, gross energy, and EE retention in broilers among the groups (Table 3).

Meat Quality and Viscera Organ Weight

The breast muscle pH value at 24 h (pH24h) postmortem was higher \((P < 0.05)\) in broilers fed CWE than that in those fed CON and CTC diets, while there were no significant differences for other parameters of meat quality including drip loss percent and meat color (Table 4).

The bursa weight was higher \((P < 0.05)\) in broilers offered CWE than that in those fed CON and CTC, whereas no significant differences \((P > 0.05)\) were noted for other inner relative organ (liver, spleen, thymus) weight (Table 5).

Antioxidant Status in Muscle Tissue and Serum

In breast muscle, T-AOC, GSH-PX, and SOD values were higher \((P < 0.05)\) in broilers offered CWE-supplemented diet than those in broilers fed CON and CTC diets (Table 6). Similarly in thigh muscle, T-AOC, GSH-PX, and SOD values were higher \((P < 0.05)\) in broilers offered CWE-supplemented diet than those in broilers fed CON and CTC diets. However, no significant differences were noted for MDA value among the treatments of both samples.

Broilers offered with CWE diets showed higher \((P < 0.05)\) T-AOC, GSH-PX, and SOD values in serum than those fed CON and CTC diets (Table 6). MDA value was not affected by CWE supplementation.

Immune Status in Serum

Serum concentration of IgG was higher \((P < 0.05)\) in broilers offered with CWE diets than that in those fed CON and CTC diets (Table 7). No significant differences were noted for the other value of measured immune subparameters (IgA, IgM, IL-6, IL-1β, TNF-α) among the treatments in the serum sample of experimental broilers.

Metabolic Indices in Serum

TC and LDL concentration were lower \((P < 0.05)\) in broilers offered CWE diet than in those fed CON and CTC diets (Table 8). Urea-N concentration was lower \((P < 0.05)\) in CWE-supplemented diets than that in CON and CTC diets. However, no significant effects were noted for triglyceride and HDL concentration among the treatments in this study.

**DISCUSSION**

In this experiment, the CWE was used as source of hydrolysable tannic acid in broiler diets which contained more than 75% tannins. Our present study did not find any significant differences in broiler performances during the overall experimental period. Similar to the current finding, Jamroz et al. (2009) did not find any significant effects on body weight gain and feed-to-gain ratio in broilers fed chestnut tannins (250 or 500 mg/kg). In addition, Brenes et al. (2008) used grape pomace (condensed tannins about 1,500 mg/kg) at different levels (15 mg, 30 mg, and 60 mg/kg) in broiler diets and did not find any significant difference in body weight gain and feed intake compared with control, which was similar to our present finding. We hypothesized that the supplementation dosages of CWE might be smaller to change the performances parameters during the overall experimental period (day 1–42). In addition, Candek-Potokar et al. (2015) reported that there were no significant effects on average daily gain and gain-to-feed ratio in pigs fed with tannin-supplemented diets. However, we have observed a higher final body weight and daily body weight gain at the finisher period, which was due to the higher crude protein retention in TA-supplemented diets of experimental broilers. Schiavone et al. (2008) reported that the final body weight was higher in experimental broilers offered natural extract of chestnut wood at 0.2% level, which was also similar with our current findings. Similarly, some past studies reported that tannin sources could improve growth performance in pigs and chickens as well (Brus et al., 2013; Starčević et al., 2015).

Higher crude protein digestibility in our trial was similar to the results noted by Brufau et al. (1998) who used heat treatment of faba bean (Vicia faba L) that contains tannin in Leghorn chickens. We hypothesized that CWE as a source of hydrolysable tannins was well absorbed and enhanced digestive enzyme activities in the gastrointestinal tract of experimental broilers that may had a role in improving crude protein digestibility in this study. Molino et al. (2018) observed that chestnut hydrolysable tannins were easily available for microbial fermentation as it has prebiotic activity that may be beneficial for nutrient utilization. However, Schiavone et al. (2008) did not find any significant differences in digestibility of dry matter, EE, and energy in broilers offered chestnut tannins which justified our present findings. Data regarding the effects of hydrolysable tannins on nutrient digestibility in broilers are still scarce. The actual mechanism to increase relative bursa weight in the present trial was not clear. However, we hypothesize that it may be associated with better immunity of birds fed CWE. The bursa is a very important central immune organ, which is an indicator of better health status and good physiological response to body immune system.

\(^1\)Data represented the mean value of 7 sample per treatment.
The higher pH value at 24 h (pH24h) in the breast muscle of broilers fed CWE-supplemented diets might be a good indicator of meat quality because its declining rate is associated to meat tenderness (Lonergan et al., 2011). However, this study did not investigate the role of CWE at different levels of supplementation in immune function in broilers. We also hypothesized that dietary inclusion of CWE up to 1,000 mg/kg does not affect the overall meat quality in broilers, which may probably be the lowest level of supplementation in diets. Similar to our finding, dietary supplementation of sweet chestnut tannins had no effects on meat color in pigs (Rezar et al., 2017).

This study assumed that CWE contains hydrolysable tannic acid that may have had a role in increasing the value of T-AOC, SOD, and GSH-PX in serum, breast muscle, and thigh muscle samples of broilers. A previous study reported that the extracts of chestnut skins had antioxidant properties, particularly against lipid peroxidation (Barreira et al., 2008). In a recent study, Liu et al. (2018) noted that inclusion of 2 g/kg chestnut tannins could increase T-AOC and SOD values in the jejunal mucosa of broilers. On the other hand, Starčević et al. (2015) found higher oxidative susceptibility of the liver and breast muscle in broilers fed tannic acid at the 5 g/kg level. Similarly, Dong et al. (2015) found that broilers fed with polyphenolic extracts as tannins had higher T-AOC, SOD, and GSH-PX values in intestinal epithelial cell line-6. Moreover, Brenes et al. (2008) noted higher antioxidant activities in serum and breast muscle of broilers offered grape pomace (tannins about 1,500 mg/kg) at 60 g/kg. With the contrast of the study by Liu et al. (2009), MDA levels in muscle were lower in rabbits fed chestnut tannins. Voljč et al. (2013) also found lower plasma MDA in broilers fed with sweet chestnut wood and α-tocopherol. The differences of MDA values may be associated with animal species, dosages, and interaction of diets in treatment. Collectively, the significant positive role on antioxidant status in serum and muscle tissue indicated that supplementation of CWE may be used as a potential natural antioxidant in broiler diets.

In the present research, serum IgG was increased in broilers fed with CWE which could be beneficial because of their fast-growing nature and susceptibility to environmental stressors. IgG is a leading antibody for mucosal immunity that can neutralize pathogens via the nonspecific defense system of body. Previous study also showed that immunity was influenced by improving the antioxidant status of broilers (Iqbal et al., 2015). However, this study did not observe any significant differences in proinflammatory cytokines. Liu et al. (2018) reported that IL-6 and TNF-α concentration of jejuna mucosa were decreased in heat-stressed broilers offered chestnut tannins. As the present experiment was conducted in normal condition, the optimum level of proinflammatory cytokines expression was expected. In this study, we have applied only one dosage of CWE; thus, this study could not conclude the firm role of CWE supplementation in immune function in broilers. Therefore, we suggest for further research to investigate the role of CWE at different levels of supplementation in immune function in broilers.

This study also ensured the positive role of CWE in cholesterol metabolism (TC and LDL) in broilers. We hypothesized that CWE may have had a role in reducing the activity of hepatic 3-hydroxy-3-methylglutaryl coenzyme A in experimental broilers. Abdulkarimi et al. (2011) reported that MHG-CoA is the key regulatory enzyme for cholesterol synthesis. Furthermore, additional fiber in chestnut wood may play a role in reducing cholesterol concentration in serum of experimental broilers via improving metabolism. Similar to the current finding, Starčević et al. (2015) found a lower cholesterol concentration in serum of broilers fed tannic acid at 5 g/kg level. In addition, TC and LDL concentration

### Table 7. Effect of dietary chestnut wood extract supplementation on serum immune parameters in broilers.1

| Item     | CON   | CTC   | CWE   | SEM   | P value |
|----------|-------|-------|-------|-------|---------|
| IgA (g/L)| 4.27  | 4.25  | 4.26  | 0.05  | 0.983   |
| IgG (g/L)| 2.28a | 2.20b | 2.38b | 0.03  | 0.033   |
| IgM (g/L)| 1.68a | 1.68  | 1.64  | 0.02  | 0.655   |
| IL-6 (pg/mL)| 125.32 | 133.15 | 128.66 | 1.36 | 0.070   |
| IL-1β (pg/mL)| 27.97 | 26.92 | 24.80 | 1.51 | 0.163   |
| TNF-α (pg/mL)| 47.47 | 51.73 | 47.36 | 1.16 | 0.267   |

SEM, pooled standard error of the means. Different superscript lowercase letters in the same row means significantly different at $P < 0.05$.

Abbreviations: CON, control; CTC, antibiotic (chlortetracycline); CWE, chestnut wood extract; IgA, immunoglobulin A; IgG, immunoglobulin G; IgM, immunoglobulin M; IL-6, interleukin-6; IL-1β, interleukin-1β; TNF-α, tumor necrotic factor-α.

1Data represented the mean value of 7 sample per treatment.

### Table 8. Effect of dietary chestnut wood extract supplementation on serum metabolic indices in broilers.1

| Item    | CON      | CTC      | CWE      | SEM      | P value |
|---------|----------|----------|----------|----------|---------|
| TC (mmol/L) | 1.55a    | 1.60a    | 1.19b    | 0.07b    | 0.023   |
| TG (mmol/L)  | 0.36    | 0.33     | 0.32     | 0.02     | 0.705   |
| HDL (mmol/L) | 1.03    | 1.01     | 0.96     | 0.03b    | 0.614   |
| LDL (mmol/L) | 0.31a   | 0.30a    | 0.19b    | 0.02a    | 0.035   |
| Urea-N (mmol/L)| 1.23b   | 1.24b    | 1.19b    | 0.03b    | 0.023   |

SEM, pooled standard error of the means. Different superscript lowercase letters in the same row means significantly different at $P < 0.05$.

Abbreviations: CON, control; CTC, antibiotic (chlortetracycline); CWE, chestnut wood extract; HDL, high-density lipoprotein cholesterol; LDL, low-density lipoprotein cholesterol; TC, total cholesterol; TG, triglyceride.

1Data represented the mean value of 7 sample per treatment.
were found to be lower in broilers fed tannins containing thyme extract (Abdulkarimi et al., 2011). On the other hand, hypercholesterolemia and LDL concentration in tissue were associated with endothelial dysfunction and abnormal inflammation (Barbalho et al., 2009). Our study showed that supplementation of CWE could reduce the level of uric acid in serum of broilers than non-supplemented diets. Urea-N is a microbial product and harmful for bird’s health (Abd El-Hack et al., 2017). We hypothesized that serum uric acid level was closely related to higher crude protein retention in this experiment. A high concentration of urea-N in serum is a risk indicator of cardiovascular diseases, whereas the low concentration of uric acid has protective effects on oxidative stress in body (Glantzounis et al., 2005). In addition, the higher concentration of urea nitrogen in serum was reported as transport stressor in broilers (Pan et al., 2018a,b).

**CONCLUSION**

Broiler diets supplemented with CWE at 1,000 mg/kg level can be applied to improve antioxidant status, cholesterol metabolism, and growth performance without affecting normal meat quality. Thus, the supplementation of CWE as a potential natural antioxidant as well as an antibiotic substitute can be another strategy to improve the antioxidant status and growth performance in broilers.

**ACKNOWLEDGEMENTS**

This research was financially supported by the National Natural Science Foundation of China (31772612) and the Beijing Municipal Natural Science Foundation (6202019). The authors gratefully acknowledge Dr. Nicola Panciroli (Gruppo Mauro Silvachimica Srl; Cuneo, Italy) for his valuable suggestions on this experiment.

Conflict of Interest Statement: There is no conflict of interest relevant to this publication.
