Composition of the Kirsten Skeletal Collection at Stellenbosch University

The Kirsten Skeletal Collection is curated in the Division of Anatomy and Histology, Faculty of Medicine and Health Sciences, Stellenbosch University, South Africa. It comprises the largest documented cadaver-derived South African coloured skeletal collection in the world. Our aim in this paper is to present an inventory and characterise the identified skeletons in the Kirsten Skeletal Collection as well as provide a descriptive indication of what researchers can expect to encounter at the anthropology unit at Stellenbosch University. The skeletal material was derived mainly from the cadaver donation programme of the Division of Anatomy and Histology over a 58-year period (1957–2015). All pertinent information for each individual skeleton is entered into a database and a full skeletal inventory is established. The skeletal database registry was analysed to demonstrate the distribution of age, sex and population affinity of individuals in the collection. Currently, this collection consists of 1161 skeletons with known records. Despite differences in the age and sex composition, the skeletal profile in general reflects mainly the profile of the Western Cape population. Most individuals were born between 1920 and 1950, placing the Kirsten Skeletal Collection in the early to mid-20th century. The age at death for the greatest proportion (41.8%) of individuals was between 40 and 60 years. Current biological profile techniques in age, ancestry and sex estimation can be improved and, among others, new regional and ancestral specific standards for the biologically unique and diverse South African coloured population can be developed.

Significance:
- We present the largest documented skeletal collection of the South African coloured population in the world.
- This work contributes to the skeletal reference database for use by physical anthropologists and others.

Introduction

Human skeletal collections with known records are valuable for both teaching and research. Current research using human skeletal collections includes developing new techniques to test and standardise regional-specific data regarding osteometric measurements and physical observations. These reference points provide practical information for the estimation of biological profiles of unknown skeletons in both forensic anthropology and bioarchaeology, including estimation of age, sex and stature. Detailed descriptions of skeletal remains of known populations are used to confirm or contradict archaeological and social theories for past and present communities. Studies on skeletal collections include the physiological stresses and diseases experienced by the community that may have influenced their health status and physical attributes.

Nationally, the South African black population was estimated to be almost 52 million people during the 2011 physical census. South African blacks constitute the largest population group in the country at 79.2%. However, the regional population demographic of the Western Cape Province consists of 32.9% South African black, 15.7% South African white and 48.8% South African coloured. Unlike other provinces in South Africa, the Western Cape Province is composed of primarily the self-identified social group called ‘South African coloureds’. The Kirsten Skeletal Collection is reasonably representative of the Western Cape with mainly South African coloured individuals, providing a standard database of this area in South Africa. Although the Kirsten Skeletal Collection was established in the late 20th century, it is only in recent years that skeletons were intentionally added to the Collection for the purposes of research.

Our aim in this paper was to present an inventory of the osteological material in the Kirsten Skeletal Collection at Stellenbosch University and provide descriptive information to both national and international researchers interested in anthropological studies of the biologically heterogeneous South African coloured population.

Population demographic origin

South Africa is a multicultural nation with a rich biological history. For centuries, the southwestern corner of Africa was home to the oldest known lineage of modern humans – descendants of the original Khoikhoi (pastoralists) and the San (hunter-gatherers) populations. These two historical groups are collectively referred to as the Khoisan or the Khoe-San, and speak a distinctive click language. Although the Khoisan maintained an isolated ancient lifestyle for centuries and remained genetically distinct with unique physical characteristics from Europeans, Asian and other Africans, the genetic profiles of some tribes (such as the Khwe groups) show high proportions of Bantu-speaking admixture.

Linguistic and archaeological evidence indicates that the South African black population originated from the Niger–Congo linguistic phylogeny in the Cameroon–Nigeria grasslands. They migrated as part of the greater Bantu group to occupy much of the east and southern parts of Africa. Variants from this Bantu family in the south included the Nguni group (Xhosa, Zulu, Swati and Ndebele tribes) and the Southern (also called the Sotho-Tswana) groups (Southern Sotho, Northern Sotho, Tswana, Venda and Tsonga tribes).
The Nguni populations migrated southwards over many centuries with large herds of Nguni cattle. These migration patterns started around 2000 years ago followed by larger migration impressions around 1400 CE.\textsuperscript{14,15} When entering southern Africa, settlement patterns among the different tribes formed as a result of the settling of some groups along the way, while others kept moving; for example the Ndebele stayed in the north, the Swazi in the northeast, the Zulu towards the east and the Xhosa in the south.\textsuperscript{12}

Historical documents indicate that Portuguese sailors in the 1400s were the first Europeans to have contact with these tribes. The European community settled at the Dutch-controlled Cape Colony between 1652 and the 19th century. Other immigrant groups were mainly descendants from the French, Germans, Greeks and Italians. The British settlers colonised the Cape in the mid-1800s.\textsuperscript{17,18} The Indian/Asian population originated from Indian and Chinese immigrants, as well as slaves imported to relieve the labour burden in the fast-growing Cape settlement. These slaves were shipped to the Cape colony from Indonesia, southern China and Madagascar, among others.\textsuperscript{16,19}

Marriages amongst white European men and women from either the free black populations or Khoisan were common during the early Dutch settlement era.\textsuperscript{17,20} Colonisation and migration from many parts of the world became the foundation to modern variation in South African groups, and produced a heterogeneous new population with distinctive physical and biological traits and genetic variations.\textsuperscript{5} As a result of the eradication of slavery in 1834–1838, the newly formed self-identified population was named the Cape Coloureds,\textsuperscript{7,18} and is today known as the South African coloured population. During the early 1800s, the number of cross-cultural relationships declined\textsuperscript{21}, and later during the 1900s, racism established by apartheid laws further reduced cross-population gene flow\textsuperscript{6,22}.

Apartheid in South Africa was a system of racial separation that was enforced by the minority governing party (the white population) that ruled between 1948 and 1994.\textsuperscript{23,24} Under this ruling, African people that were a product of the Bantu expansion, were grouped as black people, while people with an admixture of mixed origin, including Khoisan, were classified as coloureds.\textsuperscript{20} The Population Registration Act of 1950 was used to categorise all South Africans as black, white, Indian or coloured during the apartheid reign.\textsuperscript{20} Census in the apartheid era was underreported, particularly concerning the black population because of legislation such as the Native Areas Amendment Bill and the Group Areas Act. Such legislation resulted in the number of people in South Africa being grossly underestimated.\textsuperscript{20} The apartheid laws were introduced to force population segregation by assigning certain areas for each population group. This forced segregation with geographical parting of these groups directly limited admixture of different population groups.\textsuperscript{6,25} Although apartheid was abolished in 1994, the newly formed different populations in South Africa have tended to persist within their socially defined populations, and produced a heterogeneous new population with distinctive physical and biological traits and genetic variations.\textsuperscript{5} As a result of the eradication of slavery in 1834–1838, the newly formed self-identified population was named the Cape Coloureds,\textsuperscript{7,18} and is today known as the South African coloured population. During the early 1800s, the number of cross-cultural relationships declined\textsuperscript{21}, and later during the 1900s, racism established by apartheid laws further reduced cross-population gene flow\textsuperscript{6,22}.

As a result of the limited intercultural relationships still today, genetic variation within groups is decreasing and variation between groups is increasing.\textsuperscript{6,26}

Materials and methods

Acquisition and processing of skeletal material for the Collection

The Department of Anatomy (later changed to the Division of Anatomy and Histology) at Stellenbosch University was established in 1957. Initially, medical students were trained under the guidance of Professor J.F. van E. Kirsten in the Mike de Vries building (formerly known as D.F. Malan building) on the main campus located in Stellenbosch, South Africa. Kirsten, a qualified general surgeon, was one of the first five professors appointed at the newly established medical faculty, and the first to perform the task of collecting skeletal material for study. The anatomy department relocated over time – initially to Karl Brenner Hospital in Bellville and then, during the 1970s, to the Tygerberg Medical Campus adjacent to the then newly built Tygerberg Hospital. It was during this time that the J.F. van E. Kirsten Museum of Morphology and the Kirsten Skeletal Collection was established, in Kirsten’s honour. The initial cadavers used for anatomy training of medical students at Stellenbosch University were received from the University of Pretoria and the University of the Witwatersrand from 1957 to 1960. The first cadavers embalmed at Stellenbosch University’s Department of Anatomy were received from Karl Brenner Hospital in 1960. From 1957 onwards, a number of the dissected cadavers were skeletonised, except during a brief period in the 1990s when the Department did not have the capacity or staff to skeletonise cadavers. Between 30 and 40 skeletons are currently added to the collection on an annual basis.

Under the Human Tissue Act, Act 65 of 1983\textsuperscript{24}, the more recent National Health Act\textsuperscript{27} (Act 61 of 2003), and the protection of the regional inspector of Anatomy, the Division of Anatomy and Histology is allowed to receive cadavers for both teaching and research purposes. The cadavers received are either consented donations or unclaimed bodies of persons who died from natural causes in the Western Cape region, specifically the Northern suburbs of Cape Town and surrounding rural towns. Consented donations are individuals (or their family members) who bequeathed their bodies to the University. So-called ‘unclaimed’ bodies are those for whom no next-of-kin could be traced, either by the institution at which the person died or by any other means. Unclaimed does not necessarily imply that the person is unknown. If, however, family or friends are traced at a later stage when the cadaver is already prepared at the Division, whoever lays legal claim to the body is allowed to remove it for burial. The majority of unclaimed bodies received are from communities with a low socio-economic status. The cadaver intake does not include any unnatural or traumatic deaths as South African legislation requires that all bodies resulting from unnatural deaths be autopsied by the Forensic Pathology Services.\textsuperscript{28} Autopsied bodies cannot be embalmed, therefore these bodies cannot be entered into the cadaver programme. Although the skeletal collection consists largely of individuals obtained through this cadaver intake programme, a small number of unidentified fragmented individuals with archaeological or forensic (cases received for biological profile assessment from the police) origins are present in the collection. Past curators accessioned these remains into the collection. Material accessioned in the collection cannot be removed from the database; however, these materials are not used for purposes of research.

Cadavers are used for dissection in the anatomy training of undergraduate and postgraduate medical and allied healthcare students. Upon intake at the Division of Anatomy and Histology, all personal information available on the cadaver, as well as the intake number given to the cadaver, is recorded in the cadaver register of the Division. This information includes age, sex, date of birth, date of death, last known residential address, hospital/funeral home from which the body was acquired and previously self-identified ancestry. Medical records of the individuals are not made available; only cause of death is provided. Since 2011, intake information has included the person’s weight at reception and full-face and profile photographs. The cadavers are subsequently embalmed and stored. Before the cadavers are used, a full-body X-ray is taken using the Lodox® Statscan\textsuperscript{®} digital imaging system (Figure 1a). After dissection, excess soft tissue is manually removed from the cadavers and the bones are immersed in water. The remains are carefully boiled at relatively low temperature (60–80 °C). Following the boiling process, the remaining tissue on the bones is removed with a scalpel and forceps, whereafter the bones are washed with warm soapy water, and a scrubbing brush is used to lightly scour the surfaces of the bones until smooth. The bones are then air-dried at room temperature and bleached with a bleaching agent. The Kirsten Collection intake number is then recorded on each dried bone with a permanent marker.

The processed skeletal material is registered and curated at the Kirsten Skeletal Collection Ossuary at the Division of Anatomy and Histology. All pertinent information for each individual skeleton is entered into a database and a full skeletal inventory is established. At least 350 complete skeletons in anatomical order have been scanned with the Lodox® Statscan\textsuperscript{®} since 2014 (Figure 1b). The practice of correlating these scans with the cadaver scans taken prior to maceration will continue. Projects have been initiated in collaboration with radiologists.
to use these scans to compare disease lesions on bone, and in collaboration with forensic anthropologists to use these scans to set science-based X-ray standards for identifying human remains.

This study on the skeletal material was ethically cleared by the Health Research and Ethics Committee of Stellenbosch University and conforms to the principles stipulated by the Declaration of Helsinki (1964). The allocated ethics number is S13/05/100.

Results

The Kirsten Skeletal Collection currently consists of 1161 skeletons, which, according to the known cadaver records, represent mostly individuals from the Western Cape Province, South Africa. Although the overall preservation of the skeletal elements is good, loans to students, other departments and institutions in the past, have resulted in total or partial loss of some of the material, which has reduced the number of full skeletons available for study. As a result, the collection currently has 674 (58%) complete and 342 (29.5%) incomplete individuals from the cadaver programme. However, 103 (8.9%) cadaver-derived individuals are on loan or at an unknown location. Moreover, this collection hosts a small number (3.6%) of fragmented individuals with archaeological or forensic origins (Table 1).

The greatest proportion (42%) of individuals in the collection were born between 1920 and 1949, with the oldest born in 1855 and the most recent in 1991. Most (54.1%) individuals in the collection died between 1970 and 1989 (Figure 2).

Table 1: The state of the skeletal remains in the Kirsten Skeletal Collection

| State                        | Description                                                                 | n (%) |
|------------------------------|-----------------------------------------------------------------------------|-------|
| Complete                     | A complete individual that may be either articulated or unarticulated       | 674 (58.0) |
| Incomplete (cranial only)    | A complete skull (calvarium, cranium and mandible) without associated post-cranial remains | 60 (5.2) |
| Incomplete (fragmented)      | Remains that have only a few bones present because specific bones are on loan to institutions, departments or students on a semi-permanent basis or have been lost through loan to students | 197 (16.9) |
| Incomplete (post-cranial only) | Post-cranial remains which are not associated with a skull               | 85 (7.3) |
| On loan (complete)           | Complete remains that are on loan to institutions, departments or students on a semi-permanent basis, either articulated or unarticulated | 58 (5.0) |
| Missing/unknown              | Remains for which the current location is unknown                          | 45 (3.9) |
| Archaeological/forensic origin | Skeletons received from sources other than the cadaver programme          | 42 (3.6) |

Figure 1: Cadaver K96/13 received in 2013: (a) Lodox® scan of cadaver prior to dissection by medical students and (b) Lodox® scan of skeleton in anatomical order (anthropology number An1352).

Figure 2: Frequency distributions for year of birth and year of death for the skeletons in the Kirsten Skeletal Collection.

The collection comprises individuals from three main socially defined population groups, namely South African coloured (59.7%), South African black (16.5%) and South African white (12.2%). The regional population composition of the Western Cape Province differs considerably from that of other provinces in South Africa. According to the census of 2011, the black population group has the highest proportion (of over 79%) in all provinces with the exception of the Western Cape (32.9%). The South African coloured population is the highest proportion in the Western Cape (48.8%). Therefore, it is expected that a larger South African coloured population is apparent in the Kirsten Skeletal Collection, which is derived mainly from Western Cape individuals. However, the South African coloured population in the Western Cape declined from 58.3% in 1991 to 48.8% in 2011.

Cadavers were mostly acquired from the large teaching hospitals in the region, namely Tygerberg Hospital (32%), followed by Karl Bremer Hospital (10.1%), both in the Bellville area, and Groote Schuur Hospital (6.8%) in Cape Town. A total of 15.6% of individuals were received directly from undertakers as paupers and 14.6% were from unknown sources or sources that had not been documented (Table 2). Available records for the last residence of individuals in the Kirsten Skeletal Collection indicate that the greatest proportion were from the Cape Town metropole (42.3%) and surrounding towns (19.1%) (Table 3).
Table 2: Locations or institutions from which bodies were received

| Location/institution       | n     | (%)  |
|----------------------------|-------|------|
| Tygerberg Hospital         | 379   | (32.6) |
| Karl Bremer Hospital       | 117   | (10.1) |

| Total | 1161 | 156 | 36 | 87 | 55 | 464 | 229 | 1 | 1 | 12 | 6 | 3 | 109 |

BM, black male; BF, black female; WM, white male; WF, white female; CM, coloured male; CF, coloured female; KM, Khoisan male; KF, Khoisan female; KU, Khoisan unknown sex; UM, unknown ancestry male; UF, unknown ancestry female; US, unknown sex; UA, unknown ancestry

The mean age at death for the entire collection is 51.0 years and ranges from 10 to 103 years. The greatest proportion (41.8%) of individuals died between the ages of 40 and 60. The mean age at death for female individuals from all population groups is 49.7 years (10 to 103 years) and for male individuals, 51.7 years (15 to 100 years) (Table 4). When comparing the age composition of the three populations (black, white and coloured), both male and female groups for the black and coloured populations show the highest proportion of individuals died in the adult (40–60 years) age category, whereas more male and female individuals in the white population were in the old adult (61–80 years) age category at death (Table 4). The average age at death for the black population was 51.0 years for males and 41.5 years for females; for the coloured population was 50.6 years for males and 45.5 years for females; and for the white population was 62.4 years for males and 66.9 years for females.

The sex ratio of the collection demographics is not representative of the South African population. Sex distribution determined by censuses indicate that the South African population is predominantly female. However, the female individuals in this collection are under-represented in all three population groups (coloured, black and white), with the majority (61.6%) of skeletons being male (Table 5).
Table 5: Population and sex composition of the individuals in the Kirsten Skeletal Collection

| Population group | n (%) | Male | Female | Unknown sex |
|------------------|-------|------|--------|-------------|
| Coloured         | 693 (59.7) | 464 | 229 | – |
| Black            | 192 (16.5) | 156 | 36 | – |
| White            | 142 (12.2) | 87 | 55 | – |
| Khoisan          | 14 (1.2) | 1 | 1 | 12 |

| Other | 64 (5.5) |
| Unknown/natural causes | 344 (29.6) |

Discussion

The Western Cape Province of South Africa has a rich genetic history, arising from many parts of the world including the local ancient Khoisan population1-3, the greater Bantu groups from the Niger–Congo phylum4-10, European settlers11-13, and slaves from the East14-16. Marriages amongst the different population groups were once common17-22, and produced a heterogeneous new and genetically unique population in the Western Cape, until apartheid was introduced and resulted in a drastic decrease in cross-population gene flow20-25.

The origin of the osteological material in the Kirsten Skeletal Collection has been mainly cadavers used during anatomy training of medical students since the anatomy department’s origin in the late 1950s. Research projects on this material were initiated only in recent years. While in many instances, the South African coloured communities, as it is derived from primarily Western Cape individuals, some cultural groups in South Africa are less willing to donate their bodies to science than others. Although organ donation is allowed, violation of the human body, living or dead, is forbidden in, for instance, Islam26 and therefore bodies are not donated for use in medical training by this group. The black population group is hesitant to donate bodies because of traditional African beliefs that the body is not separate from the soul and they need to be buried as an integrated whole. This means that, in general, black individuals are against body donation, as reflected in the relatively low percentage of skeletal material in the collection (16.5%) as opposed to the high percentage of black individuals (32.9%) residing in the Western Cape, according to the most recent population census. Socio-economic circumstances may be the reason for older white people to donate their bodies while black people are more likely to be migrating labourers with no known family in the region. In many instances, the South African coloured communities, as a result of low socio-economic circumstances, lack the means to host a funeral for the deceased and opt to donate the bodies for medical use.24

Conclusion

Data were presented on 1161 individuals in the Kirsten Skeletal Collection, derived mainly from the cadaver donation programme over a 58-year period (1957–2015). The skeletal profile in general, despite differences in the age and sex composition of three population groups, reflects predominantly the profile of the Western Cape population. The Kirsten Skeletal Collection is unique compared to other known skeletal collections in South Africa2-5 in that the majority of the individuals are from the heterogeneous South African coloured population. Current biological profile techniques in age, ancestry and sex estimation should be improved and new regional and ethnic specific standards can be developed. Researchers may contact the corresponding author for...
information regarding access to the collection for research. The Kirsten Skeletal Collection retains great potential to contribute to a wealth of future research projects in skeletal biology and related fields, and may be utilised as long as the origin of the remains is acknowledged and accounted for by the use of appropriate methods.

Acknowledgements

We thank Dolf van Rensburg, Ben Jooste and Basil Veenendaal for their assistance with the development of the Kirsten Collection and Danni Perreira for editing. We also thank the anonymous reviewers for their input. A special thank you goes to the people who donated their bodies to science.

Authors’ contributions

A.A. was the lead author, and collected and analysed the data and wrote the first draft. L.M.G. supervised the study and assisted with data analysis and editing, E.G. assisted with data collection. All authors contributed to critical review and revising of the article and approved the final version.
