ABSTRACT: Exact field theory dualities can be implemented by duality domain walls such that passing any operator through the interface maps it to the dual operator. This paper describes the S-duality wall of four-dimensional \( \mathcal{N} = 2 \) SU(\( N \)) SQCD with \( 2N \) hypermultiplets in terms of fields on the defect, namely three-dimensional \( \mathcal{N} = 2 \) SQCD with gauge group U(\( N - 1 \)) and \( 2N \) flavours, with a monopole superpotential. The theory is self-dual under a duality found by Benini, Benvenuti and Pasquetti, in the same way that \( T[SU(N)] \) (the S-duality wall of \( \mathcal{N} = 4 \) super Yang-Mills) is self-mirror. The domain-wall theory can also be realized as a limit of a USp(\( 2N - 2 \)) gauge theory; it reduces to known results for \( N = 2 \). The theory is found through the AGT correspondence by determining the braiding kernel of two semi-degenerate vertex operators in Toda CFT.

1 Introduction

Extended operators, such as Wilson and 't Hooft loops [1, 2], surface operators [3–5], and domain walls [6–8] can serve as order parameters [1, 2, 9] and help probe dualities of gauge theories. Exact all-scale dualities such as S-duality map all correlators of one theory to the dual theory through some dictionary that must be worked out on a case by case basis. For instance, S-duality of four-dimensional $\mathcal{N} = 2$ supersymmetric gauge theories [10, 11] interchanges Wilson (electric) and 't Hooft (magnetic) loop operators [12–15], as befitting of this generalization of electric-magnetic duality.

Given an exact duality between theories $\mathcal{T}_1$ and $\mathcal{T}_2$, what happens if one dualizes one half-space, say $y \geq 0$? Start with $\mathcal{T}_1$ on all of space. After dualizing, the system should be described by $\mathcal{T}_1$ for $y < 0$ and $\mathcal{T}_2$ for $y > 0$, separated by a codimension 1 interface (wall) at
Only a specific choice of interface can reproduce the physics of the original system. For instance, the position of the wall should not be observable so it must be topological away from operator insertions. When the interface passes through an operator inserted in the region described by theory $T_2$, the operator should be replaced by its dual description in theory $T_1$ to keep correlators fixed. Such duality walls [8] are thus a compact way to encode how dualities act on operators [16–22].

The duality wall can often be described by coupling bulk fields of theories $T_1$ and $T_2$ near the wall to additional degrees of freedom that live only on the wall. To determine what fields to put on the wall, one should decouple the bulk theories by making their couplings weak. This is impossible to do directly in the most common case of a weak-strong duality, as making the bulk coupling small on one side of the wall makes the other bulk theory strongly coupled. To avoid this we begin with a system described by theory $T_1$ throughout space, with a Janus domain wall, namely a $y$-dependent coupling that varies sharply near $y = 0$ from some value to another. Now dualize the $y > 0$ side to get theories $T_1$ and $T_2$ for $y \geq 0$, separated by a duality wall as before. The couplings on the two sides can now be sent to zero independently to decouple bulk dynamics from the theory on the interface. If enough is known about Janus walls the codimension 1 theory can be deduced [8, 23–30].

For 4d $\mathcal{N} = 4$ super Yang-Mills (SYM), 1/2 BPS domain walls and boundary conditions were extensively studied in [6–8] (and 1/4 BPS ones in [31, 32]). S-duality of $\mathcal{N} = 4$ SYM changes the gauge group $G$ to its Langlands dual $L^G$, and the S-duality wall is described by gauging global symmetries $G \times L^G$ of a 3d $\mathcal{N} = 4$ theory $T[G]$ using the 3d restrictions of the 4d vector multiplets on both sides of the wall. The analysis in [8] largely relies on realizing $\mathcal{N} = 4$ SYM as the world-sheet theory of $N$ D3 branes in the $G = SU(N)$ case (other classical gauge groups are obtained using O3 planes), realizing boundary conditions by ending D3 branes on D5 or NS5 branes and noting that S-duality of $\mathcal{N} = 4$ SYM descends from S-duality in IIB string theory. The $T[SU(N)]$ theory is found to be given by the following brane configuration from which one reads a quiver gauge theory description:

\[
\text{D5}(012789) \quad \text{D3}(0126) \quad \text{NS5}(012345) \quad \Rightarrow \quad \begin{array}{c}
\begin{array}{c}
N \\
N-1 \\
\cdots \\
2 \\
1
\end{array}
\end{array}
\]

More precisely, $T[SU(N)]$ is the infrared limit of the gauge theory with gauge group $U(N-1) \times U(N-2) \times \cdots \times U(1)$ and hypermultiplets in the bifundamental representation of each pair $U(k) \times U(k-1)$, as well as $N$ hypermultiplets in the fundamental representation of $U(N-1)$, which have an $SU(N)$ flavour symmetry. Since IIB S-duality interchanges D5 and NS5 branes, leaving the brane diagram essentially invariant, $T[SU(N)]$ is self-mirror so its $U(1)^{N-1}$ topological symmetry enhances to another\(^1\) $SU(N) = L^G SU(N)$. However, this construction through IIB strings does not apply to S-duality of 4d $\mathcal{N} = 2$ theories.\(^2\)

\(^1\)Throughout we will ignore global aspects of flavour symmetries: here one $SU(N)$ should be $PSU(N)$.

\(^2\)One exception is that the world-volume theory of fractional D3 branes at the center of an orbifold $\mathbb{R}^4/\mathbb{Z}_k$ is a 4d $\mathcal{N} = 2$ necklace quiver. However, IIB string theory only provides $SL(2,\mathbb{Z})$ S-dualities acting on all gauge couplings at once, while there exists a much richer set of dualities acting “locally” on the quiver.
For the large class of 4d $\mathcal{N} = 2$ SU($N$) gauge theories obtained by twisted dimensional reduction of 6d $(2,0)$ $A_{N-1}$ superconformal theory on a punctured Riemann surface $\Sigma$, the AGT correspondence provides another handle [33] (see also [34–36]). It relates observables of the 4d theory on an ellipsoid $S^4_\mathcal{B}$ to observables of the Toda CFT on $\Sigma$, a generalization of the Liouville CFT with a larger symmetry algebra $W_N$. In particular, an S-duality domain wall placed along the equator (or a parallel $S^3_\mathcal{B}$ of $S^4_\mathcal{B}$) corresponds to a certain $W_N$ braiding transformation [15]. From the integral kernel that braids certain $W_N$ primary operators of the Toda CFT one can thus deduce the partition function of the S-duality domain wall, hence the $S^3_\mathcal{B}$ partition function of its description as a 3d gauge theory, as we explain in Section 2. One is then left with finding a 3d gauge theory with the given $S^3_\mathcal{B}$ partition function. This strategy was applied in [23] to the mass deformation of 4d $\mathcal{N} = 4$ and in [37] to 4d $\mathcal{N} = 2$ SU(2) SQCD with 4 fundamental hypermultiplets.

While we concentrate on 4d $\mathcal{N} = 2$ SU($N$) SQCD with 2 $N$ fundamental hypermultiplets, the 3d $\mathcal{N} = 2$ description of the SQCD S-duality wall that we give momentarily also implements S-duality of any balanced SU($N$) gauge node in a 4d $\mathcal{N} = 2$ quiver (see the conclusion section). We have not worked out the case of $N_f < 2N$ hypermultiplets, but it should simply amount to making some hypermultiplets massive.

We determine the relevant braiding kernel (4.4) in Section 4 as a continuation of braiding matrices (3.42) worked out in Section 3 using 2d CFT pentagon relations. Comparing it to explicit expressions of $S^3_\mathcal{B}$ partition functions from localization [38–40] we describe in Section 5 the S-duality wall of 4d $\mathcal{N} = 2$ SU($N$) SQCD as 3d $\mathcal{N} = 2$ U($N$−1) SQCD with a monopole superpotential on the wall, coupled to the 4d theories on both sides of the wall. We then find evidence that the 3d theory can also be obtained as a certain limit of an USp($2N - 2$) theory, in which some symmetries are more manifest. Altogether,

$$\langle \text{S-duality wall} \rangle = Z_{\text{4d}}^{\mathcal{N} = 2} \begin{array}{c} \text{U}(N-1) \\ \text{N} \end{array} \longrightarrow_{\text{S-duality}} \begin{array}{c} \text{2N} \\ \text{4d} \end{array} \bigg) \lim_{\mu \to \pm \infty} Z_{\text{USp}(2N-2)}^{\mathcal{N} = 2} \begin{array}{c} \text{N} \\ \text{4d} \end{array} \bigg).$$

In these quiver, the upper and lower round nodes labelled $N$ denote SU($N$) gauge groups of the 4d theories on both sides of the wall, the diagonal edges stemming from them are 2$N$ hypermultiplets (again on both sides of the wall) that share a common SU(2$N$) flavour symmetry across the wall. The rest of the quiver describes the 3d $\mathcal{N} = 2$ theory on the wall: a U($N$−1) or USp($2N - 2$) vector multiplet coupled to 2$N$ fundamental and $N + N$ antifundamental chiral multiplets. The labels $\pm \mu$ will be explained shortly. Additionally, the 3d and 4d matter multiplets are coupled by a cubic superpotential $W$ along the defect:\footnote{Version 1 of this paper was lacking $V_+$ and $V_-$ so the proposed 4d/3d system had too many symmetries. Thanks to Sara Pasquetti for pointing this out. In fact, the corrected 3d theory with $W = V_+ + V_-$ is self-dual: see [41] for $N = 2$ and [42] (after our version 1) for all $N$. This duality turns out to make the USp($2N - 2$) theory unnecessary for our purposes, but we keep it as an interesting variant.}

$$W = \sum_{f=1}^{2N} \sum_{s=1}^{N} \left( \Phi_{fs}|_{3d} \tilde{g}_s q_f + \Phi'_{fs}|_{3d} \tilde{g}'_s q_f \right) + \begin{cases} V_+ + V_- & \text{for the U}(N - 1) \text{ theory,} \\ Y & \text{for the USp}(2N - 2) \text{ theory.} \end{cases}$$ (1.3)
Here, \( \tilde{q}_s \) and \( \tilde{q'}_s \) denote the \( 2N \) antifundamental chiral multiplets and \( q_f \) the \( 2N \) fundamental ones, while \( \Phi|_{3d} \) and \( \Phi'|_{3d} \) are limits of 4d hypermultiplets at the interface. Following standard notations, \( V_\pm \) are monopole operators with \( U(1)_T \) charges \( \pm 1 \) in the \( U(N-1) \) theory, while for the \( USp(2N-2) \) theory the monopole is denoted by \( Y \) (see, e.g., \cite{43}). Coefficients of the superpotential cannot be determined by our methods.

The rest of this paper is organized as follows. Section 2 explains the AGT correspondence relating the S-duality domain wall of 4d \( \mathcal{N} = 2 \) SU(\( N \)) SQCD to a \( W_N \) braiding kernel\(^4\) and gives an introduction to the Toda CFT. Section 3 evaluates some braiding matrices (3.42) which are special cases of the braiding kernel when an operator is fully degenerate. Section 4 generalizes these discrete results to a continuous braiding kernel (4.4). It describes how this integral kernel reduces to Liouville CFT braiding kernels [44, 45] and proves that the kernel obeys a shift relation deduced from Moore-Seiberg pentagon identities [46]. A reader with no interest in Toda CFT can jump directly to section 5, where we extract the above gauge theory description of the S-duality wall from the braiding kernel and explain how continuous flavour symmetries and various \( \mathbb{Z}_2 \) symmetries (including self-dualities) match between the different descriptions. We conclude in section 6 with some remarks on class S quiver gauge theories.

2 AGT relation

This section describes supersymmetric localization for 4d \( \mathcal{N} = 2 \) theories, then translates S-duality domain walls of SU(\( N \)) SQCD to the 2d CFT language using the AGT correspondence.

2.1 Localization

For a given choice of supercharge \( Q \) under which a path integral is invariant, localization reduces the path integral to a simpler integral over \( Q \)-invariant field configurations only.\(^5\) As an IR cutoff we place the theory on the ellipsoid \( S_b^4 \) given in coordinates as

\[
x_0^2 + b^{-2}(x_1^2 + x_2^2) + b^2(x_3^2 + x_4^2) = 1.
\]

Preserving supersymmetry requires non-trivial background fields [35]. There exists another deformation of the sphere in which the parameter \( b \) is complex rather than real [36]. Domain walls will be placed at constant \( x_0 \), such as the equator \( S_b^3 \) at \( x_0 = 0 \).

The partition function of 4d \( \mathcal{N} = 2 \) theories on \( S_b^4 \) was computed [35, 47] using a supercharge \( Q \) whose square rotates the ellipsoid in the planes \( (x_1, x_2) \) and \( (x_3, x_4) \) and leave two poles \( x_0 = \pm 1 \) fixed. In \( Q \)-invariant configurations one vector multiplet scalar
takes a constant value $i a$ and other fields vanish, except at the North and South poles where there can be instantons and anti-instantons. The exact $S^4_b$ partition function is then

$$Z_{S^4_b} = \int da e^{-S_4(a,x,\bar{x})} Z_{\text{1-loop}}(m,a) Z_{\text{inst}}(m,a,x) Z_{\text{anti-inst}}(m,a,\bar{x})$$

where the real scalar $a$ runs over the gauge Lie algebra, $x$ stands for exponentiated gauge coupling constants and $m$ for the masses. The integrand consists of a classical contribution $\exp(-S_{\text{cl}})$ evaluated at the saddle point (away from the poles), a one-loop determinant due to fluctuations around the saddle point, and (anti)instanton contributions at the poles, which depend (anti)holomorphically on $x$. These instanton partition functions are power series that normally converge in a finite region near the weakly-coupled limit $x \to 0$. After reducing the integral to the Cartan algebra, combining the resulting Vandermonde determinant with $Z_{\text{1-loop}}$, and factorizing the classical contribution into holomorphic functions of $x$ and $\bar{x}$, one gets (2.3) below. S-dual theories have equal ellipsoid partition functions, hence

$$Z_{S^4_b} = \int da C(m,a)f(m,a,x)f(m,a,\bar{x})$$

$$= \int da D C_D(m,a_D)f_D(m,a_D,x_D)f_D(m,a_D,\bar{x}_D).$$

While the global symmetries and masses $m$ of the two 4d theories are shared up to permutations, their matter content and coupling constants may be very different. For a fixed $\bar{x}$ (and $\bar{x}_D$) the two integral representations express $Z$ in different bases of holomorphic functions $f$ and $f_D$, hence there should exist a change of basis $B(m,a,a')$, called S-duality kernel:

$$f(m,a,x) = \int da' B(m,a,a') f_D(m,a',x_D).$$

Let us repeat the localization computation, but with a Janus domain wall that interpolates between $x$ in the North half-ellipsoid and $x'$ in the South half-ellipsoid. While the $Q$-invariant field configurations are unaffected by the wall, the (anti)instanton contributions from the North and South poles are evaluated using $x$ and $\bar{x}'$, respectively. The classical contribution is affected in a similar way [15, section 5], and one gets

$$\langle \text{Janus wall} \rangle = \int da C(m,a)f(m,a,x)f(m,a,\bar{x}').$$

When the couplings are S-dual ($\bar{x}_D = \bar{x}$), one can apply S-duality (2.5) to the South half-ellipsoid and obtain a duality wall:

$$\langle \text{S-duality wall} \rangle = \int da \int da' C(m,a) B(m,a,a') f(m,a,x)f_D(m,a',x_D).$$

On the other hand, consider the 4d $\mathcal{N} = 2$ theory on $S^4_b$ with coupling $x$ throughout the ellipsoid, coupled to 3d fields on the equator. $Q$-invariant configurations of such a 4d/3d system have constant vector multiplet scalars $i a$ and $i a'$ on the two halves of $S^4_b$, instantons at each pole, and possibly additional non-trivial field configurations on the 3d equator. The contribution from 3d fields is simply the $S^3$ partition function of the theory
obtained by freezing the 4d fields to their values \((ia, ia')\). The 4d classical and instanton contributions combine as before into \(f(m, a, x)\) and \(f_D(m, a', \bar{x})\) (provided an appropriate Chern-Simons term is included on the wall), and finally 4d one-loop determinants on each half-ellipsoid are functions of \((m, a)\) and of \((m, a')\). Altogether, (2.7) can be reproduced provided one finds a 3d theory whose ellipsoid partition function is essentially \(B(m, a, a')\):

\[
Z_S^b(m, a, a') = \frac{C(m, a)B(m, a, a')}{Z_{1\text{-loop}}^\text{half-ellipsoid}(m, a)Z_{1\text{-loop}}^\text{half-ellipsoid}(m, a')}.
\]  

(2.8)

In particular, the 3d partition function should depend on 4d masses and vector multiplet scalars \((m, a, a')\) which lie in the Cartan algebras of the global symmetry group (shared by the two 4d theories) and of both gauge groups. The 3d theory must therefore contain fields charged under each of these symmetries. For instance, the domain wall theory \(T[\text{SU}(N)]\) of 4d \(\mathcal{N} = 4\) SU\((N)\) SYM (1.1) has a (non-manifest) global symmetry \(U(1) \times \text{SU}(N)^2\).

We are interested in 4d \(\mathcal{N} = 2\) SU\((N)\) SQCD with 2\(N\) flavours. Let \(m_f (f = 1, \ldots, 2N)\) be the masses of these hypermultiplets. S-duality inverts the \(U(1)\) subgroup of the \(U(2N)\) flavour symmetry: namely masses in the dual theory are \(m_f - 2m\), where \(m = \frac{1}{2N} \sum f m_f\).

The 3d gauge theory description, which we find in section 5, must thus have the flavour symmetry \(U(1) \times \text{SU}(2N) \times \text{SU}(N) \times \text{SU}(N)\) (up to discrete factors). This symmetry is explicitly broken by \((m, a, a')\).

To find this 3d gauge theory description we must evaluate the right-hand side of (2.8). The relevant structure constants \(C(m, a)\) are known. The one-loop determinants of 4d vector and hypermultiplets are only known on the full ellipsoid and not on a half-ellipsoid. We take as inspiration the analogous situation in two dimensions: sphere one-loop determinants involve a combination \(\Gamma(x)/\Gamma(1-x)\) while hemisphere ones involve \(\Gamma(x)\) or \(1/\Gamma(1-x)\) depending on boundary conditions [48–50]. In four dimensions, we note that the one-loop determinant of a hypermultiplet of mass \(m\) is\(^6\) \(\Gamma_b\left(\frac{b+b^{-1}}{2} + im\right)\Gamma_b\left(\frac{b+b^{-1}}{2} - im\right)\).

It is thus natural to propose that the one-loop determinant on a hemisphere (or rather a half-ellipsoid) is a single one of these two \(\Gamma_b\) functions.\(^7\) The situation is similar for vector multiplets. Even if the proposal turns out to be incorrect, our main statement identifying what 3d theory to couple to the two 4d theories will hold, since one-loop determinants depend on \(a\) and \(a'\) separately. The most important ingredient in (2.8) is the S-duality kernel \(B\), which mixes \(a\) and \(a'\).

### 2.2 Toda CFT

To determine the kernel \(B\) we will use the AGT correspondence [33], found by remarking that the various factorizations (2.3) and (2.4) of \(Z\) into holomorphic factors are reminiscent of conformal block decompositions in 2d CFT. Observables of 4d \(\mathcal{N} = 2\) SU\((N)\) gauge theories (of class S) on \(S^4_b\) are equal to observables in the \(A_{\mathcal{N} - 1}\) Toda CFT.

---

\(^6\)See section 2.3 for properties of special functions.

\(^7\)This was previously suggested for instance in [41, page 24] and [51, page 29].
This generalization of the Liouville CFT (the case $N = 2$) has a symmetry algebra $W_N$ (for $N = 2$, the Virasoro algebra). We use standard notations. The vertex operators $\hat{V}_\alpha$, whose momentum $\alpha$ depends on $N - 1$ parameters, are $W_N$ primaries of dimension $\Delta(\alpha) = \frac{1}{2} \langle \alpha, 2Q - \alpha \rangle$. They are invariant under Weyl transformations, which permute their components $\langle \alpha - Q, h \rangle$. Among these primary operators we call the one-parameter class of momenta $\alpha = \kappa h_1$ semi-degenerate, or simple, and the discrete set $\alpha = -Kbh_1$ (for integer $K \geq 0$) fully degenerate.

The $S^4_N$ partition function of 4d $N = 2$ SQCD is then equal to a sphere correlator of two generic and two simple vertex operators:

$$Z_{S^4_N}(\text{SQCD}) = |x|^{2\gamma_0} |1 - x|^{2\gamma_1} \langle \hat{V}_{\alpha_3}(\infty) \hat{V}_{\kappa_1 h_1}(1) \hat{V}_{\kappa_2 h_1}(x, \bar{x}) \hat{V}_{\alpha_1}(0) \rangle$$

(2.9)

The cross-ratio $x$ of their positions is the exponentiated gauge coupling, mapped to $1/\bar{x}$ by S-duality. The unimportant exponents $\gamma_1$ can be fixed by matching Toda CFT and gauge theory asymptotics as $x \to 0, \infty$. The momenta $\alpha_1$ and $\kappa_2 h_1$ encode $N$ hypermultiplet masses and $\alpha_3$ and $\kappa_4 h_1$ the other $N$. The Toda CFT correlator thus does not make all gauge theory symmetries explicit, which leads to various sign asymmetries. Momenta are

$$\begin{align*}
\alpha_1 &= Q + \sum_{j=1}^{N} (im_j h_j) \\
\kappa_2 &= N \left( \frac{b + b^{-1}}{2} - \frac{1}{N} \sum_{j=1}^{N} im_j \right) \\
\alpha_3 &= Q - \sum_{j=1}^{N} (im_{j+N} h_j) \\
\kappa_4 &= N \left( \frac{b + b^{-1}}{2} + \frac{1}{N} \sum_{j=1}^{N} im_{j+N} \right).
\end{align*}$$

(2.10)

From the Toda CFT point of view, the two $S$-dual decompositions (2.3) and (2.4) of the partition function are conformal block decompositions obtained by taking the operator product expansion (OPE) of $\hat{V}_{\kappa_2 h_1}(x, \bar{x})$ with either $\hat{V}_{\alpha_1}(0)$ ("s-channel decomposition") or with $\hat{V}_{\alpha_3}(\infty)$ ("u-channel decomposition"). Considering the s-channel for definiteness, the integration variable $\alpha$ parameterizes the primary operator resulting from the OPE of $\hat{V}_{\alpha_3}$ with $\hat{V}_{\kappa_2 h_1}$. The one-loop contributions $C(m, \alpha)$ are structure constants of the Toda CFT,

\[\text{Let } h_1, \ldots, h_N \text{ denote the weights of the fundamental representation of } A_{N-1}, \text{ which sum to 0. These form an orthonormal basis of the Cartan algebra } \mathfrak{h}, \text{ identified to } \mathfrak{h}^* \text{ by the Killing form defined by } (h_i, h_j) = \delta_{ij} - 1/N. \text{ The highest weight of any representation of } A_{N-1} \text{ can be written } \Omega = n_1 h_1 + \cdots + n_N h_N \text{ with integers } n_1 \geq \cdots \geq n_N = 0. \text{ We also let } \rho = \frac{1}{2} \sum_{i<j} (h_i - h_j) = \sum_{i=1}^{N} \frac{N+1-2i}{2} h_i \text{ be the half-sum of positive roots and } Q = (b + b^{-1}) \rho. \]

\[\text{Moments are elements of } \mathfrak{h}. \text{ Normalizability requires } \alpha - Q \text{ to be an imaginary element of } \mathfrak{h}. \text{ The dimension of } V_\alpha \text{ and other quantum numbers are invariant under Weyl transformations, and it turns out that the Toda CFT has a single operator with a given set of quantum numbers, hence } V_\alpha \text{ itself is invariant up to a scalar. We choose a normalization } \hat{V}_\alpha \text{ invariant under Weyl transformations; the normalization also avoids annoying constants in the AGT relation, and it does not affect conformal blocks nor braiding.} \]

\[\text{Many authors consider semi-degenerate momenta of the form } \alpha = -\lambda h_N. \text{ This choice is mapped to ours by a Weyl reflection: } -\lambda h_N \to (N(b + b^{-1}) - \lambda) h_1. \]

\[\text{More generally, } \alpha = -b\Omega_1 - b^{-1}\Omega_2, \text{ where } \Omega_1 \text{ and } \Omega_2 \text{ are highest weights of two representations of } A_{N-1}, \text{ are fully degenerate and form a discrete set. We will always take } \Omega_2 = 0 \text{ and } \Omega_1 = K h_1, \text{ highest weight of the } K \text{-th symmetric representation of } A_{N-1}. \text{ Both semi-degenerate and fully degenerate primary operators are interesting because there are null-vectors among their } W_N \text{ descendants.} \]
and the (anti)instanton partition functions \( f(m, a, x) \) and \( f(m, a, \bar{x}) \) are (anti)holomorphic s-channel conformal blocks.

Four-point function of \( W_N \) primary operators do not decompose so simply into (anti)holomorphic conformal blocks in general. Inserting a complete set of states (both primaries and their descendants) in a generic four-point function \( \langle V_1 V_2 V_3 V_4 \rangle \) gives schematically \( \int \mathcal{D}a \sum_{f} \langle V_1 V_2 (W_{-f} W_{-f} V_3) (W_{-f} W_{-f} V_4) \rangle \), where \( W_{-f} \) and \( W_{-f} \) are an orthonormal basis of the left/right-moving \( W_N \) algebras and we used \( \langle V_3 V_4 \rangle = 1 \). When each three-point function feature a semi-degenerate vertex operator, its null-vectors can be used to convert the action of \( W \) and \( \bar{W} \) into that of Virasoro generators only, which are known to act as differential operators. For the four-point function (2.9) of interest the s-channel and u-channel have this property (not the t-channel), which guarantees that the contributions from descendants of a given primary operator factorize into conformal blocks.

The s-channel and u-channel decompositions converge in different regions \( |x| \leq 1 \). In both cases, every conformal block is a fractional power of \( x \) multiplied by a power series which converges in the unit disk. They can in fact be analytically continued to the whole plane minus branch cuts joining 0, 1, and \( \infty \). A convenient choice will be to cut along \([0, \infty)\), in other words normalize conformal blocks so that their leading term is a fractional power of \((-x)\). We define the braiding kernel as the integral kernel expressing s-channel blocks in terms of u-channel ones after analytic continuation. This is the Toda CFT translation of the S-duality kernel defined in (2.5). For comparison we write formulas next to each other:

\[
f(m, a, x) = \int \mathcal{D}a' B(m, a, a') f_D(m, a', x_D) \tag{2.11}
\]

\[
\mathcal{F} \left[ \frac{\alpha_3}{\kappa_4 h_1} \frac{\alpha_1}{\alpha} \right] (x) = \int \mathcal{D}a_3 B_{\alpha_1 \alpha_2 \alpha_3} \left[ \frac{\kappa_4 h_1}{\alpha_3} \frac{\kappa_2 h_1}{\alpha_1} \right] \mathcal{F} \left[ \frac{\kappa_2 h_1}{\alpha_3} \frac{\alpha_1}{\alpha_2 \alpha_3} \right] (x) \tag{2.12}
\]

The \( \alpha_{32} \) integral runs over imaginary values for \( \alpha_{32} - Q \). The blocks \( \mathcal{F}(x) \) and \( f(x) \) differ by the same factor \((-x)^{\alpha_0}(1-x)^{\alpha_1}\) in both channels, hence \( B(m, a, a') = B_{\alpha_1 \alpha_2 \alpha_3} \).

In the normalization where the leading term of \( f(x) \) is a power of \( x \), the S-duality kernel is changed by a phase due to altered branch cuts. Using \( x^\lambda = e^{i \pi \lambda}(1-x)^{\lambda} \) with \( \epsilon = \text{sign} \text{Im} \, x \), and given the semi-classical limits \( f(m, a, x) \sim x^{\frac{\lambda}{2} \sum_j a_j^2} \) and \( f(m, a, x) \sim x^{-\frac{\lambda}{2} \sum_j a_j^2} \) as \( x \to 0, \infty \), the S-duality kernel in this normalization is

\[
B'(m, a, a') = e^{i \pi \left( \frac{\lambda}{2} \sum_j a_j^2 + \frac{\lambda}{2} \sum_j a_j^2 \right)} B(m, a, a') \tag{2.13}
\]

We will interpret these phases as a Chern-Simons term on the wall. The braiding kernel receives similar phases.

Our goal is to find the kernel \( B_{\alpha_1 \alpha_2 \alpha_3} \). We determine it in section 3 when \( \kappa_2 h_1 \) is fully degenerate, namely \( \kappa_2 = -K b \) with \( K \geq 0 \) an integer, then generalize to all \( \kappa_2 \) in section 4.

### 2.3 Special functions

Besides the Barnes double-Gamma function \( \Gamma_b = \Gamma_{1/b} \), normalized by \( \Gamma_b(b+b^{-1}) = 1 \), we need the double-Sine function \( S_b(x) = S_{1/b}(x) = \Gamma_b(x)/\Gamma_b(b+b^{-1}-x) = 1/S_0(b+b^{-1}-x) \),
The table shows properties of Barnes functions.

| Function | Shift relation |
|----------|----------------|
| $\Gamma_b$ | poles, finite, $\Gamma_b(x + b)/\Gamma_b(x) = \sqrt{2\pi} e^{1/2}/\Gamma(x)$ |
| $S_b$ | poles, zeros, $S_b(x + b)/S_b(x) = 2\sin(\pi bx)$ |
| $\Upsilon_b$ | zeros, zeros, $\Upsilon_b(x + b)/\Upsilon_b(x) = b^{1-2bx} \gamma(bx)$ |

Table 1. Properties of Barnes functions.

and the Upsilon function $\Upsilon_b(x) = \Upsilon_{1/b}(x) = 1/(\Gamma_b(x)\Gamma_b(b + b^{-1} - x)) = \Upsilon_b(b + b^{-1} - x)$. All are meromorphic in $x$. Their zeros and poles are given in Table 1 together with their shift relations expressed using $\gamma(y) = \Gamma(y)/\Gamma(1 - y)$ and the Euler identity $\Gamma(y)\Gamma(1 - y) = \pi/\sin(\pi y)$. In addition, $S_b(b) = b$.

3 Braiding matrices

We determine here the braiding of Toda CFT\(^{12}\) four-point conformal blocks involving a semi-degenerate operator and a fully degenerate one labelled by the $K$-th symmetric representation $\mathcal{R}(K h_1)$ of $A_{N-1}$. Fusion rules of the fully degenerate operator\(^{13}\) reduce the four-point function to a finite sum (rather than an integral) of holomorphic times antiholomorphic conformal blocks. There are $\dim \mathcal{R}(K h_1) = (N + K - 1)$ terms. Braiding is thus given by square matrices of this size.

We begin in section 3.1 with the fundamental representation, so $\alpha = -bh_1$. In that case, conformal blocks are known to be hypergeometric functions. This was initially obtained by solving the null-vector differential equations for $N = 3$ and writing the natural generalization of these results [53]. Fuchsian techniques provide a proof for all $N$ when $c = N - 1$, namely $b^2 = -1$ [52, Theorem 4.1] (which appeared after version 1 of this paper). We outline a mild variation of their proof that generalizes the result to all $b$, under the assumption that well-known fusion rules are correct. Then, as a preparation for more difficult calculations, we review the braiding matrix for these hypergeometric functions that forms the foundation of our new results.

We do not discuss here the case $\alpha = -bh_1 - \cdots - bh_K$ of antisymmetric representations, treated in collaboration with Gomis in [54]. We conjectured there that conformal blocks are vortex partition functions of 2d $\mathcal{N} = (2, 2)$ SQCD. In appendix A.3 of that paper we computed the braiding matrix of the gauge theory result, then showed using shift relations that it is the correct braiding matrix for conformal blocks. This method fixes braiding matrices hence monodromies, but one would need to adapt the proof from the fundamental case to show that the conformal blocks conjectured from gauge theory are indeed correct.

In section 3.2 we turn to the $K$-th symmetric representation, so $\alpha = -Kbh_1$, starting from a conjecture for conformal blocks as gauge theory vortex partition functions [54].

\(^{12}\)Most results apply to all CFTs with $W_N$ symmetry, but to be fully general would require various multiplicity indices: there may be several primary operators with the same momentum.

\(^{13}\)Fusion rules are typically found using a Coulomb gas representation of Toda CFT correlators. They have only been proven rigorously in representation theory of $W_N$ algebras in the simplest case: the fundamental representation, for $b^2 = -1$ (so as to have a free boson realization) [52].
The hard technical point done in this section is to work out the braiding matrix for these blocks. Later, in section 4.3, we prove a pentagon identity relating braiding matrices for \( K \) and \( K - 1 \), which proves by induction that the gauge-theory braiding matrix is the correct one for \( W_N \) conformal blocks. Again, this approach is not sufficient to prove conjectured expressions of conformal blocks, only their braiding and monodromy behaviour.

### 3.1 Braiding a fundamental degenerate

We focus for now on \( \langle \hat{\mathcal{V}} \hat{\mathcal{V}} \hat{\mathcal{V}} \rangle = \langle \hat{\mathcal{V}}_{\alpha_\infty}(\infty) \hat{\mathcal{V}}_{(\kappa+b)h_1}(1) \hat{\mathcal{V}}_{-bh_1}(x, \bar{x}) \hat{\mathcal{V}}_{\alpha_0}(0) \rangle \), a four-point correlation function with one semi-degenerate momentum \((\kappa+b)h_1\) and a degenerate \(-bh_1\), labelled by the highest weight \( h_1 \) of the fundamental representation of \( A_{N-1} \). The shift by \( b \) in \( \kappa \) simplifies some expressions. Momenta are otherwise generic.

Our discussion relies on two fusion rules [53] which can be obtained for the Toda CFT using the Coulomb gas formalism:

\[
\hat{\mathcal{V}}_{-bh_1} \times \hat{\mathcal{V}}_\alpha = \sum_{i=1}^N [\hat{\mathcal{V}}_{\alpha - bh_i}] \tag{3.1}
\]

\[
\hat{\mathcal{V}}_{-bh_1} \times \hat{\mathcal{V}}_{(\kappa+b)h_1} = [\hat{\mathcal{V}}_{\kappa h_1}] + [\hat{\mathcal{V}}_{(\kappa+b)h_1 - bh_2}] \tag{3.2}
\]

where \([\hat{\mathcal{V}}_{\cdots}]\) denotes contributions from \( W_N \) descendants of a primary operator with the given momentum. As usual in 2d CFT, the four-point function can be expanded in three different channels by taking the OPE of \( \hat{\mathcal{V}}_{-bh_1} \) with any of the three other operators. The fusion rules restrict the internal momentum to \( \alpha_0 - bh_s \) for \( 1 \leq s \leq N \) in the s-channel, \( \alpha_\infty - bh_s \) in the u-channel, and \( \kappa h_1 \) or \((\kappa+b)h_1 - bh_2 \) in the t-channel.

In the s-channel, the four-point function is a sum of \( N \) factorized terms:

\[
\langle \hat{\mathcal{V}} \hat{\mathcal{V}} \hat{\mathcal{V}} \rangle = \sum_{j=1}^N C_j^{(s)} \hat{\mathcal{F}}_j^{(s)}(x) \hat{\mathcal{F}}_j^{(s)}(\bar{x}) \tag{3.3}
\]

\[
C_j^{(s)} = \frac{\langle \hat{\mathcal{V}}_{\alpha_\infty} \hat{\mathcal{V}}_{(\kappa+b)h_1} \hat{\mathcal{V}}_{\alpha_0-bh_j} \hat{\mathcal{V}}_{2Q-\alpha_0+bh_j} \hat{\mathcal{V}}_{-bh_1} \hat{\mathcal{V}}_{\alpha_0} \rangle}{\langle \hat{\mathcal{V}}_{\alpha_0-bh_j} \hat{\mathcal{V}}_{2Q-\alpha_0+bh_j} \rangle} \tag{3.4}
\]

where we have absorbed all of the position dependence in the conformal blocks \( \hat{\mathcal{F}} \). A useful property of conformal blocks is their \( x \to 0 \) expansion

\[
\hat{\mathcal{F}}_j^{(s)}(x) = x^{\Delta(\alpha_0-bh_j)-\Delta(\alpha_0)-\Delta(-bh_1)}(1 + \cdots)
\]

\[
= x^{b(\alpha_0-Q,h_j)+\frac{N-1}{2}(b^2+1)}(1 + \cdots) \tag{3.5}
\]

where \((1 + \cdots)\) is a series in non-negative integer powers of \( x \), and similarly for \( \hat{\mathcal{F}}_j^{(s)}(\bar{x}) \). Because of radial ordering, the functions \( \hat{\mathcal{F}}_j^{(s)} \) are a priori only defined on the unit disk (with a branch point at 0), but since \( \langle \hat{\mathcal{V}} \hat{\mathcal{V}} \hat{\mathcal{V}} \rangle \) is smooth away from 0, 1, and \( \infty \) the functions can be analytically continued to any simply connected domain avoiding these points. Two

---

\(^{14}\)We thank Sylvain Ribault for discussions on this topic. It also seems feasible to use the recent development [52] to prove our conjectured conformal blocks.
natural choices are the complex plane minus cuts on \((-\infty, 0] \cup [1, \infty),\) and the complex plane minus cuts on \([0, 1) \cup [1, \infty).\) We will mostly use the second one.

The u-channel decomposition is similar, and conformal blocks have a simple \(x \to \infty\) expansion in terms of a series \(1 + \cdots\) with non-negative integer powers of \(1/x:\)

\[
\langle \hat{V} \hat{V} \hat{V} \rangle = \sum_{j=1}^{N} C_j^{(u)} F_j^{(u)}(x) F_j^{(u)}(\bar{x})
\]

\[
F_j^{(u)}(x) = x^{\Delta(a_{\infty}) - \Delta(a_{\infty} - bh_1) - \Delta(-bh_1)}(1 + \cdots) = x^{-b(a_{\infty} - Q, h_j) + \frac{N-1}{2}(b^2+1)+ \frac{N-1}{2}b^2}(1 + \cdots). \tag{3.7}
\]

Again, \(F_j^{(u)}(x)\) extends to \(\mathbb{C} \setminus \{0, 1\}\) minus some cuts, for instance along \([0, 1) \cup [1, \infty).\)

The t-channel is more subtle, as it involves three-point functions of \(\hat{V}_{a_{\infty}}, \hat{V}_{a_0},\) and a descendant of the primary \(\hat{V}_{x_1} \) or \(\hat{V}_{(x+b)h_1 \sim bh_2}.\) Contributions from primaries with momentum \(x_1 \) factorize because this momentum is semidegenerate. Contributions from primaries with momentum \((x+b)h_1 \sim bh_2\) do not factorize (except for \(N = 2).\) We deduce

\[
\langle \hat{V} \hat{V} \hat{V} \rangle = C_1^{(t)} F_1^{(t)}(x) F_1^{(t)}(\bar{x}) + C_2^{(t)} F_2^{(t)}(x, \bar{x}) \tag{3.8}
\]

with the following \(x \to 1\) expansions, where \(1 + \cdots\) denote series in non-negative integer powers of \((1 - x)\) and \((1 - \bar{x}),\)

\[
F_1^{(t)}(x, \bar{x}) = |1 - x|^{[2(\Delta(xh_1) - \Delta((x+b)h_1) - \Delta(-bh_1))}(1 + \cdots) = |1 - x|^{2b(x+b)(N-1)/N}(1 + \cdots) \tag{3.9}
\]

\[
F_2^{(t)}(x, \bar{x}) = |1 - x|^{[2(\Delta((x+b)h_1-bh_2) - \Delta((x+b)h_1) - \Delta(-bh_1))}(1 + \cdots) = |1 - x|^{2[-b(x+b)/N+b^2+1]}(1 + \cdots). \tag{3.10}
\]

### 3.1.1 Monodromy matrices

Away from the cuts, the equality \(\sum_j C_j^{(s)} F_j^{(s)} = \sum_j C_j^{(u)} F_j^{(u)}\) implies that the sets \(\{F_j^{(s)}\}\) and \(\{F_k^{(u)}\}\) are different bases of an \(N\)-dimensional space of holomorphic functions. The change of basis matrix is called the braiding matrix. Similarly \(F_2^{(t)}\) is (non-canonically) a sum of \(N\) \(1\) factorized terms, and their \(N\) \(1\) holomorphic factors together with \(F_1^{(t)}\) form another basis of the same space.

The expansions of conformal blocks at \(0, 1,\) and \(\infty\) above imply certain monodromy properties when analytically continuing the functions through cuts. The monodromy \(M_{(0)}\) around \(x = 0\) is diagonal in the basis \(F^{(s)}\) and eigenvalues can be read off from the expansion (3.5). While the monodromies \(M_{(1)}\) and \(M_{(\infty)}\) are non-diagonal \(N \times N\) matrices in this \(s\)-channel basis, they are diagonalizable (by going to the \(t\)- or \(u\)-channel bases) and their eigenvalues can be read off from the expansions above. Namely, eigenvalues of the monodromy \(M_{(1)}\) around \(x = 1\) are seen from (3.9) and (3.10), the second one having multiplicity \(N - 1\), and the monodromy \(M_{(\infty)}\) has \(N\) eigenvalues known from (3.7). Finally, \(M_{(\infty)} = M_{(1)} M_{(0)}\) since \(x \in \{0, 1, \infty\}\) are the only singular points.
We thus have a triplet of invertible diagonalizable $N \times N$ matrices $M(0)$, $M(1)$ and $M(\infty)$ obeying $M(\infty) = M(1)M(0)$ and with prescribed eigenvalues, such that $M(1)$ has eigenvalues $y_1$ with multiplicity 1 and $y_2$ with multiplicity $N - 1$ while eigenvalues of $M(0)$ and $M(\infty)$ have no multiplicity. We now show that such a triplet is unique up to conjugation. Choose a basis where $M(0)$ is diagonal. Since $M(1) - y_2$ has rank 1 it can be written as $M(1)_{ij} = y_2 \delta_{ij} + (y_1 - y_2)v_iv_j$ for some vectors $v$ and $w$. By rescaling the $i$-th basis vector by $\sqrt{v_i/w_i}$ and setting $u_i = \sqrt{v_i/w_i}$ we get a basis in which $M(0) = \text{diag}(x_1, \ldots, x_N)$ is still diagonal and

$$M(1)_{ij} = y_2 \delta_{ij} + (y_1 - y_2)u_iu_j. \quad (3.11)$$

Denote eigenvalues of $M(\infty)$ as $z_i$. Compute the determinant of $M(1) - y_2x_pM^{-1}(0)$ for some $p$. On the one hand the matrix is the sum of a diagonal matrix $y_2(1 - x_pM^{-1}(0))$ with $p$-th entry 0 and a rank 1 matrix so subtracting the $p$-th row then the $p$-th column from others makes it diagonal. On the other hand the matrix is equal to $(M(\infty) - y_2x_p)M^{-1}(0)$. We get

$$\det(M(1) - y_2x_pM^{-1}(0)) = (y_1 - y_2)y_p^2 \prod_{s \neq p}^N (y_2(1 - x_px_s^{-1})) \quad (3.12)$$

$$= \det(M(\infty) - y_2x_p)\det(M(0))^{-1} = \prod_{s=1}^N \frac{z_s - y_2x_p}{x_s}. \quad (3.13)$$

Therefore,

$$u_p^2 = \frac{\prod_{s=1}^N (z_s - y_2x_p)}{y_p^{N-1}(y_1 - y_2)x_p \prod_{s \neq p}(x_s - x_p)}. \quad (3.14)$$

This fixes components of $u$ up to signs, which can be absorbed in a choice of basis, hence it fixes $M(1)$ and concludes this straightforward proof of uniqueness.

Armed with this set of monodromy matrices we should ask whether they fix conformal blocks uniquely. The answer is no, of course, as multiplying conformal blocks by a meromorphic function does not change their monodromy. However, we can use more information: the four-point function should only be singular at $z \in \{0, 1, \infty\}$ so conformal blocks must be holomorphic (with branch cuts) away from these points.

### 3.1.2 Explicit conformal blocks (proof)

The s-channel conformal blocks proposed in [53] are

$$F_{F,FL}^+(x) = \sum (\alpha_0 - Qh_j)^{a_1}\cdots\sum (\alpha_N - Qh_j)^{a_N}\left(1 - b(x+b)/N \right)^{k=1-b(x+b)/N} F_{N-1} \left( 1 - b(x+b)/N \right), \quad (3.15)$$

where the hypergeometric function $F_{N-1}$ is defined in terms of Pochhammer symbols

$$F_{N-1} \left( a_1, \ldots, a_N \mid b_1, \ldots, b_{N-1} \right) = \sum_{k \geq 0} \frac{x^k (a_1)_k \cdots (a_N)_k}{k! (b_1)_k \cdots (b_{N-1})_k}. \quad (3.16)$$
They have the correct leading behaviour (3.5) near $x = 0$, hence the correct monodromies $M_{(0)}^{FL} = M_{(0)}$. As we review in section 3.1.3 their analytic continuations close to $x = 1$ and $x = \infty$ are known [55] and involve the correct powers of $1 - x$ and of $1/x$, respectively, which means that the monodromy matrices have the correct eigenvalues. Given our uniqueness proof above, all three monodromy matrices (expressed for instance in the $s$-channel basis) are correct.

Using Fuchsian techniques inspired by [52], let us now deduce that the proposed blocks (3.15) are indeed the correct conformal blocks.\footnote{Our argument in version 1 was flawed: treating conformal blocks all together as in [52] is essential. The only assumption in the proof we give now is that the well-known fusion rules (3.1) and (3.2) hold.} Hypergeometric functions famously obey a differential equation, and in fact the $N$ functions $F_j^{(s)}$ are linearly-independent solutions to the same $N$-th order Fuchsian differential equation in $x$, regular except for singularities at 0, 1 and $\infty$. Thus, the solutions have Wronskian $\det \Phi \neq 0$ away from these singularities, where\footnote{Note that each column of the analogue of $\Phi$ in [52] is a collection of blocks for a given value of $\alpha_\infty$. We could have done the same, with $\alpha_\infty = \alpha - h_m/b$ for the $m$-th column where $\alpha$ is some fixed momentum.}

$$
\Phi = \begin{pmatrix}
F_1^{(s),FL} & \partial_x F_1^{(s),FL} & \ldots & \partial_x^{-1} F_1^{(s),FL} \\
\vdots & \vdots & & \vdots \\
F_N^{(s),FL} & \partial_x F_N^{(s),FL} & \ldots & \partial_x^{-1} F_N^{(s),FL}
\end{pmatrix}.
$$

Each of the columns has the same monodromy matrices $M_{(0)}$, $M_{(1)}$, $M_{(\infty)}$ as the real conformal blocks $F_j^{(s)}$. Now consider the vector $\Phi^{-1}(F_1^{(s)}, \ldots, F_N^{(s)})^T$. It is holomorphic away from $x = 0$, $x = 1$, $x = \infty$ because $\Phi$ is invertible, and it has no monodromy around these three points because the monodromy matrices cancel. Expanding near $x = 0$, the non-integer powers $x^{-\beta_j}$ with $\beta_j = -b(\alpha_0 - Q, h_j) - \frac{N-1}{2}(b^2 + 1)$ cancel and we find

$$
\Phi^{-1}(F_1^{(s)}, \ldots, F_N^{(s)})^T = \begin{pmatrix}
(1 + O(x)) & \frac{-\beta_1}{x}(1 + O(x)) & \ldots & \frac{(-\beta_1)_{N-1}}{x^{N-1}}(1 + O(x)) \\
\vdots & \vdots & & \vdots \\
(1 + O(x)) & \frac{-\beta_N}{x}(1 + O(x)) & \ldots & \frac{(-\beta_N)_{N-1}}{x^{N-1}}(1 + O(x))
\end{pmatrix}^{-1} \begin{pmatrix}
1 + O(x) \\
\vdots \\
1 + O(x)
\end{pmatrix}
$$

$$
= \begin{pmatrix}
1 & 0 & \cdots & 0 \\
0 & x & \cdots & 0 \\
\vdots & \ddots & \ddots & \vdots \\
0 & \cdots & 0 & x^{N-1}
\end{pmatrix} \begin{pmatrix}
1 & -\beta_1 & \ldots & (-\beta_1)_{N-1} \\
\vdots & \vdots & & \vdots \\
1 & -\beta_N & \ldots & (-\beta_N)_{N-1}
\end{pmatrix}^{-1} \begin{pmatrix}
1 + O(x) \\
\vdots \\
1 + O(x)
\end{pmatrix} = \begin{pmatrix}
1 \\
0 \\
\vdots \\
0
\end{pmatrix} + O(x).
$$

The expansion near 1 (resp. $\infty$) works similarly: the columns with derivatives involve different powers of $1 - x$ (resp. $1/x$) but this can be factored, leaving a finite result that tends to the column vector $(1, 0, \ldots, 0)^T$.

Altogether we have a vector whose components are holomorphic on the whole Riemann sphere, hence are constant. We know its value at $x = 0$ from (3.18) and deduce that the true conformal blocks are equal to the first column of $\Phi$, namely the expression found in [53].
3.1.3 Braiding matrices

Let \( f_j^{(s)} \) denote the hypergeometric function in (3.15). We now derive the braiding matrix for the functions \((-x)^{j(\alpha - Q, h)} f_j^{(s)}(x)\), then convert it to the braiding matrix (3.24) for the blocks \( F \) by introducing phases.

To compute their braiding matrix it is convenient to introduce notations. Let \( i \mu_p \) and \( i \tilde{\mu}_p \) be \( 2N \) complex numbers such that

\[
\alpha_0 = Q - \frac{1}{b} \sum_{p=1}^{N} i \mu_p h_p, \quad \alpha_\infty = Q - \frac{1}{b} \sum_{p=1}^{N} i \tilde{\mu}_p h_p, \quad \kappa = \frac{1}{b} \sum_{p=1}^{N} (1 + i \mu_p + i \tilde{\mu}_p). \tag{3.19}
\]

This parametrization is redundant under shifts of all \( i \mu_p \) and \( -i \tilde{\mu}_p \). The s-channel factor \((-x)^{-i \mu_p} f_j^{(s)}(x)\) can be expressed as the Mellin-Barnes integral given below, which converges away from the positive real axis. For \( |x| \leq 1 \) we can close the contour integral towards \( v \to \pm \infty \), and enclose either the poles at \( v + i \mu_j \in \mathbb{Z}_{\geq 0} \) or the \( N \) families of poles at \( v - i \tilde{\mu}_k \in \mathbb{Z}_{\leq 0} \) labelled by \( 1 \leq k \leq N \). The first choice yields a single s-channel factor, while the second yields a sum of \( N \) u-channel factors:

\[
(-x)^{-i \mu_p} f_j^{(s)}(x) = \text{cont} D_j \int_{-\infty}^{\infty} \frac{dv}{2\pi i} \prod_{k=1}^{N} \frac{\Gamma(-i \tilde{\mu}_k + v)}{\Gamma(1 + im_k + v) \Gamma(-im_j)(-x)^v} \tag{3.20}
\]

\[
= \sum_{k=1}^{N} D_j \hat{B}^{0} \hat{D}_k (-x)^{i \tilde{\mu}_k} f_k^{(u)}(x). \tag{3.21}
\]

We will not need the explicit expression for \( f_k^{(u)} \), which are hypergeometric series 1 + \cdots in non-positive integer powers of \( x \). The coefficients \( D, \hat{B}^{0} \) and \( \hat{D} \) are given by

\[
\hat{B}^{\epsilon}_{jk} = \frac{\pi e^{\pi \epsilon (\mu_j + \tilde{\mu}_k)}}{\sin \pi (-i \tilde{\mu}_k - \mu_j)}
\]

\[
D_j = \prod_{t=1}^{N} \frac{\Gamma(1 + im_t - im_j)}{\Gamma(-im_t - im_j)} \quad \hat{D}_k = \prod_{t=1}^{N} \frac{\Gamma(-im_t + im_k)}{\Gamma(1 + im_t + im_k)}. \tag{3.22}
\]

Here we have included a parameter \( \epsilon \in \{0, \pm 1\} \). It is sometimes convenient to consider s-channel factors \( x^{-i \mu_p} f_j^{(s)}(x) \) analytically continued with branch cuts on \((-\infty, 0] \cup [1, +\infty)\), and u-channel factors \( x^{i \tilde{\mu}_k} f_k^{(u)}(x) \) with branch cuts along \((-\infty, 0] \cup [0, 1]\). Using \((-x)^\lambda = e^{-i \pi \epsilon \lambda x^\lambda} \) for \( \epsilon = \text{sign}(\text{Im} \ x) \), we obtain

\[
x^{-i \mu_p} f_j^{(s)}(x) = \sum_{k=1}^{N} D_j \hat{B}^{\epsilon}_{jk} \hat{D}_k x^{i \tilde{\mu}_k} f_k^{(u)}(x). \tag{3.23}
\]
The braiding matrix in $F_j^{(s)}(x) = \sum_{k=1}^{N} \mathcal{B}_{jk}^{e} F_k^{(u)}(x)$ includes a phase: explicitly we get
\[
\mathcal{B}_{jk}^{e} \left[ \frac{(x + b)h_1 - bh_1}{\alpha_\infty} \right] = e^{i \pi e[b(x+b)/N - b^2 - 1]} D_j \mathcal{B}_{jk}^{e} \mathcal{B}_{k}^{e} = \prod_{l \neq j}^{N} \Gamma(1 + b(Q - \alpha_0, h_l - h_{j})) \prod_{l = 1}^{N} \Gamma(1 - \frac{b}{N} - b(Q - \alpha_0, h_l) - b(Q - \alpha_\infty, h_{u})) \times \sin \pi(1 - \frac{b}{N} - b(Q - \alpha_0, h_l) - b(Q - \alpha_\infty, h_{k})) \prod_{u \neq k}^{N} \Gamma(b(Q - \alpha_\infty, h_k - h_{u})) \prod_{i = 1}^{N} \Gamma(\frac{b}{N} + b(Q - \alpha_0, h_i) + b(Q - \alpha_\infty, h_{k})).
\]

The s-channel blocks $F_j^{(s)}(x)$ have the expected power of $x$ (hence the expected monodromies) around 0. The eigenvalues of the monodromy $M_{(s)}$ around 0 are also correct, as can be checked by combining the u-channel factors in (3.21) with the additional powers of $x$ and $1 - x$ in (3.15) and comparing to the u-channel asymptotics (3.7) expected from CFT. Finally, from the braiding matrix above we deduce the monodromy $M_{(1)} = \mathcal{B}^+(\mathcal{B}^-)^{-1}$ around 0. All components $\mathcal{B}_{jk}^\pm - \mathcal{B}_{jk}^\mp = 2\pi i$ are equal hence $\mathcal{B}^+ - \mathcal{B}^-$ has rank 1, and $e^{-2\pi i \gamma_1} M_{(1)} - 1 = D(\mathcal{B}^+ + \mathcal{B}^-)\mathcal{B}^-)^{-1}$ too. Therefore, $M_{(1)}$ has the eigenvalue $e^{2\pi i \gamma_1}$ with multiplicity $N - 1$. Its last eigenvalue is fixed by $\text{det} e^{-2\pi i \gamma_1} M_{(1)} = \text{det} \mathcal{B}^+ / \text{det} \mathcal{B}^-$.

These eigenvalues coincide with those expected of t-channel blocks. In fact the precise exponents of $(1 - x)$ also match [55]. We used this in our proof that conformal blocks are given by the explicit hypergeometric formula (3.15).

3.2 Braiding a symmetric degenerate

We now generalize the discussion above to a degenerate vertex operator $\hat{V}_{-Kb h_1}$ labelled by the K-th symmetric representation $\mathcal{R}(Kh_1)$ of $A_{N-1}$. Namely we consider its four-point function with two generic operators $\hat{V}_{\alpha_\infty}$ and $\hat{V}_{\alpha_0}$ and one semi-degenerate $\hat{V}_{(x+Kb)h_1}$, including a shift by $Kb$ for later convenience. The braiding (3.42) we find is new. Contrarily to the $K = 1$ case of the previous section which we reuse throughout the paper, the $K > 1$ case is only used to find the correct generalization to continuous values of $K$ in section 4.

Explicit s-channel and u-channel decompositions and their conformal blocks were conjectured in [54, appendix A.5], thanks to a relation with sphere partition functions of 2d $\mathcal{N} = (2, 2)$ gauge theories. We use the same notations $im_p$ and $i\tilde{m}_p$ as in (3.19) (ambiguous under overall shifts of all $im_p$ and $-i\tilde{m}_p$, namely $\alpha_0 = Q - \frac{1}{b} \sum_{p=1}^{N} im_p h_p$ and $\alpha_\infty = Q - \frac{1}{b} \sum_{p=1}^{N} i\tilde{m}_p h_p$ and $\alpha_\infty = \frac{1}{b} \sum_{p=1}^{N} (1 + im_p + i\tilde{m}_p)$. The four-point function is a sum over weights $h_{[n]} = \sum_{s=1}^{N} n_s h_s$ of the symmetric representation $\mathcal{R}(Kh_1)$: up to a constant $C$,
\[
\langle \hat{V}_{\alpha_\infty}^{(s)}(x) \hat{V}_{(x+Kb)h_1}^{(1)}(1) \hat{V}_{-Kb h_1}(x, \bar{x}) \hat{V}_{\alpha_0}^{(0)}(0) \rangle = C \sum_{n_1 + \cdots + n_N = K} \prod_{(s, \mu)}^{N} \prod_{l = 1}^{N} \gamma(\frac{im_{s\mu} - im_{t
u}}{1 + i\tilde{m}_t + im_{s\mu}}) F_{[n]}^{(s)}(x) F_{[n]}^{(s)}(\bar{x}),
\]

(3.25)
where \( \gamma(y) = \Gamma(y)/\Gamma(1-y) \) and we introduced the notations
\[
\prod_{(s,\mu)}^{[n]} \equiv \prod_{s=1}^{N} \prod_{\mu=0}^{n_s-1} \quad \text{and} \quad \text{im}_{s\mu} = \text{im}_s + \mu b^2. \tag{3.26}
\]

The conformal blocks \( F_{[n]}^{(s)} \) are
\[
F_{[n]}^{(s)}(x) = (1 - x)^{-\gamma_1} x^{-\gamma_0 - \sum_{(s,\mu)}^{[n]} \text{im}_{s\mu} f_{[n]}^{(s)}(x)}
\]
\[
\gamma_0 = -\frac{K(K - 1)}{2} b^2 - \frac{K(N - 1)}{2} (b^2 + 1) - \frac{K}{N} \sum_{s=1}^{N} \text{im}_s \tag{3.27}
\]
\[
\gamma_1 = -\frac{K(N - K)}{N} b^2 + \frac{K}{N} \sum_{s=1}^{N} (\text{im}_s + i\tilde{m}_s) \tag{3.28}
\]
\[
f_{[n]}^{(s)}(x) = \sum_{k \geq 0}^{[n]} \prod_{(s,\mu)}^{[k]} \left. x^{k_{sn}} \prod_{t=1}^{N} \frac{(-i\tilde{m}_t - \text{im}_{st})_{k_{st}}}{(1 + i\text{im}_{tn} - \text{im}_{st})_{k_{st}}} \right|_{k=1} \tag{3.29}
\]
\[
\times \frac{\prod_{i=1}^{N} (1 + i\text{im}_{tn} - \text{im}_{st} + k_{st} - k_{(nt-1)} k_{(nt-1)})}{\prod_{i=1}^{N} (1 + i\text{im}_{tn} - \text{im}_{st} + k_{st} - k_{nt} k_{nt-1})} \right). \tag{3.30}
\]

For a given weight \( h_{[n]} \) of \( R(Kh_1) \), and a choice of \( 1 \leq p \leq N \) we consider the following generalization of the Mellin-Barnes integral (3.21) used for \( K = 1 \).
\[
P_{[n]}^p = \frac{\Gamma(-b^2)K}{K!} \prod_{j=1}^{K} \left. \int_{-\infty}^{\infty} d\sigma_j \right|_{\sigma_j=0} \frac{\prod_{i \neq j}^{K} \Gamma(i\sigma_i - i\sigma_j - b^2)}{\Gamma(i\sigma_i - i\sigma_j)} \tag{3.31}
\]
\[
\times \prod_{j=1}^{K} (-x)^{i\sigma_j} \prod_{s=1}^{N} \frac{\Gamma(-i\text{im}_s + \text{is}_{s\mu}) \Gamma(-i\text{im}_s - \text{is}_{s\mu})}{\Gamma(1 + i\text{im}_{st} + i\sigma_j) \Gamma(1 + i\text{im}_{st} - i\sigma_j)} \right|_{\text{im}_{st}=0}.
\]

The contours lie between poles of all the \( \Gamma(-i\text{im}_s + i\sigma_j) \) and poles of all the \( \Gamma(-i\text{im}_s - i\sigma_j) \). The integral converges for \( x \not\in [0, \infty) \) because there are fewer \( \Gamma \) functions in the denominator.

For \( |x| \leq 1 \) we can close contours towards \( i\sigma_j \rightarrow \mp i\infty \), enclosing some poles. Start with \( |x| < 1 \). If the partition \( [n] \) has a single non-zero entry (e.g., if \( K = 1 \)) we can choose \( p \) so that \( n_s = 0 \) for \( s \neq p \), and then all numerators \( \Gamma(-i\text{im}_s - i\sigma_j) \) cancel with denominators except for \( s = p \). But in general there is no such cancellation and the integral gives a linear combination of s-channel factors (3.30); our whole work will be to disentangle this sum:
\[
P_{[n]}^p = \sum_{[k]} T_{[n][k]}^p (-x)^{\sum_{(s,\mu)}^{[k]} \text{im}_{s\mu} f_{[k]}^{(s)}}, \tag{3.32}
\]
\[
T_{[n][k]}^p = \prod_{(s,\mu)}^{[k]} \prod_{t=1}^{N} \frac{\Gamma(-i\text{im}_t - \text{im}_{st}) \Gamma(\text{im}_{st} - \text{im}_{tk})}{\Gamma(1 + i\text{im}_{tn} - i\text{im}_{st} \Gamma(\text{im}_{st} - i\text{im}_{tn})}. \tag{3.33}
\]

The sum ranges over weights of \( R(Kh_1) \), but the matrix \( T^p \) is “triangular” in the sense that its component \( T_{[n][k]}^p \) vanishes if \( n_s < k_s \) for any \( s \neq p \).
Closing contours towards $\sigma_j \to \infty$ for $|x| > 1$ gives a sum of u-channel factors
\begin{equation}
P^p_{[n]} = \sum_{[n]} \frac{U^p_{[n][n]}(-x) \Sigma^{[n]}_{(s, \mu)} \tilde{m}_{s \mu} f^{(u)}_{[n]}}{[n]} \tag{3.34}
\end{equation}

\begin{equation}
U^p_{[n][n]} = \prod_{(s, \mu), t \neq p}^{N} \prod_{t = 1}^{N} \Gamma(\tilde{m}_{s \mu} - \tilde{m}_{t \mu}) \Gamma(-\tilde{m}_{s \mu} - \tilde{m}_{t \mu}) \tag{3.35}
\end{equation}

This leads to the braiding
\begin{equation}
(-x)^{-\sum_{(s, \mu)}^{[n]} \tilde{m}_{s \mu} f^{(u)}_{[n]}} = \sum_{[n]} \left( (T^p)^{-1} U^p \right)_{[n][n]} (-x) \Sigma^{[n]}_{(s, \mu)} \tilde{m}_{s \mu} f^{(u)}_{[n]} \tag{3.36}
\end{equation}

We thus need to invert the matrix $T^p$ then multiply the result by $U^p$. A consistency check is that the braiding matrix $(T^p)^{-1} U^p$ must not depend on $p$.

Split $T^p = \tilde{T}^p D^p$ with $D^p$ diagonal:
\begin{equation}
\tilde{T}^p_{[n][k]} = \prod_{(s, \mu), t \neq p}^{N} \prod_{t = 1}^{N} \frac{1}{\pi} \sin \pi (\tilde{m}_{s \mu} - \tilde{m}_{t \mu}) \tag{3.37}
\end{equation}

\begin{equation}
D^p_{[k][l]} = \delta_{[k][l]} \prod_{(s, \mu), t \neq p}^{N} \prod_{t = 1}^{N} \Gamma(-\tilde{m}_{t \mu} - \tilde{m}_{s \mu}) \Gamma(\tilde{m}_{s \mu} - \tilde{m}_{t \mu}) \tag{3.38}
\end{equation}

A proposal for $(\tilde{T}^p)^{-1}$ is found by trial and error:
\begin{equation}
(\tilde{T}^p)^{-1}_{[n][k]} = \begin{cases} 
0 & \text{if } n_t < k_t \text{ for any } t \neq p, \text{ and otherwise } \\
\prod_{s < t}^{N} \prod_{(s, \mu), t \neq p}^{N} & \frac{1}{\pi} \sin \pi (\tilde{m}_{s \mu} - \tilde{m}_{t \mu}) \sin \pi (\tilde{m}_{t \mu} - \tilde{m}_{s \mu}) 
\end{cases} \tag{3.39}
\end{equation}

We must prove that $\sum_{[k]}((\tilde{T}^p)^{-1})_{[n][k]}(\tilde{T}^p)_{[k][j]} = \delta_{[n][j]}$. Since both matrices are “triangular” their product is as well. It is straightforward to compute the diagonal coefficients $((\tilde{T}^p)^{-1} T^p)_{[n][n]} = (\tilde{T}^p)^{-1}_{[n][n]} T^p_{[n][n]} = 1$. There remains to show that coefficients $[n][j]$ with $j_s \leq n_s$ for all $s \neq p$, and with $[j] \neq [n]$ (equivalently $j_p > n_p$) vanish. Cancelling factors of $\frac{1}{\pi} \sin \pi (\ldots)$ as much as possible yields
\begin{equation}
\sum_{[k]}((\tilde{T}^p)^{-1})_{[n][k]}(\tilde{T}^p)_{[k][j]} = \prod_{j_s \leq n_s \forall s \neq p}^{N} \prod_{1 \leq s < t \leq N} \frac{1}{\pi} \sin \pi (\tilde{m}_{s \mu} - \tilde{m}_{t \mu}) \frac{1}{\pi} \sin \pi (\tilde{m}_{t \mu} - \tilde{m}_{s \mu}) \tag{3.40}
\end{equation}

\begin{equation}
\times \prod_{t \neq p}^{N} \frac{1}{\pi} \sin \pi (\tilde{m}_{p \mu} - \tilde{m}_{t \mu}) \prod_{n_p = n_p + 1}^{N} \frac{1}{\pi} \sin \pi (\tilde{m}_{p \mu} - \tilde{m}_{k \mu}) \prod_{t \neq p, j_s \leq n_s \forall s \neq p}^{N} \frac{1}{\pi} \sin \pi (\tilde{m}_{s \mu} - \tilde{m}_{t \mu}).
\end{equation}
This is the sum of residues of
\[ \prod_{s,t}^{N} \left[ \frac{1}{\pi} \sin \pi (i \tau_t - i \tau_s) \right] \frac{1}{\pi} \sin \pi (im_{m_{i1}} - im_{m_{s1}}) \]
\[ \times \prod_{t \neq p}^{N} \frac{1}{\pi} \sin \pi (im_{m_{p1}} - im_{m_{t1}}) \prod_{\mu=n_p+1}^{j_p-1} \frac{1}{\pi} \sin \pi (im_{m_{\mu}} + i \tau_t) \]
\[ \prod_{s,t}^{N} \prod_{\mu=j_s}^{n_s} \frac{1}{\pi} \sin \pi (im_{m_{\mu}} + i \tau_t) \]
\[ \text{at } i \tau_t = -im_{t,k_t}. \]
Each \( i \tau_t \) appears in \( N - 2 + j_p - n_p - 1 \) sines in the numerator, and \( \sum_{s \neq p} (1 + n_s - j_s) = N - 1 + j_p - n_p \) in the denominator, in other words, two more. Thus the function is 1-periodic in each variable \( i \tau_t \), and decays exponentially as \( i \tau_t \to \pm \infty \). The sum of residues thus vanishes, because it is the sum of all residues in a fundamental domain of the periodicity, and there is no contribution from infinity. This establishes (3.39).

The braiding matrix (3.36) is then \( B = (T^p)^{-1} U^p = (D^p)^{-1} (T^p)^{-1} U^p \). The result is a sum of residues of some function of \( N - 1 \) variables \( \tau_t \) for \( t \neq p \). Relabelling the variables \( \tau_t \) using a permutation of \([1, N]\) so that they are numbered from 1 to \( N - 1 \) and \( \phi(N) = p \), we obtain (recall the notations (3.19) and (3.26))
\[ \frac{1}{\pi} \sin \pi (im_{m_{i1}} - im_{m_{s1}}) \prod_{t \neq p}^{N} \frac{1}{\pi} \sin \pi (im_{m_{p1}} - im_{m_{t1}}) \prod_{\mu=n_p+1}^{j_p-1} \frac{1}{\pi} \sin \pi (im_{m_{\mu}} + i \tau_t) \]
\[ \prod_{s,t}^{N} \prod_{\mu=j_s}^{n_s} \frac{1}{\pi} \sin \pi (im_{m_{\mu}} + i \tau_t) \]
\[ (3.41) \]
\[ \text{where } (-1)^\phi \text{ is the signature of } \phi. \text{ This expression does not change if we replace } \phi \text{ by another permutation such that } \phi(N) = p \text{ and we permute the } \tau_j \text{ accordingly: indeed, the sign coming from } \sin \pi (i \tau_j - i \tau_i) \text{ is compensated by the change in } (-1)^\phi. \]

Let us show that \( B^\phi \) does not depend on the arbitrary choice of \( p \), neither does \( \phi \) itself. Choose an index \( 1 \leq j \leq N - 1 \). The variable \( \tau_j \) appears in \( N - 2 + K \) sines in the numerator and \( N + K \) sines in the denominator of (3.42). We thus have \( i \tau_j \to i \tau_j + 1 \) periodicity and no residue at infinity, hence the sum of residues at \( i \tau_j = -im_{\phi(i)k_j} \) is equal to minus the sum of all other residues in a strip of width 1. This yields a sum over \( i \tau_j = -im_{\phi(i)k} \) for all \( 1 \leq i \leq N \) with \( i \neq j \) and \( 0 \leq k \leq n_{\phi(i)} \). The contribution from a given \( i \) with \( i < N \) (and \( i \neq j \)) vanishes by antisymmetry under the exchange \( \tau_i \leftrightarrow \tau_j \), thus only the poles at \( -im_{\phi(N)k} = -im_{pk} \) contribute. All in all, we obtain the same expression as (3.42), with \( \phi(j) \) and \( \phi(N) \) exchanged. The sign coming from flipping the contour is absorbed into a change of the signature \( (-1)^\phi \).

As for \( K = 1 \), the braiding matrix for \( F_{[n]}^{(s)}(x) \) is obtained by including a phase \( e^{i \pi \tau_1} \), and another phase comes from using factors \( x^\tau \) instead of \( (-x)^\tau \). Putting everything together yields
\[ \frac{1}{\pi} \sin \pi (im_{m_{i1}} - im_{m_{s1}}) \prod_{t \neq p}^{N} \frac{1}{\pi} \sin \pi (im_{m_{p1}} - im_{m_{t1}}) \prod_{\mu=n_p+1}^{j_p-1} \frac{1}{\pi} \sin \pi (im_{m_{\mu}} + i \tau_t) \]
\[ \prod_{s,t}^{N} \prod_{\mu=j_s}^{n_s} \frac{1}{\pi} \sin \pi (im_{m_{\mu}} + i \tau_t) \]
\[ (3.42) \]
\[ \text{where } \phi \text{ is independent of } \phi \text{ and } p \text{ and we permute the } \tau_j \text{ accordingly: indeed, the sign coming from } \sin \pi (i \tau_j - i \tau_i) \text{ is compensated by the change in } (-1)^\phi. \]
The explicit expression of $B^\phi$ involves a permutation $\phi$, but is independent of it. To translate this expression explicitly back from the \{im, i\bar{m}\} notation (3.19) to momenta, replace
\[
\text{im}_{su} = b(Q - \alpha_0, h_s) + \mu b^2 + \frac{1}{N} \sum_{t=1}^{N} \text{im}_t \]
\[
\text{i\bar{m}}_{su} = \frac{b}{N} + b(Q - \alpha_\infty, h_s) + \mu b^2 - 1 - \frac{1}{N} \sum_{t=1}^{N} \text{im}_t
\]
then shift the variables $i_j$ to absorb $\frac{1}{N} \sum_{t=1}^{N} \text{im}_t$.

Note that the starting point of this calculation, namely the explicit expression (3.25) for the four-point function, is not proven. However, we prove a shift relation in section 4 for a generalization of the braiding (3.42). This relation expresses in particular the braiding for a given $\hat{V}_{-Kbh_1}$ in terms of that for $\hat{V}_{-(K-1)bh_1}$ and the braiding and fusion for $\hat{V}_{-bh_1}$. By induction on $K$ this proves that the braiding matrix given here is correct.

4 Braiding kernel

Section 4.1 conjectures the braiding kernel (4.4) of two semi-degenerate vertex operators, which generalizes the braiding/fusion kernel for Virasoro ($N = 2$) conformal blocks [44, 45]. We explain in section 4.2 how it reduces to the braiding matrix (3.42) and in section 4.3 that it obeys a very constraining shift relation deduced from a Moore-Seiberg pentagon identity. Discrete symmetries are investigated later in section 5.3.

4.1 Main formula

The four-point function with two generic momenta $\alpha_1$, $\alpha_3$ and two semi-degenerate momenta $\alpha_2 = \kappa_2 h_1$, $\alpha_4 = \kappa_4 h_1$ has an s-channel decomposition
\[
\langle \hat{V}_{\alpha_3}(\infty)\hat{V}_{\kappa_4 h_1}(1)\hat{V}_{\kappa_2 h_1}(x, \bar{x})\hat{V}_{\alpha_1}(0) \rangle = \int d\alpha_{12} \frac{\hat{C}(\alpha_3, \kappa_4 h_1, 2Q - \alpha_{12})\hat{C}(\alpha_{12}, \kappa_2 h_1, \alpha_1)}{\langle \hat{V}_{2Q-\alpha_{12}}\hat{V}_{\alpha_{12}} \rangle} \mathcal{F} \left[ \begin{array}{ccc} \kappa_2 h_1 \\ \kappa_4 h_1 \\ \alpha_1 \end{array} \right] \mathcal{F} \left[ \begin{array}{ccc} \alpha_3 \\ \alpha_{12} \\ \kappa_2 h_1 \end{array} \right] (x)^2
\]
where the denominator is non-zero because of our Weyl-invariant choice of normalization of vertex operators, and $|\cdots|^2$ involves conjugating $x$ but not momenta. Note that the internal momentum $\alpha_{12}$ is continuous rather than discrete because there is no fully degenerate vertex operator. The s-channel conformal blocks are in principle fixed by $W_N$ symmetry. In practice, closed forms are only known thanks to the AGT relation with instanton partition functions, and we will not need them. In this section we again normalize conformal blocks as $\mathcal{F}_{a_{12}}^{(s)}(x) = (-x)^{\Delta(\alpha_{12}) - \Delta(\alpha_1) - \Delta(\kappa_2 h_1)}(1 + \cdots)$: the use of $-x$ instead of $x$ avoids phases.

The u-channel counterpart of (4.1) has $\kappa_2 \leftrightarrow \kappa_4$:
\[
\langle \hat{V}_{\alpha_3}(\infty)\hat{V}_{\kappa_4 h_1}(1)\hat{V}_{\kappa_2 h_1}(x, \bar{x})\hat{V}_{\alpha_1}(0) \rangle = \int d\alpha_{32} \frac{\hat{C}(\alpha_3, \kappa_2 h_1, \alpha_{32})\hat{C}(2Q - \alpha_{32}, \kappa_4 h_1, \alpha_1)}{\langle \hat{V}_{2Q-\alpha_{32}}\hat{V}_{\alpha_{32}} \rangle} \mathcal{F} \left[ \begin{array}{ccc} \kappa_2 h_1 \\ \kappa_4 h_1 \\ \alpha_1 \end{array} \right] \mathcal{F} \left[ \begin{array}{ccc} \alpha_3 \\ \alpha_{32} \\ \kappa_4 h_1 \end{array} \right] (x)^2
\]
Again, we normalize these u-channel conformal blocks so that their leading term is a power of \((-x\)), namely \(\mathcal{F}_{\alpha_1\alpha_2}(x) \sim (-x)^{\Delta(\alpha_1) - \Delta(\alpha_2) - \Delta(\kappa_2h_1)}\). Both sets of conformal blocks are analytic on \(\mathbb{C} \setminus [0, \infty)\). The two decompositions are related by an integral transformation

\[
\mathcal{F}^{(u)}_{\alpha_1\alpha_2}(x) = \int d\alpha_{32} B_{\alpha_1\alpha_2;\alpha_3\alpha_4} \mathcal{F}^{(u)}_{\alpha_3\alpha_4}(x) .
\]  

(4.3)

Our goal is to find the braiding kernel \(B_{\alpha_1\alpha_2;\alpha_3\alpha_4}\).

From section 3.2 we know this braiding kernel in the limit \(\kappa_2 h_1 \to -Kb h_1\), in other words when one of the semi-degenerate operators turns into a degenerate operator. Then it is a sum of residues (hence an integral) of a product of sines (3.42) which involve various multiples of \(b^2\) in their arguments. This product of sines can be recast in terms of the double Sine function \(S_b\) which obeys \(S_b(x + nb)/S_b(x) = \prod_{\mu=0}^{n-1} 2 \sin \pi (bx + \mu b^2)\) (see section 2.3 on special functions). The braiding kernel for generic \(\kappa_2\) should thus be an integral of some \(S_b\) functions. Writing all generic momenta as \(a = Q - i\alpha\), we propose

\[
B_{\alpha_1\alpha_2;\alpha_3\alpha_4} \left[ \frac{\kappa_4 h_1 \kappa_2 h_1}{\alpha_3 \alpha_1} \right] = i^{N-1} \prod_{s \neq t} \frac{\Gamma_b(b + b - 1 + \langle ia_1, h_s - h_t \rangle)}{\Gamma_b(\langle ia_3, h_s - h_t \rangle)} 
\]

\[
\times \prod_{s,t=1}^N \frac{\Gamma_b(\langle ib_3, h_s \rangle - \langle ia_3, h_t \rangle) \Gamma_b(b + b - 1 - \langle ia_1, h_s \rangle - \langle ia_3, h_t \rangle)}{\Gamma_b(\langle ia_1, h_s \rangle + \langle ia_3, h_t \rangle) \Gamma_b(b + b - 1 - \langle ia_3, h_s \rangle - \langle ia_3, h_t \rangle)} 
\]

\[
\times \int \prod_{i \neq j}^{N-1} \prod_{s=1}^{N-1} \prod_{j=1}^{N-1} S_b(i\tau_i - i\tau_j) \left[ S_b(-\langle ia_3, h_s \rangle + i\tau_j) S_b(\frac{a_2 + a_4}{N} - b - b - 1 + \langle ia_1, h_s \rangle + i\tau_j) \right] \left[ S_b(\frac{a_2 + a_4}{N} - \langle ia_3, h_s \rangle + i\tau_j) S_b(\frac{a_2 + a_4}{N} + \langle ia_1, h_s \rangle + i\tau_j) \right]
\]  

(4.4)

up to a constant factor that does not depend on any momentum. The integration contours go from \(-\infty\) to \(\infty\) with poles of the numerator \(S_b\) functions above the contours, and zeros of the denominator below them. For instance, if all components \(\langle ia_1, h_s \rangle\), \(\langle ia_3, h_s \rangle\), \(\langle ia_3, h_s \rangle\) are purely imaginary and all \(\text{Re} \frac{a_2}{N} = (b + b^{-1})/2\) then contours can be taken to be horizontal lines with \(-3b(b + b^{-1})/2 < \text{Im}(\tau) < 0\). For other values of momenta, the contour is deformed to keep the same set of poles on each side. Another remark is that \(\prod_{i \neq j}^{N-1} S_b(i\tau_i - i\tau_j)\) has no pole: it simplifies to a product of sines (4.13).

In a normalization of conformal blocks where the leading term is a power of \(x\), the braiding kernel includes phases, depending on the sign \(\epsilon\) of \(\text{Im}(x)\):

\[
B_{\alpha_1\alpha_2;\alpha_3\alpha_4} \left[ \frac{\kappa_4 h_1 \kappa_2 h_1}{\alpha_3 \alpha_1} \right] = \epsilon^{\pi\epsilon(\Delta(\alpha_1) - \Delta(\alpha_2) + \Delta(\alpha_2) - \Delta(\alpha_3))} B_{\alpha_1\alpha_2;\alpha_3\alpha_4} \left[ \frac{\kappa_4 h_1 \kappa_2 h_1}{\alpha_3 \alpha_1} \right]
\]  

(4.5)

A preliminary check of (4.4) is that it reproduces known results [44] for the Liouville theory \((N = 2)\). In their equation (48) replace their \(Q\) by \(b + b^{-1}\), shift the integration variable \(s \to s - a_2 + a_4 - (b + b^{-1})/2\), then map \(a_2 \to b - b^{-1} - a_2\) (for \(N = 2\) this is a Weyl symmetry). The factors with \(U_{3,4}\) become \(S_b(\pm(a_3 - (b + b^{-1})/2) + s)\). The factors with \(U_{1,2}\) become \(S_b(\pm(a_3 - (b + b^{-1})/2) + s)\). Thus, the integrand from [44, 45] coincides with that of (4.4) for \(N = 2\). It is straightforward to check that prefactors also coincide.
4.2 Reduction to fully degenerate

We now describe how to take the limit $\kappa_2 h_1 \to -K b h_1$ in (4.4), and retrieve the sum of residues from section 3.2.

The integrand in (4.4) has poles at

$$i\tau_j = \begin{cases} 
(ia_5, h_s) - mb - n/b & \text{if } j \neq 0 \\
(b + b^{-1} - \frac{a_5}{N} - \frac{a_4}{N} - (ia_1, h_s) - mb - n/b & \text{if } j = 0
\end{cases}$$

(4.6)

and

$$i\tau_j = \begin{cases} 
b + b^{-1} - \frac{a_5}{N} + (ia_{32}, h_s) + mb + n/b & \text{if } j \neq 0 \\
b + b^{-1} - \frac{a_4}{N} - (ia_{12}, h_s) + mb + n/b & \text{if } j = 0
\end{cases}$$

(4.7)

for integers $m, n \geq 0$. As mentioned before, the contour for $i\tau$ is chosen with poles (4.6) on the left and poles (4.7) on the right. This is possible as long as the two sets of poles are disjoint. Otherwise, the contour is pinched between the two sets and the integral diverges.

To understand the divergence, consider a simple model of a contour integral pinched by poles getting close together from the two sides of the contour. Let $f(z)$ be holomorphic in a neighborhood of $a$, and $a_L$ and $a_R$ be points in this neighborhood. Then

$$\int_{\text{between}} dz \frac{f(z)}{(z - a_L)(z - a_R)} = 2\pi i \frac{f(a_L)}{a_L - a_R} + \int_{\text{left}} dz \frac{f(z)}{(z - a_L)(z - a_R)}$$

(4.8)

where the initial contour goes between the two points, with $a_L$ on its left and $a_R$ on its right, and where the second contour is moved through $a_R$. As $a_L, a_R \to a$, the second term is regular, so the residue is $2\pi i f(a)$. This residue is obtained from the original integrand by taking the limit $a_L, a_R \to a$ then considering the second residue of the result $f(z)/(z-a)^2$. We denote this operation of taking the second residue as res$^2$.

In our case there are two rather different pinchings by poles (4.6) and (4.7). Whenever one of the (4.6) is equal to $b + b^{-1} - \frac{a_5}{N} + (ia_{32}, h_s) + mb + n/b$ the braiding kernel is singular. In fact, these singularities, together with those of numerator $\Gamma_b$ functions in (4.4), precisely reproduce singularities of the $u$-channel Toda CFT three-point functions:

$$\tilde{C}(\alpha_3, \kappa_2 h_1, 2Q - \alpha_{32}) = \prod_{t, u} \frac{1}{\Upsilon_t(\frac{T}{N} + (ia_3, h_t) - (ia_{32}, h_u))\Upsilon_u(\frac{T}{N} + (ia_1, h_t) + (ia_{32}, h_u))}.$$

(4.9)

It may be interesting to pursue further the analysis by considering multiple singularities, keeping in mind the constraints $\sum_i \langle ia_j, h_l \rangle = 0$ for each momentum. On the other hand, if one of the (4.6) is equal to $b + b^{-1} - \frac{a_5}{N} - (ia_{12}, h_s) + mb + n/b$, the contour is also pinched, but the prefactors in (4.4) (specifically the denominator $\Gamma_b$ functions) cancel the singularity so the braiding kernel can have a finite limit.

We are ready to consider our limit of interest: $\kappa_2 = -K b + N i \varepsilon$ for $\varepsilon \to 0$ (and $\varepsilon > 0$). The OPE of $\bar{V}_{-K b h_1}$ with a generic vertex operator constrains $\alpha_{12}$ and $\alpha_{32}$, so we further focus on $\alpha_{12} = \alpha_1 - bh[n]$ and $\alpha_{32} = \alpha_3 - bh[n]$ for some weights $h[n]$ and $h[n]$ in $\mathcal{R}(K h_1)$. 

To simplify some expressions we write \( \kappa_4 = \kappa + Kb \). We keep \( \alpha_1 \) and \( \alpha_3 \) generic. The poles (4.6) and (4.7) are now respectively at

\[
ir_j = \begin{cases} 
\langle ia_3, h_s \rangle - mb - n/b, \\
b + b^{-1} - \frac{\kappa}{N} - \langle ia_1, h_s \rangle - mb - n/b - \varepsilon,
\end{cases} \tag{4.10}
\]

\[
ir_j = \begin{cases} 
\langle ia_3, h_s \rangle + b\bar{n}_s + mb + n/b - \varepsilon, \\
b + b^{-1} - \frac{\kappa}{N} - \langle ia_1, h_s \rangle - bn_s + mb + n/b.
\end{cases} \tag{4.11}
\]

Because the momenta \( \alpha_1 \) and \( \alpha_3 \) are generic, the contour is pinched as \( \varepsilon \to 0 \) precisely when \( ir_j = b + b^{-1} - \frac{\kappa}{N} - \langle ia_1, h_s \rangle - bl \) for any \( 1 \leq j \leq N - 1, 1 \leq s \leq N \) and \( 0 \leq l \leq n_s \). The most singular contribution to the integral, of order \( 1/\varepsilon^{N-1} \), comes from values of \( ir \) where all \( ir_j \) take this form.

We only describe the contour integral part of the braiding matrix (4.4), as prefactors only lengthen computations. The coefficient of the term of order \( 1/\varepsilon^{N-1} \) in this integral is

\[
I = \prod_{j=1}^{N-1} \left[ \sum_{p_j=1}^{N} \sum_{k_j=0}^{n_{p_j}} \text{res} \right] \left\{ \prod_{i \neq j}^{N-1} \frac{1}{S_b(ir_i - ir_j)} \right\} \times \left[ \prod_{j=1}^{N-1} \prod_{s=1}^{N} \left[ \frac{S_b(-\langle ia_3, h_s \rangle + ir_j)}{S_b(\frac{\kappa}{N} - b - b^{-1} + \langle ia_1, h_s \rangle + ir_j)} \right] \right]\tag{4.12}
\]

Note that

\[
\prod_{i \neq j}^{N-1} \frac{1}{S_b(ir_i - ir_j)} = \prod_{i < j}^{N-1} \left(-4\sin \pi b(ir_i - ir_j) \sin \frac{\pi}{b}(ir_i - ir_j) \right). \tag{4.13}
\]

The shift relations for \( \Gamma_b \) and \( S_b \) yield

\[
I = \prod_{j=1}^{N-1} \left[ \sum_{p_j=1}^{N} \sum_{k_j=0}^{n_{p_j}} \text{res} \right] \left\{ \prod_{i < j}^{N-1} \frac{-4b^2 \cos \pi b\bar{n}_s}{\sin \frac{\pi}{b}(ir_i - ir_j)} \sin \frac{\pi}{b}(ir_i - ir_j) \right\} \times \left[ \prod_{j=1}^{N-1} \prod_{s=1}^{N} \left[ \frac{2\sin \frac{\pi}{b}(\frac{\kappa}{N} - b - b^{-1} + \langle ia_1, h_s \rangle + ir_j)}{2\sin \pi(-b^2 + \mu b^2 + b\langle ia_3, h_s \rangle + b\bar{n}_s)} \right] \right]. \tag{4.14}
\]

This expression differs from the desired sum of residues (3.42) in the following respects: a redefinition \( ir_j \to bi r_j + \frac{\kappa}{N} - b^2 - 1 \), a sum over choices of the \( p_j \), and additional factors of the form \( \sin \frac{\pi}{b} (\cdots) \). Because of antiperiodicity of sine these factors are independent of the \( k_j \) except for a sign. After extracting a sign, these factors are

\[
\prod_{j=1}^{N-1} \prod_{s=1}^{N} \left[ \frac{2\sin \pi(-b^2 + \mu b^2 + b\langle ia_3, h_s \rangle + b\bar{n}_s)}{2\sin \pi(-b^2 + \mu b^2 + b\langle ia_3, h_s \rangle + b\bar{n}_s)} \right] = \begin{cases} 
0 & \text{if two } p_i \text{ coincide, otherwise} \\
1/\prod_{j=1}^{N-1} \prod_{i=j+1}^{N} \sin \frac{\pi}{b}(\langle ia_1, h_{p_i} - h_{p_j} \rangle),
\end{cases} \tag{4.15}
\]
where \( p_N \) denotes the (single) element of \([1, N] \setminus \{p_i | i < N\}\) so that \( p \) is a permutation of \([1, N]\). Then these factors are independent of the permutation \( p \), except for a sign: the signature of \( p \). For each permutation \( p \) we get a sum of residues times the signature of \( p \), and this structure coincides with that of (3.42). Below that equation we had proven that it is independent of the permutation, hence summing over permutation simply introduces a trivial factor. We have thus reproduced qualitatively the structure of the braiding matrix of \( \hat{V}_{-K\bar{h}1} \) by taking the appropriate limit of the braiding kernel. The exact reduction of the braiding kernel to the braiding matrix is confirmed by a more detailed calculation.

### 4.3 Shift relation from pentagon identity

Braiding and fusion kernels (or matrices) obey Moore-Seiberg pentagon and hexagon relations. Here we consider a particular pentagon relation shown in figure 1. Going through the moves 1 \rightarrow 2 \rightarrow 3 we find

\[
\mathcal{F}[1] = \int \, d\alpha_{32} \, B_{\alpha_1 \alpha_2 \alpha_3} \, \left[ \frac{\kappa_4 h_1 \, \kappa_2 h_1}{\alpha_3 \, \alpha_1} \right] \mathcal{F}[2]
\]

\[
= \int \, d\alpha_{32} \sum_{s=1}^{N} \, B_{\alpha_1 \alpha_2 \alpha_3} \, \left[ \frac{\kappa_4 h_1 \, \kappa_2 h_1}{\alpha_3 \, \alpha_1} \right] \mathcal{F}_s \left[ \frac{(\kappa_2 + b) h_1 \, -bh_1}{2Q - \alpha_3} \right] \mathcal{F}[3].
\]  

(4.16)

On the other hand, going through the moves 1 \rightarrow 4 \rightarrow 5 \rightarrow 3 yields

\[
\mathcal{F}[1] = \sum_{p=1}^{N} \, F_p \left[ \frac{(\kappa_2 + b) h_1 \, -bh_1}{2Q - \alpha_1} \right] \mathcal{F}[4]
\]

\[
= \sum_{p=1}^{N} \int \, d\alpha'_{32} \, F_p \left[ \frac{(\kappa_2 + b) h_1 \, -bh_1}{2Q - \alpha_1} \right] \, B_{\alpha_1 \alpha_2 \alpha_3} \left[ \frac{\kappa_4 h_1 \, (\kappa_2 + b) h_1}{\alpha_3 \, \alpha_1 - bh_p} \right] \mathcal{F}[5]
\]

\[
= \sum_{p,s=1}^{N} \int \, d\alpha'_{32} \, F_p \left[ \frac{(\kappa_2 + b) h_1 \, -bh_1}{2Q - \alpha_1} \right] \, B_{\alpha_1 \alpha_2 \alpha_3} \left[ \frac{\kappa_4 h_1 \, (\kappa_2 + b) h_1}{\alpha_3 \, \alpha_1 - bh_p} \right] \, B_{ps} \left[ \frac{\kappa_4 h_1 \, -bh_1}{\alpha_3' \, \alpha_1} \right] \mathcal{F}[3].
\]  

(4.17)

The coefficients of each conformal block \( \mathcal{F}[3] \) (these are labelled by the choice of \( 1 \leq s \leq N \) and \( \alpha_{32} = \alpha'_{32} - bh_s \)) must be the same in (4.17) and (4.20).

To check that the proposal (4.4) obeys the pentagon identity, we will need the braiding matrix obtained from (3.24) using \( \alpha_1 = Q - ia_1 \) and \( \alpha'_{32} = Q - ia_{32} + bh_s \):

\[
B_{ps} \left[ \frac{\kappa_4 h_1 \, -bh_1}{\alpha_3' \, \alpha_1} \right] = \frac{\Gamma(1+b\langle ia_1, h_t-h_p \rangle)}{\Gamma(b\langle h_{n+1} - b\langle ia_1, h_t \rangle \rangle + b\langle ia_{32}, h_s \rangle - b^2) \prod_{u \neq s} \Gamma(1-b\langle h_{n+1} - b\langle ia_1, h_p \rangle \rangle - b^2)} \frac{\Gamma(b\langle h_{n+1} - b\langle ia_{32}, h_u \rangle \rangle - b^2)}{\prod_{u \neq s} \Gamma(1-b\langle h_{n+1} - b\langle ia_1, h_p \rangle \rangle - b^2)}.
\]  

(4.21)
denote $i$ simplify it in order to (4.17). All generic momenta are written as deduced from the braiding matrix (3.24), as done in equation (B.14) of the reference [56].

We will also need coefficients of the fusion of $(\kappa + b)h_1$ and $-bh_1$ into $\kappa_2 h_1$, which can be deduced from the braiding matrix (3.24), as done in equation (B.14) of the reference [56].

$$F_p \left[ \frac{(\kappa + b)h_1}{2Q - \alpha_{12}} \right] B_{\alpha_{12}\alpha_{32}} \left[ \frac{\kappa_4 h_1}{\alpha_3 - bh_p} \right] B_{ps} \left[ \frac{\kappa_4 h_1}{\alpha_1} \right] = \Gamma(b_{c_2}) \prod_{t \neq p} \Gamma(b(ia, h_p - h_t)) \prod_{t=1}^N \Gamma(b(ia, h_p) + b(ia^t, h_t)).$$ (4.22)

We now write down (4.20) explicitly for a fixed choice of $\alpha_{32}$ and of $1 \leq s \leq N$, and simplify it in order to find (4.17). All generic momenta are written as $\alpha = Q - ia$ and we denote $ia^u = (ia, h_u)$ for conciseness. Note that $\alpha'_{32} = Q - ia_{32} + bh_s$.

Let us start!

$$\sum_{p=1}^N F_p \left[ \frac{(\kappa + b)h_1}{2Q - \alpha_{12}} \right] B_{\alpha_{12}\alpha_{32}} \left[ \frac{\kappa_4 h_1}{\alpha_3 - bh_p} \right] B_{ps} \left[ \frac{\kappa_4 h_1}{\alpha_1} \right] = \prod_{t \neq p} \Gamma(b(ia, h_p - h_t)) \prod_{t=1}^N \Gamma(b(ia, h_p) + b(ia^t, h_t)).$$

$$\sum_{p=1}^N \left( \Gamma(b_{c_2}) \prod_{t \neq p} \Gamma(b(ia, h_p - h_t)) \prod_{t=1}^N \Gamma(b(ia, h_p) + b(ia^t, h_t)) \right) \times \prod_{t,u=1}^N \left[ \frac{\Gamma_b \left( \frac{\alpha^u}{N} + \alpha^u_{32} - ia^u_{32} + b \delta_{s,u} \Gamma_b \left( b + b^{-1} - i \alpha^u_{12} - ia^u_{32} - b \delta_{p,t} + b \delta_{s,u} \right) \right)}{\Gamma_b \left( \frac{\alpha_{32}}{N} + \alpha_{32} - b \delta_{s,t} + b \delta_{s,u} \Gamma_b \left( b + b^{-1} - \frac{\alpha_{32}}{N} - ia^u_{32} - b \delta_{p,t} + b \delta_{s,u} \right) \right)} \right) \times \int \frac{d^{N-1} \tau_j}{\prod_{i \neq j} \Gamma_b \left( i \tau_j - i \tau_j \right)} \prod_{j=1}^{N-1} \prod_{t=1}^N S_b(-ia^u_{32} + i \tau_j) S_b \left( \frac{\alpha^u}{N} - b - b^{-1} + i \alpha^u_{12} + i \tau_j + b \delta_{p,t} \right) \times \prod_{t \neq p} \Gamma(b(ia^u_{32} - b \delta_{p,t} + b \delta_{s,u} + b \delta_{s,u})).$$ (4.23)
We collect factors which do not depend on \( p, s \) using shift relations of \( \Gamma_b \) and \( S_b \). Factors of \( \sqrt{2\pi} \) and powers of \( b \) cancel, and we combine many Gamma as \( \Gamma(x)\Gamma(1-x) = \pi/\sin \pi x \).

\[
\begin{align*}
&= \prod_{t, u=1}^N \left[ \frac{\Gamma_b\left( \frac{\pi}{2N} + ia_1^t - ia_1^u \right) \Gamma_b(b + b^{-1} - \frac{\pi}{4} - ia_1^t - ia_1^u)}{\Gamma_b\left( \frac{\pi}{2N} + ia_1^t - ia_1^u \right) \Gamma_b\left( \frac{\pi}{2N} - ia_1^t - ia_1^u \right)} \right] \prod_{t \neq u}^N \left[ \frac{\Gamma_b(b + b^{-1} + ia_3^t - ia_3^u)}{\Gamma_b(ia_3^t - ia_3^u)} \right] \\
&\times \int \frac{d^{N-1}\tau_j}{\prod_{b \neq j} S_b(\tau_j - i\tau_j)} \left\{ \prod_{j=1}^{N-1} \prod_{t=1}^N \left[ \frac{S_b(-ia_3^j + i\tau_j)S_b\left( \frac{\pi}{4} + \frac{\pi}{4} - b - b^{-1} + ia_1^t + i\tau_j \right)}{S_b\left( \frac{\pi}{4} - ia_3^t + i\tau_j \right)S_b\left( \frac{\pi}{4} + ia_1^t + i\tau_j \right)} \right] \right. \\
&\left. \times \frac{\Gamma(b\kappa_2)\prod_{a \neq \pm 1} \Gamma(bia_3^j - bia_3^a) \prod_{j=1}^{N-1} \frac{1}{2} \sin \pi\left( \frac{b\kappa_4}{2N} + bia_1^t + bia_3^j - b^2 \right) \prod_{t=1}^N \frac{1}{2} \sin \pi\left( \frac{b\kappa_4}{2N} + bia_1^t + bia_3^t - b^2 \right)}{\prod_{j=1}^{N-1} \frac{1}{2} \sin \pi\left( \frac{b\kappa_4}{2N} + bia_1^j + bia_3^j - b^2 \right) \prod_{t=1}^N \frac{1}{2} \sin \pi\left( \frac{b\kappa_4}{2N} + bia_1^t + bia_3^t - b^2 \right)} \right\} (4.24)
\end{align*}
\]

The last line is a sum of residues at \( v = bia_1^p \) of \( \prod_{j=1}^{N-1} \frac{1}{2} \sin \pi\left( \frac{b\kappa_4}{2N} + bia_1^j + bia_3^j - b^2 \right) \prod_{t=1}^N \frac{1}{2} \sin \pi\left( \frac{b\kappa_4}{2N} + bia_1^t + bia_3^t - b^2 \right) \), which is equal to minus its residue at the last pole \( v = b^2 - \frac{b\kappa_4}{2N} - bia_3^2 \). That residue turns out to cancel most factors in the second to last line. Together, these last two lines of (4.24) are equal to

\[
\Gamma(b\kappa_2)\prod_{a \neq \pm 1} \Gamma(bia_3^j - bia_3^a) = \mathbf{F}_a\left[ \begin{array}{c} (\kappa_2 + b)h_1 \\ \alpha_3 \\ 2Q - \alpha_3^a \end{array} \right] .
\]

In particular, this does not depend on \( i\tau_j \) and can be pulled out of the integral. The first two lines of (4.24) then reproduce precisely the braiding matrix (4.4) of two semi-degenerate vertex operators. This concludes our check of the pentagon relation (4.17) = (4.20).

This pentagon relation expresses the braiding kernel \( \mathbf{B}_{\alpha_1 \alpha_2} \) as a sum of \( N \) braiding kernels with \( \kappa_2 \rightarrow \kappa_2 + b, \alpha_1 \rightarrow \alpha_1 - bh_p \) and \( \alpha_3 \rightarrow \alpha_3 = \alpha_3 + bh_s \). Thus, if the braiding kernel was known for some value \( \kappa_2 = \lambda \), it could be deduced for \( \kappa_2 = \lambda - Kb \) for integer \( K \geq 0 \). The pentagon identity (1 \( \rightarrow 2 \rightarrow 3 \rightarrow 5 ) = (1 \rightarrow 4 \rightarrow 5 ) \) is checked through very similar computations. It allows the opposite shifts: from the \( \kappa_2 = \lambda \) braiding kernel one gets the \( \kappa_2 = \lambda + Kb \) braiding kernel. By symmetry, identical shift relations exist with \( b \rightarrow \frac{1}{b} \), thus fixing braiding kernels for \( \kappa_2 = \lambda + Kb + L/b \) for all integers \( K, L \). For generic real \( b^2 \), continuity would then determine the braiding kernel uniquely. Of course, this logic requires knowing for some \( \kappa_2 \) that the braiding kernel is correct for all values of other momenta.

From the trivial braiding kernel at \( \kappa_2 = 0 \) the shift relations allow us to reach all degenerate momenta \( \kappa_2 = -Kb - Lb^{-1} \) for \( K, L \geq 0 \), thus proving in particular that the braiding matrix (3.42) (\( L = 0 \)) is correct. On the other hand, operators \( \hat{V}_{-Kb-Lb^{-1}} \) vanish if \( K = -1 \) or \( L = -1 \), which prevents us from using the pentagon relation to deduce prove our answer for \( K < -1 \) or \( L < -1 \).

To establish the proposed braiding kernel a strategy could be to derive shift relations on each momentum separately as was done in the Liouville case. We hope to return to this in the future. In the mean-time, the shift relations that we have already proven are at least very strong evidence that the proposed braiding kernel is correct.
5 Domain wall and its symmetries

We want to describe the S-duality domain wall of 4d $\mathcal{N} = 2$ SU($N$) SQCD as a 3d $\mathcal{N} = 2$ gauge theory coupled to the bulk on both sides. As explained in section 2, its $S^3_b$ (ellipsoid) partition function is equal, up to prefactors (2.8), to the $W_N$ braiding kernel (4.4) that we just computed. To warm up we explain in section 5.1 how continuous flavour symmetries of the 4d/3d coupled systems given in the introduction reproduce those expected of the S-duality wall. Then we move on in section 5.2 to more involved expressions: comparing the braiding kernel to localization results. In fact, these are the formulas from which we read off the announced 3d U($N_1$) and USp($2N_2$) gauge theories. Section 5.3 matches $\mathbb{Z}_2$ symmetries of the $W_N$ braiding, of the abstract S-duality wall, and of its concrete 3d gauge theory description.

Most interestingly, charge conjugation of 4d theories is not a manifest symmetry of the 3d theory. To show that our explicit expressions are invariant we lift the 3d partition function of the USp($2N_2$) theory to a 4d index then use Seiberg duality for USp groups. Alternatively, a physical understanding was obtained in [42] (after version 1 of this paper) where a variant of Aharony duality was found, under which our U($N-1$) theory is self-dual. Finally, we discuss peculiarities for $N = 2$ due to USp($2$) = SU(2).

5.1 Continuous flavour symmetries

Before turning to partition functions and how we obtained the following descriptions we explain how continuous flavour symmetries of the 4d/3d coupled systems reproduce those expected of the S-duality wall. The two quiver descriptions are (with notations below)

\[
\text{(S-duality wall)} = Z \left[ \begin{array}{c} \text{U}(N-1) \\ \text{SU}(N) \end{array} \right]_{\text{4d}} = \lim_{\mu \to \pm \infty} Z \left[ \begin{array}{c} \text{USp}(2N-2) \\ \text{SU}(N) \end{array} \right]_{\text{4d}} \tag{5.1}
\]

with superpotential

\[
W = \sum_{f=1}^{2N} \sum_{s=1}^{N} \left( \Phi_{fs} |_{3d} q_f + \Phi_{fs} |_{3d} q'_f \right) + \begin{cases} V_+ + V_- & \text{for the U}(N-1) \text{ theory,} \\ Y & \text{for the USp}(2N-2) \text{ theory.} \end{cases} \tag{5.2}
\]

The quivers denote 4d/3d coupled systems involving a 3d $\mathcal{N} = 2$ gauge theory with U($N-1$) or USp($2N-2$) gauge group, $2N$ fundamental chiral multiplets $q_f$, $N + N$ antifundamentals $\tilde{q}_s$, $\tilde{q}'_s$, and a monopole superpotential made of all minimal monopoles $V_+$ or $Y$ for the given gauge group. The SU($N$) flavour symmetries of $\tilde{q}$ and $\tilde{q}'$ in this theory are each gauged using the 3d restriction of the 4d $\mathcal{N} = 2$ SU($N$) vector multiplet on one side of the wall. The 3d superpotential (5.2) is built using the 3d $\mathcal{N} = 2$ chiral multiplets and using restrictions $\Phi_{3d}$ and $\Phi'_{3d}$ of the 4d $\mathcal{N} = 2$ hypermultiplets of both SQCD theories. It is compatible with the SU($N$)$^2$ gauging and breaks many other symmetries as explained next, identifying for example the SU($2N$) flavour symmetries of $q$ and of bulk hypermultiplets.
The U(N − 1) theory with 2N flavours has an SU(2N)1 × SU(2N)2 × U(1)B × U(1)T flavour symmetry and U(1)R symmetry. Gauging an SU(N)2 subgroup of one SU(2N)1 using the two 4d gauge symmetries reduces that factor of the flavour symmetry to U(1)1. Besides being consistent with this identification, the superpotential breaks many 3d and 4d symmetries to their diagonal subgroup, thus identifying pairs of symmetries.

- The 3d symmetry SU(2N)2 is identified to the SU(2N) flavour symmetries of the two 4d theories by the first two terms in W. This reproduces the fact that S-duality identifies the SU(2N) flavour symmetries of dual theories.

- The first two terms in W further identify the U(1)1 symmetry to the difference of baryonic U(1)avour symmetries of the two 4d theories, and the 3d baryonic symmetry U(1)B to their sum.

- The dressed monopole operators V+ and V− have the same non-zero charge under the U(1)B flavour symmetry of the 3d theory and opposite charges under the topological one, so both U(1)B and U(1)T are broken by the superpotential terms V+ + V−. In particular, only the difference of 4d baryonic symmetries survives (further combined with U(1)1 as seen above). This reproduces the fact that the baryonic symmetry is flipped by S-duality.

Furthermore, W has R-charge 2 under the U(1)R symmetry of 3d N = 2. This is a subgroup of the SU(2)R symmetry of 4d N = 2, so U(1)R-charges of the 4d fields Φ and Φ′ are integers. By continuity these charges on $S^4$ must be equal to those in flat space, which are 1 since hypermultiplet scalars are in a doublet of SU(2)R. As a result, the R-charges of q and \(\tilde{q}\) must sum to 1, as do those of q and \(\tilde{q}'\). Up to a diagonal gauge redundancy, the superpotential thus sets R-charges of all 3d chiral multiplets to their canonical UV value \(\frac{1}{2}\). Since none of the remaining unbroken U(1) symmetries leave all chiral multiplets invariant, we learn that the UV and IR R-symmetries coincide. A consistency check is that under this UV R-symmetry of the 3d theory the monopole operators V± also have the correct R-charge.\(^{17}\) Symmetries and charges are summarized in table 2.

17Alternatively, one can start by analyzing the U(Nc) theory with Nf flavours and monopole superpotential, as done in [42]. The superpotential sets the R-charge of monopoles to 2, which fixes most possible mixing of R-symmetry with other symmetries, thus setting R-charges of q, \(\tilde{q}\), \(\tilde{q}'\) to their UV value. In this approach, the consistency check is that the cubic superpotential coupling with $\Phi|_{3d}$ and $\Phi'|_{3d}$ has the correct R-charge 2.
| Gauge symmetries | Global symmetries |

Table 2. Charges of 3d and 4d fields under unbroken symmetries for the two descriptions of the S-duality domain wall in (5.1). First we list gauge groups of the 3d theory and 4d theories, then flavour and $R$-symmetry groups. Charges coincide except for the additional symmetry $U(1)_A$ in the second case, and the possibility to mix it into the $R$-symmetry for some parameter $\nu$ with $|\nu| \leq 1/4$.

summarized in table 2, symmetries are identical to the previous model, except for the extra symmetry $U(1)_A$. To eliminate $U(1)_A$ we turn on a mass parameter $\mu$ for it, namely add $\pm \mu$ to the masses of chiral multiplets as indicated by the markings $+\mu$ and $-\mu$ in (5.1). We then take $\mu \to +\infty$. We will find that the $S^3$ partition function reduces to contributions from the neighborhood of a point $\tau_\mu = (\mu, \ldots, \mu, -\mu, \ldots, -\mu)$ of the Coulomb branch where only half of the chiral multiplets acquire a large mass $2\mu$. The gauge group is reduced to $U(N-1)$, and every fundamental chiral multiplet of $USp(2N-2)$ splits into a fundamental and an antifundamental one, one of which acquires a mass. The $\mu \to \pm \infty$ limit is then the $U(N-1)$ 3d theory in (5.1). A separate concern caused by $U(1)_A$ is that the $R$-symmetry of 3d $N^\prime = 2$ can mix with $U(1)_A$ along the RG flow, and one should perform $F$-extremization [38] for each value of $\mu$ to determine the IR $R$-charges. Very limited numerical tests suggests that $R$-charges remain bounded, so that their $\mu$ dependence does not affect the limit.
5.2 Partition function

5.2.1 U(N − 1) description

The coefficients in (2.8) are products of $1/Y_b(x) = \Gamma_b(x)\Gamma_b(b + b^{-1} - x)$ which combine with prefactors of the braiding kernel (4.4). Toda CFT momenta are converted to gauge theory parameters $a$ and $a'$ and hypermultiplet masses $m_f$ ($f = 1, \ldots, 2N$) using the dictionary (2.10), $\alpha_{12} = Q + \sum_{j=1}^{N} ia_jh_j$ and $\alpha_{32} = Q - \sum_{j=1}^{N} ia'_jh_j$. Denote $m = \sum_{f=1}^{2N} m_f/(2N)$, write $m_f = m + \tilde{m}_f$, shift all $\tau_j$ and use $1/S_b(x) = S_b(b + b^{-1} - x)$ to find what partition function to expect given our Toda CFT results:

$$\langle S\text{-duality wall on } S^3_b \subset S^3_0 \rangle = Z_{\text{1-loop, hyper}}^{\text{half-ellipsoid}}(m, a)Z_{\text{1-loop, hyper}}^{\text{half-ellipsoid}}(m, a') \prod_{i \neq j}^{N} \frac{\Gamma_b(i\tau_i - i\tau_j)}{\Gamma_b(i\tau_i + i\tau_j)}
\times \prod_{s=1}^{N} S_b\left(\frac{b + b^{-1}}{4} - im + ia_s + i\tau_s\right) \prod_{s=1}^{N} S_b\left(\frac{b + b^{-1}}{4} + im + i\tau_s\right) \prod_{i \neq j}^{N} \frac{\Gamma_b(i\tau_i - i\tau_j)}{\Gamma_b(i\tau_i + i\tau_j)}$$

The first line in (5.3) gives perfect candidates for the one-loop determinant of a hypermultiplet on a half-ellipsoid and that of a vector muliplet,

$$Z_{\text{1-loop, hyper}}^{\text{half-ellipsoid}}(m) = \prod_{a \in \text{roots}} \frac{1}{\Gamma_b(i\langle e | a \rangle)}
Z_{\text{1-loop, vector}}^{\text{half-ellipsoid}}(a) = \prod_{a \in \text{roots}} \frac{1}{\Gamma_b(i\langle e | a \rangle)}$$

where $\langle e | a \rangle$ is the usual scalar product of roots with elements of the Cartan algebra. These candidates appear to be consistent with results on the full ellipsoid: indeed,

$$Z_{\text{1-loop, hyper}}^{S^3_b}(m) = Z_{\text{1-loop, hyper}}^{\text{half-ellipsoid}}(m)Z_{\text{1-loop, hyper}}^{\text{half-ellipsoid}}(-m)$$

$$Z_{\text{1-loop, vector}}^{S^3_b}(a) = Z_{\text{1-loop, vector}}^{\text{half-ellipsoid}}(a)Z_{\text{1-loop, vector}}^{\text{half-ellipsoid}}(-a) / Z_{\text{1-loop, vector}}^{S^3_b}(a).$$

More precisely, the vector multiplet one-loop determinant is given here for the case of Neumann boundary conditions (namely gauge transformations are not frozen at the boundary). The need to divide by the one-loop determinant of a vector multiplet on $S^3_b$ is not surprising since we would otherwise be overcounting degrees of freedom.

We are left with the task of finding a 3d $\mathcal{N} = 2$ gauge theory whose $S^3_b$ partition function is the integral in (5.3). Such partition functions are known through supersymmetric localization [38–40]: the path integral is localized to field configurations where a real vector multiplet scalar takes an arbitrary constant value, which can be reduced to the
Cartan algebra of the gauge group $G$ by a gauge transformation. The partition function takes the form

$$Z_{S^6_b}(f) = \int_{-\infty}^{\infty} \prod_{j=1}^{\text{rank} G} \left[ d\tau_j e^{\pi i k \tau_j^2 e^{-2\pi \lambda \tau_j}} \right] \prod_{I} \prod_{w_I \in \mathcal{R}_I} S_6(\frac{1}{2}(b + b^{-1})r_I + i\langle w_I | \tau \rangle + im_I) \prod_{e \in \{ \text{roots} \} } S_6(i\langle e | \tau \rangle) \right),$$

(5.7)

where the exponentials are classical values of the action, with $k$ the Chern-Simons level (one per simple factor of $G$) and $\lambda$ the Fayet-Iliopoulos parameter (one per abelian factor of $G$), the product over roots $e$ of $G$ is the one-loop contribution of the vector multiplet, and finally each chiral multiplet transforming in a representation $\mathcal{R}_I$ of $G$ contributes a product over weights $w_I$ including multiplicity (we write $w_I \in \mathcal{R}_I$ for lack of a better notation), which involves the $R$-charge $r_I$ and mass $m_I$ of the chiral. The integration contour of each $\tau_j$ agrees with $\mathbb{R}$ away from a compact set and is chosen so that for each $S_6$ all the poles are above the contour or all below. Note that the vector multiplet contribution has no pole since $(S_6(1)|y\rangle S_6(-y)^{-1})^{-1} = -4\sin(\pi by)\sin(\pi b^{-1}y)$.

We now find what 3d $\mathcal{N} = 2$ theory reproduces (5.3) as follows. From the product of $S_6(i\tau_I - i\tau_J)$ which does not depend on masses we deduce that the gauge group is $U(N - 1)$. All remaining $S_6$ functions are one-loop determinants of chiral multiplets with canonical $R$-charge $\frac{1}{2}$ (since the arguments take the form $\frac{1}{4}(b + b^{-1}) + \cdots$). The multiplets are $2N$ fundamentals $q_f$ of $U(N - 1)$ with masses $-\hat{m}_f$ for $f = 1, \ldots, 2N$, and $2N$ antifundamentals $\tilde{q}_s$ with masses $a_s - m$ and $a'_s + m$ for $s = 1, \ldots, N$. These masses and $R$-charges are consistent with coupling the 3d and 4d matter multiplets along the defect using the cubic superpotential

$$W_{\text{cubic}} = \sum_{f=1}^{2N} \sum_{s=1}^{N} \left( \Phi_{|3d}| \tilde{q}_s q_f + \Phi'_{|3d}|3d \tilde{q}_s q_f \right).$$

(5.8)

Here $\Phi_{|3d}$ and $\Phi'_{|3d}$ are restrictions of 4d hypermultiplets at the interface; more precisely they are the 3d $\mathcal{N} = 2$ chiral multiplet whose bottom component is the 3d restriction of one complex scalar in the hypermultiplets. The $R$-charge of these fields originating from 4d must be an integer since the 3d $U(1)_R$ symmetry is embedded in the non-Abelian $SU(2)_R$. It must be precisely 1 because in flat space the scalars in 4d hypermultiplets transform in a doublet of $SU(2)_R$. Therefore every term in the superpotential has $R$-charge 2. It is immediate to check that other charges sum to zero for each term: $(\hat{m}_f + m - a_s) + (a_s - m) + (-\hat{m}_f) = 0$ and $(\hat{m}_f - m - a'_s) + (a'_s + m) + (-\hat{m}_f) = 0$.

As discussed in section 5.1 the superpotential identifies $SU(2N)$ symmetries of the 3d and 4d theories, and 3d $SU(N)$ symmetries to 4d gauge symmetries. It also breaks some $U(1)$ symmetries, but leaves four:

- $U(1)_R$, whose effect on the arguments of $S_6$ functions is to include a term $\frac{1}{4}(b + b^{-1})$,
- $U(1)_1$, whose mass parameter $m$ we see in masses $a_s - m$ and $a'_s + m$ of antifundamental chiral multiplets,
- $U(1)_R$, whose mass parameter would appear with the same sign in all $S_6$ functions,
- $U(1)_T$, whose mass parameter (the FI parameter) would appear as an exponential contribution $e^{-2\pi \lambda \sum_{j} \gamma_j}$. 

- 30 -
We thus need to add to the superpotential some terms that break $U(1)_B$ and $U(1)_T$. It turns out that the monopole operators $V_\pm$ do the trick, giving the superpotential (1.3).

As explained at the end of section 2.2, if instanton partition functions (conformal blocks) are normalized to have a leading term $x^{-\epsilon}$ rather than $(-x)^{-\epsilon}$, then the S-duality kernel is changed by phases (2.13) $\exp(\epsilon \pi \left[ \frac{1}{2} \sum_j a_j^2 + \frac{1}{2} \sum_j a_j'^2 \right])$ depending on the half-plane ($\epsilon = \pm 1$ is the sign of $\text{Im} x$). These phases are reproduced by a Chern-Simons term of level $\frac{1}{2}$ for 3d restrictions of the 4d gauge $SU(N)$ fields.

### 5.2.2 $USp(2N-2)$ description

We now consider the $USp(2N-2)$ theory in (5.1) and explain its partition function has the $U(N-1)$ one as a limit, up to a divergent factor $e^{N(N-1)\pi(b+b^{-1})\mu}$ omitted here. We wish to take $\mu \to \infty$ in the $S^3_\mu$ partition function

$$Z_{S^3_\mu} = \int d^{N-1}\tau \prod_{j=1}^{N-1} \left\{ \frac{\prod_{j=1}^{N-1} \prod_{j'=1}^{2N} S_b \left( \frac{b+b^{-1}}{4} - im_j - i\mu \pm i\tau_j \right)}{\prod_{j=1}^{N-1} S_b \left( \pm (i\tau_j + i\tau_j) \right) \prod_{j=1}^{N-1} S_b \left( \pm (i\tau_j - i\tau_j) \right)} \right\}.$$

(5.9)

From the asymptotics of $\Gamma_b$ [57, Proposition 8.11] we work out that for $|\chi| \to \pm \infty$ away from the imaginary axis,

$$S_b(A + i\chi)S_b(B - i\chi) \sim e^{-\pi(b+b^{-1}-A-B)\chi \text{sign}(\text{Re} \chi)} e^{\text{sign}(\text{Re} \chi) b^2 (\frac{1}{2}(b+b^{-1})-B)^2 - (\frac{1}{2}(b+b^{-1})-A)^2)}.$$

(5.10)

We will always take $\chi$ real so $\chi \text{sign}(\text{Re} \chi) = |\chi|$.

Let us apply (5.10) to pairs of $S_b$ functions in (5.9) which have opposite dependence on $\mu$ and $\tau_j$, taking $A$ and $B$ to be everything apart from $\mu$ and $\tau_j$. We ignore for now factors that are uniformly bounded functions of $\mu$ and $\tau_j$ (and have uniformly bounded inverse), and will denote them by (finite). This allows us to keep only the first exponential in (5.10). In fact, $S_b(A + i\chi)S_b(B - i\chi) = e^{-\pi(b+b^{-1}-A-B)|\chi|}(\text{finite})$. The integrand becomes

$$(\text{finite}) \exp \left( \pi(b+b^{-1}) \left( -N \sum_{j=1}^{N-1} |\mu - \tau_j| + |\mu + \tau_j| \right) + \sum_{i<j} N \sum_{i<j} |\tau_i - \tau_j| \right) \right).$$

(5.11)

Now $|\mu - \tau_j| + |\mu + \tau_j| = \max(2|\mu|, 2|\tau_j|)$ and $|\tau_i - \tau_j| + |\tau_i + \tau_j| = \max(2|\tau_i|, 2|\tau_j|)$. Sorting the parameters as $|\tau_1| < \ldots < |\tau_l| < |\mu| < |\tau_{l+1}| < \cdots < |\tau_{N-1}|$, the exponential is

$$\exp \left( \pi(b+b^{-1}) \left( -N(N-1)\mu \sum_{j=1}^{N-l} (|\mu| - |\tau_j|) - 2 \sum_{j=l+1}^{N-1} (N-j)(|\tau_j| - |\mu|) \right) \right).$$

(5.12)

The second and third terms are negative. Hence the dominant contribution to the integral (5.9) as $\mu \to \infty$ is when $|\tau_j| - |\mu|$ are finite, and away from these regions the integrand decays exponentially.
We can now go back and keep finite factors when expanding the integrand in the region $|\tau_j| \sim |\mu|$. Given symmetries under $\tau_j \to -\tau_j$, we focus on the case $\tau_j = \mu + \tilde{\tau}_j$ with $\tilde{\tau}_j$ finite. Half of the $S_b$ factors remain finite and form the partition function of the $U(N)_{\mu}$ theory, while the other half can be paired and turned into exponentials through (5.10). One gets

$$\lim_{\mu \to \pm \infty} \left[ E(\mu, b, m, \hat{m}, a, a') Z_{S_b}^3(U(2N-2) \text{ theory}) \right] = \int d^{N-1} \hat{\tau} \left\{ \prod_{j=1}^{N-1} \prod_{f=1}^{2N} S_b \left( \frac{b+b^{-1}}{4} - i\hat{m}_f + i\hat{\tau}_j \right) \prod_{i < j} S_b \left( \pm (i\tilde{\tau}_i - i\tilde{\tau}_j) \right) \prod_{j=1}^{N-1} \prod_{s=1}^{N} \left[ S_b \left( \frac{b+b^{-1}}{4} - im + ia_s - i\tilde{\tau}_j \right) S_b \left( \frac{b+b^{-1}}{4} + im + ia'_s - i\tilde{\tau}_j \right) \right] \right\}$$

(5.13)

where $E = \left[ \frac{1}{2} e^{N \pi (b+b^{-1}) |\mu|} e^{\text{sign}(\mu) \frac{\pi}{4} \left( \sum_{j=1}^{2N} \hat{m}_j^2 - \sum_{f=1}^{N} a_f^2 + \sum_{s=1}^{N} a'_s^2 - 2Nm^2 \right)} \right]^{N-1}$. As announced, the partition function of the $U(N-1)$ theory is a limit of the partition function of the $USp(2N-2)$ theory. See [42] for the analogous statement for the theories themselves, although one may want to keep track of the factor $E$, which consists of Chern-Simons terms for all flavour symmetry groups of the 3d theories.

### 5.3 Discrete symmetries and dualities

We now have all the necessary tools to study symmetries, from the point of view of the duality wall, of its 3d gauge theory description, and of the Toda CFT. Symmetries of Toda CFT correlators (hence of their braiding kernel) may be the least familiar to the reader, so we will describe them and give their gauge theory interpretation.

Any vertex operator $\hat{V}_\alpha$ is invariant under Weyl transformations, namely permutations of the components $(\alpha - Q, h_s)$. Applying this symmetry to $\hat{V}_\alpha$ permutes the first $N$ masses, and applying it to $\hat{V}_\alpha$ permutes the last $N$. These are manifest symmetries of the S-duality wall and of its 3d gauge theory description. In fact, permuting all of the $2N$ masses is also a symmetry, but the Toda CFT description does not make all permutations manifest.

Conformal blocks are invariant under conjugating all momenta, which maps (up to a Weyl transformation) $\alpha \to 2Q - \alpha$ and $\kappa h_1 \to (N(b+b^{-1}) - \kappa)h_1$ hence flips the sign of all $m_f, a_s$ and $\alpha'_s$. This is the effect of charge conjugation in the 4d theories on both sides of the wall, which is an expected symmetry of the S-duality wall. However, the effect is harder to describe in the 3d gauge theory description, because this theory is chiral, hence not invariant a priori under charge conjugation. Correspondingly, the explicit form of the braiding kernel does not appear invariant under charge conjugation. Most of this section will be spent proving the invariance, which will turn out to be a limit of $USp$-type Seiberg duality of $4d \, \mathcal{N} = 1$ indices. Before proceeding let us describe two more symmetries.

Conformal blocks are also invariant under some permutations of the operators. In particular, the braiding kernel is thus invariant under a permutation obtained by rotating...
the diagrams by 180° in the plane:

\[
\mathbf{B}_{\alpha_{12},\alpha_{32}} \left[ \frac{\kappa_4 h_1}{\alpha_3} \frac{\kappa_2 h_1}{\alpha_1} \right] = \mathbf{B}_{2Q-\alpha_{12},2Q-\alpha_{32}} \left[ \frac{\kappa_2 h_1}{\alpha_1} \frac{\kappa_4 h_1}{\alpha_3} \right] \quad \text{due to} \quad \frac{\alpha_3}{\alpha_1} \xrightarrow{\text{rotation}} \frac{\alpha_1}{\alpha_3}, \frac{\kappa_4 h_1}{\alpha_1} \xrightarrow{\text{rotation}} \frac{\kappa_2 h_1}{\alpha_3}, (5.14)
\]

The map \( \alpha_{12} \to 2Q - \alpha_{12} \) is due to the arrow being reversed by the rotation. Composing with conjugation of all momenta yields the transformation \( \alpha_1 \leftrightarrow 2Q - \alpha_3 \) and \( \kappa_2 \leftrightarrow N(b + b^{-1}) - \kappa_4 \), which given the dictionary (2.10) simply exchanges the first \( N \) and the last \( N \) masses.

Lastly, the S-duality wall and its 3d gauge theory description are invariant under exchanges of the two hemispheres. This symmetry is manifest in explicit expressions, but on the Toda side it is not immediately clear why it should hold. The symmetry maps \( a_s \leftrightarrow a_s' \) and \( m \to -m \). Momenta are mapped as \( \kappa_2 \leftrightarrow \kappa_4 \) and \( \alpha_{12} \leftrightarrow \alpha_{32} \), and the braiding kernel becomes the kernel for the inverse braiding, which expresses u-channel blocks in terms of s-channel ones. In addition to being inverses of each other, these braiding kernels are actually also equal up to some structure constants. To prove this, write the s-channel and u-channel decompositions of the four-point function, then use braiding kernels to get an expression with a holomorphic s-channel block and an antiholomorphic u-channel block, and match coefficients of \( \mathcal{F}_{\alpha_{12}}^{(s)}(x) \mathcal{F}_{\alpha_{32}}^{(u)}(\bar{x}) \):

\[
\langle \hat{\mathcal{V}} \hat{V} \hat{V} \hat{V} \rangle = \int \! d\alpha_{12} \, C^{(s)}(s) \mathcal{F}_{\alpha_{12}}^{(s)}(x) \mathcal{F}_{\alpha_{12}}^{(s)}(\bar{x}) = \int \! d\alpha_{12} \, d\alpha_{32} \, C^{(s)}(s) \mathcal{F}_{\alpha_{12}}^{(s)}(x) B_{\alpha_{12}\alpha_{32}} \mathcal{F}_{\alpha_{32}}^{(u)}(\bar{x}) \quad (5.15)
\]

\[
\langle \hat{V} \hat{V} \hat{V} \hat{V} \rangle = \int \! d\alpha_{32} \, C^{(u)}(u) \mathcal{F}_{\alpha_{32}}^{(u)}(x) \mathcal{F}_{\alpha_{32}}^{(u)}(\bar{x}) = \int \! d\alpha_{12} \, d\alpha_{32} \, C^{(u)}(u) B_{\alpha_{32}\alpha_{12}}^{2Q+4} \mathcal{F}_{\alpha_{12}}^{(s)}(x) \mathcal{F}_{\alpha_{32}}^{(u)}(\bar{x}). \quad (5.16)
\]

These two decompositions into the basis of functions \( \mathcal{F}_{\alpha_{12}}^{(s)}(x) \mathcal{F}_{\alpha_{32}}^{(u)}(\bar{x}) \) must coincide hence \( C^{(s)}(s) B_{\alpha_{12}\alpha_{32}} = C^{(u)}(u) B_{\alpha_{32}\alpha_{12}}^{2Q+4} \). The structure constants \( C^{(s)}(s) \) and \( C^{(u)}(u) \) turn out to cancel with the prefactors relating the braiding kernel to the S-duality wall partition function so that we get an equality of wall partition functions.

Now that we have described all manifest symmetries of the explicit braiding kernel (4.4), we must tackle invariance under charge conjugation.

We will use identities of hyperbolic hypergeometric integrals [58]. The hyperbolic Gamma function \( \Gamma^{(2)}_h \) of that paper reduces to our \( S_b(x) \) upon taking \( \omega_1 / \omega_2 = b^2 \). For definiteness, we take \( \omega_1 = i b \) and \( \omega_2 = i / b \) and note \( S_b(x) = \Gamma^{(2)}_h(2i x; i b, i / b) \). The \( B_{C_n} \) hyperbolic hypergeometric integral is defined by \( (\text{to avoid factors of } i \text{ we let } \mu_r = i \nu_r) \):

\[
I_{B_{C_n}h}^{(m)}(\nu_0, \ldots, \nu_{2m+2n+3}) = \frac{1}{2^{m} n!} \int_{\mathbb{R}^n} d^n x \prod_{\mu_{r}} \frac{\prod_{r=0}^{2m+2n+3} S_b(\nu_r + i x_{i}) \prod_{i=1}^{n} S_b(\pm (i x_{i} + i x_{j}) \prod_{i<j}^{n} S_b(\pm (i x_{i} - i x_{j}))}{(5.17)}
\]

for \( \sum_{r=0}^{2m+2n+3} \nu_r = (m + 1)(b + b^{-1}) \). Corollary 4.2 of [58] states the invariance under \( m \leftrightarrow n \) and \( \nu \to \frac{1}{2} (b + b^{-1}) - \nu \):

\[
I_{B_{C_n}h}^{(m)}(\nu_0, \ldots, \nu_{2m+2n+3}) = \prod_{r<s}^{2m+2n+3} S_b(\nu_r + \nu_s) \quad I_{B_{C_n}h}^{(n)}(b+b^{-1}/2 - \nu_0, b+b^{-1}/2 - \nu_1, \ldots), \quad (5.18)
\]
The $S_b^3$ partition function (5.9) of the USp($2N - 2$) SQCD with $4N$ chiral multiplets which we studied earlier is such a hyperbolic hypergeometric integral, with $m = n = N - 1$ and $4N$ parameters $\nu_r$ summing to $N(b + b^{-1})$:

$$Z_{S_b^3} = I_{BC_{N-1};B}^{(N-1)} \left( \frac{b+b^{-1}}{4} - i \hat{m}_f - i \mu \,(f = 1, \ldots, 2N), \right.)
\left. \frac{b+b^{-1}}{4} - i m + i a_s + i \mu, \frac{b+b^{-1}}{4} + i m + i a'_s + i \mu \,(s = 1, \ldots, N) \right) .$$

(5.19)

The identity (5.18) states that $Z_{S_b^3}$ is invariant up to a factor $\prod_{r<s} S_b(\nu_r + \nu_s)$ under changing the signs of all $\mu, \hat{m}_f, m, a_s, a'_s$.

We now take the limit $\mu \to \pm \infty$ in (5.18), after multiplying by $E(\mu)$ and $E(-\mu)$ respectively as explained in (5.13). On each side, we obtain partition functions of $U(N-1)$ theories, and the product of $S_b(\nu_r + \nu_s)$ reads

$$\prod_{r<s}^{4N-1} \prod_{f=1}^{2N} \prod_{s=1}^{N} \left[ S_b \left( \frac{b+b^{-1}}{2} - i \hat{m}_f - i m + i a_s \right) S_b \left( \frac{b+b^{-1}}{2} - i \hat{m}_f + i m + i a'_s \right) \right]$$

$$\times e^{-\mu \left( \sum_{f=1}^{2N} \hat{m}_f^2 - \sum_{s=1}^{N} a_s^2 - \sum_{s=1}^{N} a_s^2 - 2Nm^2 \right) (N-1) \text{sign} \mu} .$$

(5.20)

The phases are exactly $E(-\mu)/E(\mu)$ with $E$ defined below (5.13). The remaining $S_b$ functions are one-loop determinants of mesons formed as the product of a fundamental and an antifundamental chiral multiplet under $U(N-1)$. The full $S_b^3$ partition function (5.3) of the 4d/3d coupled system also includes one-loop determinants of hypermultiplets on half-ellipsoids, which are $\Gamma_b$ functions with the same arguments as the $S_b$ functions in (5.20) up to signs. Since

$$S_b \left( \frac{b+b^{-1}}{2} + x \right) = \frac{\Gamma_b \left( \frac{b+b^{-1}}{2} + x \right)}{\Gamma_b \left( \frac{b+b^{-1}}{2} - x \right)} ,$$

(5.21)

the $S_b$ functions coming from mesons in the 3d duality convert between $\Gamma_b \left( \frac{b+b^{-1}}{2} \pm x \right)$. This is fully consistent with 4d charge conjugation. Identical calculations show that the braiding kernel is invariant under Toda CFT charge conjugation.

The identity (5.18) was proven in [58] as a hyperbolic limit of an elliptic hypergeometric integral identity. In physics terms, the elliptic identity states that two Seiberg-dual 4d $\mathcal{N} = 1$ theories with USp($2N - 2$) gauge group and $4N$ fundamental chiral multiplets have the same $S_b^3 \times S^1$ partition function (supersymmetric index). Note that while the dual of 4d $\mathcal{N} = 1$ USp($2N_c$) SQCD with $2N_f$ fundamental chiral multiplets has $\widetilde{N}_c = N_f - N_c - 2$ colors, the analogous 3d $\mathcal{N} = 2$ Aharony duality has $\widetilde{N}_c = N_f - N_c - 1$ colors instead [43]. For our case $N_c = N - 1$ and $N_f = 2N$ the 4d theory is self-dual but the 3d theory is not. On the other hand, Aharony duality can be retrieved as a limit of (5.18) when $\nu_{2m+2n+2}, -\nu_{2m+2n+2} \to i \infty$. This is physically interpreted as dimensional reduction of 4d USp dualities down to 3d following [59, 60].

Let us finish this section with a mention of $N = 2$. Besides the USp-type Seiberg duality there is also an SU-type Seiberg duality in 4d in that case, thanks to the accidental isomorphism USp($2$) = SU($2$). The map of parameters for the SU($2$) Seiberg duality

---
depends on a split of the 8 chiral multiplets into 4 “fundamental” and 4 “antifundamental” ones. After descending to 3d \( \mathcal{N} = 2 \) partition functions,

\[
I_{BC;1;h}^{(1)}(\nu_0, \ldots, \nu_7) = \prod_{r=0}^{7} \prod_{s=4}^{3} \left( S_{\delta}(\nu_r + \nu_s) \right) I^{(1)}_{BC;1;h} \left( \frac{\nu_0 + \nu_1 + \nu_3 + \nu_2 + \nu_5 - \nu_1}{2}, \frac{\nu_0 + \nu_1 + \nu_3 + \nu_2 + \nu_5 + \nu_6 - \nu_7}{2}, \frac{\nu_0 + \nu_1 + \nu_3 + \nu_2 + \nu_5 + \nu_6 + \nu_7}{2} \right).
\]

As for general \( N \), we are interested in a limit where the \( \nu \) go to \( \pm i\infty \) (half with each sign). We can in particular choose \( +\nu_0, -\nu_1, -\nu_2, -\nu_3, +\nu_4, +\nu_5, +\nu_6, -\nu_7 \sim +i\mu \). Then most parameters in the dual (5.22) remain finite: only the first and the last depend on \( \mu \).

The limit \( \mu \to \infty \) then takes the \( S_6^3 \) partition function of SU(2) SQCD with 8 doublets to that of SU(2) SQCD with 6 doublets. This reproduces the 3d \( \mathcal{N} = 2 \) description found in [37] for the S-duality domain wall of 4d \( \mathcal{N} = 2 \) SU(2) SQCD with 4 flavours.

For \( N = 2 \), our description of the domain wall as a \( U(N - 1) = U(1) \) theory, namely 3d \( \mathcal{N} = 2 \) SQED with \( N_f = 4 \) flavours and a monopole superpotential was also found to be dual to SU(2) with 6 doublets in [41] by realizing both from dimensional reduction of a 4d theory with \( E_7 \) symmetry. It would be interesting to see if a similar construction could be performed for \( N > 2 \).

6 Conclusions

In this work we have determined the integral kernel (4.4) which braids two semi-degenerate vertex operators of the Toda CFT. Through the AGT relation, we have deduced the ellipsoid expectation value of an S-duality domain wall in 4d \( \mathcal{N} = 2 \) SU(\( N \)) SQCD with \( 2N \) flavours. We have then described the wall by coupling 3d \( \mathcal{N} = 2 \) U(\( N - 1 \)) SQCD with \( 2N + 2N \) chiral multiplets and a monopole superpotential on the wall to the 4d theories on both sides of the wall.

The shift relations found in section 4.3 do not appear sufficient to prove that the braiding kernel is correct. An obvious question would be to fill in this gap by checking additional Moore-Seiberg relations. It should be possible to extract Racah-Wigner coefficients for the modular double of \( U_q(sl_N) \), as was done for \( N = 2 \) in [44, 45], and to get 6j symbols of \( U_q(sl_N) \) by taking a limit of degenerate momenta, thus generalizing [61] from four symmetric to two symmetric representations of \( U_q(sl_N) \).

It would be valuable to evaluate one-loop determinants of hypermultiplets and vector multiplets on the half-ellipsoid with appropriate boundary conditions, and clarify whether the result indeed consists of half of the \( \Gamma_b \) factors in the full-ellipsoid results.

S-duality is expected to map Wilson loops to ’t Hooft loops. Expectation values of Wilson loop and ’t Hooft loop observables on the ellipsoid are known exactly [47, 62] and we now know the explicit S-duality kernel. Conjugating the Wilson loop by this kernel should thus yield the ’t Hooft loop, namely if one considers the 4d theory on \( S_4^4 \) with two S-duality walls near the equator and a Wilson loop in between, then the collision limit should yield a ’t Hooft loop. In fact, a preliminary question is to understand how the collision of two domain walls which perform S-duality and its inverse yields a trivial
operator. This annihilation should involve appropriate 3d dualities, as happens in one dimension higher in [30].

The S-duality wall generalizes straightforwardly to the case where part (or all) of the SU(2N) flavour symmetry shared by the two 4d theories is gauged by 4d vector multiplets. Class S theories, constructed by twisted dimensional reduction of the 6d (2, 0) SU(N) superconformal theory on a punctured Riemann surface Σ, provide interesting examples, for instance linear quivers of SU(N) gauge groups. The 3d description of an S-duality wall in such a quiver is again 3d \( \mathcal{N} = 2 \) U(N − 1) SQCD coupled with 4d fields through cubic superpotentials:

\[
N \xrightarrow{U(N-1)} N \xrightarrow{U(N-1)} N
\]

(6.1)

Quiver gauge theories open up the possibility of colliding S-duality domain walls, where S-duality acts on different gauge groups SU(N). When the groups are separated, the 3d description is obvious (on the Toda side the braiding operations commute):

\[
N \xrightarrow{U(N-1)} N \xrightarrow{U(N-1)} N
\]

(6.2)

When the two groups share a bifundamental hypermultiplet, the duality walls do not commute and we propose the following descriptions for the two possible orderings:

\[
N \xrightarrow{U(N-1)} N \xrightarrow{U(N-1)} N \quad \text{vs} \quad N \xrightarrow{U(N-1)} N \xrightarrow{U(N-1)} N
\]

(6.3)

with a cubic superpotential term coupling 3d and 4d fields for each triangle and a quartic superpotential for 3d chiral multiplets in the central parallelogram, as well as suitable monopole superpotentials. Such combinations of S-duality walls have been investigated (after version 1 of the present paper) in [63].

From the Toda CFT point of view, each of these products of duality walls corresponds to a product of two \( W_N \) braiding kernels. It may be interesting to translate Moore-Seiberg relations of braiding kernels into the gauge theory language and understand how 3d \( \mathcal{N} = 2 \) dualities reproduce them.

Note that all of this work focused on gauge theories with a Lagrangian description, or equivalently Toda CFT correlators with “enough” degeneracy. In particular, we have
avoided the limit $x \to 1$ of 4d $\mathcal{N} = 2$ SQCD, which involves a strongly coupled matter theory instead of hypermultiplets, coupled to a vector multiplet. For $N = 3$ this theory includes $T_3$. The corresponding crossing symmetry on the Toda CFT side consists of the fusion of two simple punctures into a less degenerate operator $\hat{V}_\alpha$. Conformal blocks in this limit are not uniquely characterized by $\alpha$ and external operators, and one needs a label for the continuous multiplicity with which $\hat{V}_\alpha$ appears in the fusion of the two full punctures. These conformal blocks are eigenfunctions of the square of the braiding kernel, and it is tempting to try and diagonalize this kernel. Unfortunately, we only succeeded to tame multiplicities in the simplest discrete versions of the kernel, and could not generalize.

Another direction worth pursuing is to consider S-duality walls in 4d $\mathcal{N} = 2$ theories with gauge groups such as Sp$(N)$ (see for instance [64]). Too little is known at present about braiding kernels of D-type and E-type Toda CFT in order to apply the techniques used here. Understanding whether the U$(N - 1)$ 3d theory found in this paper can be derived through brane constructions may help in generalizing to other gauge groups by orbifolding.

It would also be interesting to check that our gauge theory description of the S-duality wall gives the correct $S^3_b \times S^1$ index, as was done for SU(2) theories in [65–68].
