Abstract

We study the empirical measure associated to a sample of size $n$ and modified by $N$ iterations of the raking-ratio method. This empirical measure is adjusted to match the true probability of sets in a finite partition which changes each step. We establish asymptotic properties of the raking-ratio empirical process indexed by functions as $n \to +\infty$, for $N$ fixed. We study nonasymptotic properties by using a Gaussian approximation which yields uniform Berry-Esseen type bounds depending on $n, N$ and provides estimates of the uniform quadratic risk reduction. A closed-form expression of the limiting covariance matrices is derived as $N \to +\infty$. In the two-way contingency table case the limiting process has a simple explicit formula.

1 Introduction

1.1 The raking-ratio method

In survey analysis, statistics, economics and computer sciences the raking-ratio iterative procedure aims to exploit the knowledge of one or several marginals of a discrete multivariate distribution to fit the data after sampling. Despite many papers from the methodological and algorithmic viewpoint, and chapters in classical textbooks for statisticians, economists or engineers, no probabilistic study is available to take into account that the entries of the algorithm are random and the initial discrete measure is empirical. We intend to fill this gap. Let us first describe the algorithm, usually considered with deterministic entries, then recall the few known results and state the open question to be addressed.

The raking-ratio algorithm. A sample is drawn from a population $P$ for which $k \geq 2$ marginal finite discrete distributions are explicitly known. Initially, each data point has a weight $1/n$. The ratio step of the algorithm consists in computing new weights in such a way that the modified empirical joint distribution has the currently desired marginal. The raking step consists in iterating the correction according to another known marginal law, changing again all the weights. The $k$ margin constraints are usually treated in a periodic order, only one being fulfilled at the same time. The raking-ratio method stops after $N$ iterations with the implicit hope that the previous constraints are still almost satisfied. See Section 1.1 for an elementary numerical example with $k = 2$ and Section 1.4 for notation and mathematical definition of the algorithm.

The limit. This algorithm was called iterative proportions by Deming and Stephan [10] who first introduced it. They showed that the $k$ margins converge
to the desired ones as $N \to +\infty$. They even claimed that if the frequencies of
a multiway contingency table are raked periodically as $N \to +\infty$ they converge
the frequencies minimizing the chi-square distance to the initial frequencies,
under the $k$ margin constraints. Two years later, Stephan [25] observed that it is
wrong and modified the algorithm accordingly to achieve the chi-square distance
minimization. Lewis [18] and Brown [7] studied the case of Bernoulli marginals
from the Shannon entropy minimization viewpoint. When $k = 2$ a two-way
contingency table can be viewed as a matrix. Sinkhorn [22, 23] proved that a
unique doubly stochastic matrix can be obtained from each positive square ma-
trix by alternately normalizing its rows and its columns, which shows that the
algorithm converges in this special case. Finally Ireland and Kullback [16] gen-
eralized previous arguments to rigorously justify that the raking-ratio converges
to the unique projection of the empirical measure in Shannon-Kullback-Leibler
relative entropy on the set of discrete distributions satisfying the $k$ margin con-
straints. From a numerical viewpoint, the rate of convergence of the algorithm
is geometric, see Franklin and Lorentz [15].

Remark A. When minimizing contrasts such as discrimination information, chi-
square distance or likelihood, the minimizers are not explicit due to the non-
linearity of sums of ratios showing up in derivatives. This is why converging
algorithms are used in practice. In the case of the iterative proportions algo-

Theorem Each step is easily and fastly computed. What has been studied concerns
the convergence when the iterations $N \to +\infty$, with $n$ fixed and initial empirical
frequencies treated as deterministic entries. When the sample size $n \to +\infty$,
these entries are close to $P$ itself, which satisfies the marginal constraints, hence
one expects that the number $N$ of iterations necessary to converge is small. We
shall study the $N_0$ first iterations in the statistical setting $n \to +\infty$.

Non explicit bias and variance. The initial values being empirical frequen-
cies the converged solution of the algorithm as $N \to +\infty$ is a joint distributions
fulfilling the marginal requirements that still deviates from the true population
distribution $P$, and moreover in a rather complicated way. The modified empiri-
cal distribution satisfying only the marginal constraint of the current iteration,
there is a permanent bias with respect to other margins, and hence with $P$. The
exact covariance matrix and bias vector of the random weights after $N$ iter-
ations are tedious to compute. For instance, estimates for the variance of cell
probabilities in the case of a two-way contingency table are given by Brackstone
and Rao [6] for $N \leq 4$, Konijn [17] or Choudhry and Lee [8] for $N = 2$. Bankier
[2] proposed a recursive linearization technique providing an estimator of the
asymptotic variance of weights. In Binder and Théberge [4] the variance of the
converged solution requires to calculate weights at each iteration.

Open question. Since exact computations lead to intractable formulas for the
bias and variance of frequencies and statistics as simple as means, an important
open problem is to identify leading terms when $n$ is large compared to $N$. We
derive comprehensive explicit formulas as $n \to +\infty$ for $N \leq N_0$ and $N_0$ fixed,
then for $N \to +\infty$. In order to further analyze the raking ratio method it is
moreover desirable to control simultaneously large classes of statistics and hence
to work at the empirical measure level rather than with the empirical weights or a single statistic only. This is the main motivation for the forthcoming general study of empirical measures indexed by functions and modified through auxiliary information given by partitions.

1.2 Statistical motivation

Representative sample. In a survey analysis context, the raking-ratio method modifies weights of a contingency table built from a sample of size $n$ in order to fit exactly given marginals. Such a strict margin correction is justified when a few properties of the finite population under study are known, like the size of sub-populations. The modified sample frequencies then reflect the marginal structure of the whole population. If the population is large or infinite the information may come from previous and independent statistical inference, from structural properties of the model or from various experts.

Remark B. Making the sample representative of the population is an ad hoc approach based on common sense. The mathematical impact is twofold. On the one hand all statistics are affected by the new weights in terms of bias, variance and limit law so that practitioners may very well be using estimators, tests or confident bands that have lost their usual properties. On the other hand, replacing marginal frequencies with the true ones may smooth sample fluctuations of statistics correlated to them while leaving the uncorrelated ones rather unaffected. These statements will be quantified precisely at Section 2.2.

Remark C. Fitting after sampling is a natural method that has been re-invented many times in various fields, and was probably used long time ago. Depending on the setting it may be viewed as stratification, calibration, iterating proportional fitting, matrix scaling and could be used to deal with missing data. Many fitting methods may be reduced to a raking-ratio type algorithm. We initially called it auxiliary information of partitions as we re-invented it as a special case of the nonparametric partial information problem stated in Section 1.3.

Remark D. An asymptotic approach is no more relevant in survey analysis when the underlying population is rather small. In the small population case, the way the sample is drawn has a so deep impact that it may even become the main topic. A study of calibration methods for finite population can be found in Deville and Särndal [11, 12]. This is beyond the scope of our work.

Quadratic risk reduction. Modifying marginals frequencies of a sample may induce serious drawbacks. One should ask whether or not the estimation risk can be controlled. Typically, a statistic has more bias when sample weights are changed by using raking, calibration or stratification methods after sampling. In the spirit of Remark B, a variance reduction is expected if the statistic of interest is strongly correlated to the $k$ known discrete marginal variables. Now, evaluating the quadratic risk of a specific statistic requires tedious expansions for the bias, variance and correlations of weights, whence the very small $N$ studied in the literature. Likewise, no global risk reduction property has been
Contributions. In this paper we consider classes of empirical means raked \( N \) times, sampled jointly from any population. We derive closed-form expressions of their Gaussian limits and their limiting covariances as \( n \to +\infty \) then \( N \to +\infty \). We also quantify the uniform risk reduction phenomenon and provide sharp statistical estimation tools such as uniform Berry-Esseen type bounds. In particular, a Donsker invariance principle for the raked empirical process provides joint limiting laws for additive statistics built from empirical means, and this can be extended to non linear estimators by applying the delta method, argmax theorems or plug-in approaches as in the classical setting – see [27, 28].

Organization of the paper. In Section 1.3 we relate the raking-ratio problem to nonparametric auxiliary information. The raking-ratio empirical process \( \alpha_n^{(N)}(F) \) is defined in Section 1.4. Usual assumptions on an indexing class \( F \) of functions are given in Section 2.1. In Section 2.2 we state our results for \( \alpha_n^{(N)}(F) \) when the number \( N \) of iterations is fixed. Our main theorem is a nonasymptotic strong approximation bound which yields the uniform central limit theorem with rate as \( n \to +\infty \), as well as a uniform control of the bias and the covariances for fixed \( n \). The approximating Gaussian process is studied in Section 2.3 which establishes the uniform risk reduction phenomenon provided the iterations are stopped properly. In Section 2.4 in the two partitions case we characterize explicitly the limiting process as \( N \to +\infty \). All statements are proved in Sections 3 and 4. The Appendix provides a few examples.

1.3 An auxiliary information viewpoint

Let \( X_1, \ldots, X_n \) be independent random variables with unknown law \( P \) on some measurable space \((\mathcal{X}, \mathcal{A})\). Assumptions like separability or Hausdorff property are not necessary for this space. Let \( \delta_x \) denote the Dirac mass at \( x \in \mathcal{X} \) and consider the empirical measure \( \mathbb{P}_n = n^{-1} \sum_{i=1}^{n} \delta_{X_i} \) on \( \mathcal{A} \).

Auxiliary information. Our interest for the raking-ratio method came while investigating how to exploit various kinds of partial information on \( P \) to make \( \mathbb{P}_n \) closer to \( P \). The auxiliary information paradigm is as follows. Usually what is assumed on \( P \) is formulated in terms of technical or regularity requirements. Sometimes it is relevant to assume that \( P \) satisfies simple properties that could be tested or estimated separately. Consider the following two extreme situations. First, a parametric model provides a tremendous amount of information by specifying \( P = P_\theta \) up to a finite dimensional parameter \( \theta \), so that \( \mathbb{P}_n \) can be replaced with the most likely \( P_{\theta_n}(X_1, \ldots, X_n) \) among the model. Notice that \( \mathbb{P}_n \) is used to minimize the empirical likelihood, but the resulting \( P_{\theta_n}(X_1, \ldots, X_n) \) is of a very different nature, far from the initial and discrete \( \mathbb{P}_n \) thanks to the valuable parametric information. On the opposite, in a purely nonparametric setting the information mainly comes from the sample itself, so that only slight modifications of \( \mathbb{P}_n \) are induced by weak hypotheses on \( P \) – like support, regularity, symmetry, logconcavity, Bayesian model, semi-parametric model, etc. In established as \( n \to +\infty \) and no multivariate or uniform central limit theorem. These results are established at Propositions 4 to 9.
between, we would like to formalize a notion of a priori auxiliary information on \( P \) based on partial but concrete clues to be combined with the knowledge of \( P_n \). Such clues may come from experts, models, former inference, statistical learning or distributed data. A generic situation one can start with is when the probabilities \( P(A_j) \) of a finite number of sets \( A_j \in \mathcal{A} \) are known – which in a parametric setting already determines \( \theta \) then \( P \).

**Information from one partition.** If the \( A_j \) form a finite partition of \( X \) then the auxiliary information coincides with one discrete marginal distribution and a natural nonparametric redesign \( P_n^{(1)} \) of \( P_n \) is the following. Let \( A_1^{(1)}, \ldots, A_{m_1}^{(1)} \subset \mathcal{A} \) be a partition of \( X \) such that \( P(A^{(1)}) = (P(A_1^{(1)}), \ldots, P(A_{m_1}^{(1)})) \) is known. According to Proposition 1 below, the random measure

\[
P_n^{(1)} = \frac{1}{n} \sum_{j=1}^{m_1} P(A_j^{(1)}) \sum_{X_i \in A_j^{(1)}} \delta_{X_i},
\]

(1.1)

satisfies the auxiliary information \( P_n^{(1)}(A_j^{(1)}) = P(A_j^{(1)}) \), for \( 1 \leq j \leq m_1 \), and is the relative entropy projection of \( P_n \) on these marginal constraints. The random ratios in (1.1) induce a bias between \( P_n^{(1)} \) and \( P \). We prove that the bias of \( \alpha_n^{(1)} = \sqrt{n}(P_n^{(1)} - P) \) vanishes uniformly and that the limiting Gaussian process of \( \alpha_n^{(1)} \) has a smaller variance than the \( P \)-Brownian bridge.

**Extension to \( N \) partitions.** If some among the sets \( A_j \) are overlapping then the information comes from several marginal partitions. It is not obvious how to optimally combine these sources of information since there is no explicit modification of \( P_n \) matching simultaneously several finite discrete marginals. In other words there is no closed form expression of the relative entropy projection of \( P_n \) on several margin constraints. An alternative consists in recursively updating the current modification \( P_n^{(N-1)} \) of \( P_n \) onto \( P_n^{(N)} \) according to the next known marginal \( P(A^{(N)}) = (P(A_1^{(N)}), \ldots, P(A_{m_N}^{(N)})) \) exactly as in (1.1) for \( P_n^{(1)} \) from \( P_n^{(0)} = P_n \) and \( P(A^{(1)}) \). This coincides with the Deming and Stephan’s iterative procedure, that is the raking-ratio algorithm, as formalized in Section 1.4.

### 1.4 Information from \( N \) finite partitions

**The raking-ratio empirical measure.** For all \( N \in \mathbb{N} \), let \( m_N \geq 2 \) and \( \mathcal{A}^{(N)} = \{A_1^{(N)}, \ldots, A_{m_N}^{(N)}\} \subset \mathcal{A} \) be a partition of \( X \) for which we are given the auxiliary information \( P(A^{(N)}) = (P(A_1^{(N)}), \ldots, P(A_{m_N}^{(N)})) \) to be exploited. Assume that

\[
p_N = \min_{1 \leq j \leq m_N} P(A_j^{(N)}) > 0, \quad N \in \mathbb{N},
\]

(1.2)

and \( \mathcal{A}^{(N_1)} \neq \mathcal{A}^{(N_2)} \) if \( |N_1 - N_2| = 1 \), otherwise \( \mathcal{A}^{(N_1)} = \mathcal{A}^{(N_2)} \) is allowed. For \( N = 0 \) there is no information and \( m_0 = 1 \), \( A^{(0)} = \{X\} \), \( P(A^{(0)}) = \{1\} \), \( p_0 = 1 \). For any measurable real function \( f \) write \( P_n^{(0)}(f) = P_n(f) = n^{-1} \sum_{i=1}^n f(X_i) \),
\[ P(f) = \int X f dP \] and \( \alpha_n^{(0)}(f) = \sqrt{n}(P_n^{(0)}(f) - P(f)) \). In (1.1) \( P_n^{(1)} \) allocates the random weight \( P(A_j^{(1)})/nP(A_j^{(1)}) \) to each \( X_i \in A_j^{(1)} \). Hence

\[
\mathbb{P}_n^{(1)}(f) = \sum_{i=1}^n \mathbb{P}_n^{(1)}(\{X_i\})f(X_i) = \sum_{j=1}^{m_1} \sum_{X_i \in A_j^{(1)}} \frac{P(A_j^{(1)})}{nP(A_j^{(1)})}f(X_i)
\]

\[ = \sum_{j=1}^{m_1} \frac{P(A_j^{(1)})}{\mathbb{P}_n(A_j^{(1)})} \left( \frac{1}{n} \sum_{X_i \in A_j^{(1)}} f(X_i) \right) = \sum_{j=1}^{m_1} \frac{P(A_j^{(1)})}{\mathbb{P}_n(\mathbb{P}_n^{(0)}(f1_{A_j^{(1)})})} \mathbb{P}_n^{(0)}(f1_{A_j^{(1)})}). \]

Let define recursively, for \( N \in \mathbb{N}_* \), the \( N \)-th raking-ratio empirical measure

\[
\mathbb{P}_n^{(N)}(f) = \sum_{j=1}^{m_N} \frac{P(A_j^{(N)})}{\mathbb{P}_n(\mathbb{P}_n^{(N-1)}(A_j^{(N)}))} \mathbb{P}_n^{(N-1)}(f1_{A_j^{(N)})}), \quad (1.3)
\]

and the \( N \)-th raking-ratio empirical process

\[
\alpha_n^{(N)}(f) = \sqrt{n}(\mathbb{P}_n^{(N)}(f) - P(f)). \quad (1.4)
\]

For \( A \in \mathcal{A} \) we also write \( \alpha_n^{(N)}(A) = \alpha_n^{(N)}(1_A) \). By (1.3) we have for all \( N \in \mathbb{N}_* \)

\[
\mathbb{P}_n^{(N)}(A_j^{(N)}) = P(A_j^{(N)}), \quad \alpha_n^{(N)}(A_j^{(N)}) = 0, \quad 1 \leq j \leq m_N, \quad (1.5)
\]

as desired. Both weights and support \( \{X_1, \ldots, X_n\} \) of the discrete probability measure \( \mathbb{P}_n^{(N)} \) are random since (1.3) also reads

\[
\mathbb{P}_n^{(N)}(\{X_i\}) = \mathbb{P}_n^{(N-1)}(\{X_i\}) \frac{P(A_j^{(N)})}{\mathbb{P}_n^{(N-1)}(A_j^{(N)})}, \quad \text{for } X_i \in A_j^{(N)}. \]

A few more formulas concerning \( \alpha_n^{(N)} \) and \( \mathbb{P}_n^{(N)} \) are derived in Section 3.1

**Iterated Kullback projections.** The random discrete measures \( \mathbb{P}_n^{(1)}, \ldots, \mathbb{P}_n^{(N)} \) are well defined provided that

\[
\min_{1 \leq k \leq N} \min_{1 \leq j \leq m_k} \mathbb{P}_n(A_j^{(k)}) > 0, \quad (1.6)
\]

which almost surely holds for all \( n \) large enough and \( N \) fixed, by (1.2) and the law of large numbers. Given two probability measures \( Q_n \) and \( Q \) supported by \( \{X_1, \ldots, X_n\} \) we define the relative entropy of \( Q_n \) and \( Q \) – see for instance [9] – to be

\[
d_K(Q_n || Q) = \sum_{i=1}^n Q_n(\{X_i\}) \log \left( \frac{Q_n(\{X_i\})}{Q(\{X_i\})} \right). \]

**Proposition 1.** If (1.6) holds then

\[
\mathbb{P}_n^{(N)} = \arg\min \left\{ d_K(\mathbb{P}_n^{(N-1)} || Q) : Q(A^{(N)}) = P(A^{(N)}), \ supp(Q) = \{X_1, \ldots, X_n\} \right\}.
\]
As a consequence, the formula \(1.3\) means that the \(N\)-th iteration \(\mathbb{P}_n^{(N)}\) is the Shannon-Kullback-Leibler projection of \(\mathbb{P}_n^{(N-1)}\) under the constraint \(P(\mathcal{A}^{(N)})\). Therefore the raking-ratio method is an iterated maximum likelihood procedure.

**A mixture of conditional empirical processes.** By introducing, for \(A \in \mathcal{A}\) such that \(P(A) > 0\) and \(\mathbb{P}_n^{(N)}(A) > 0\), the conditional expectations

\[
\mathbb{P}_n^{(N)}(f|A) = \frac{\mathbb{P}_n^{(N)}(f1_A)}{\mathbb{P}_n^{(N)}(A)}, \quad \mathbb{E}(f|A) = \frac{P(f1_A)}{P(A)}, \quad (1.7)
\]

we see that \(1.3\) further reads

\[
\mathbb{P}_n^{(N)}(f) = \sum_{j=1}^{m_N} P(A_j^{(N)})\mathbb{E}_{n}^{(N-1)}(f|A_j^{(N)}), \quad P(f) = \sum_{j=1}^{m_N} P(A_j^{(N)})\mathbb{E}(f|A_j^{(N)}).
\]

Therefore \(1.4\) can also be formulated into

\[
\alpha_n^{(N)}(f) = \sum_{j=1}^{m_N} P(A_j^{(N)})\alpha_{n,j}^{(N-1)}(f),
\]

\[
\alpha_{n,j}^{(N-1)}(f) = \sqrt{n} \left( \mathbb{E}_{n}^{(N-1)}(f|A_j^{(N)}) - \mathbb{E}(f|A_j^{(N)}) \right). \quad (1.8)
\]

Each \(\alpha_{n,j}^{(N-1)}\) is the conditional empirical process of \(\mathbb{P}_{n}^{(N-1)}\) on a set \(A_j^{(N)}\) of the new partition \(\mathcal{A}^{(N)}\). Their mixture with weights \(P(\mathcal{A}^{(N)})\) is \(\alpha_n^{(N)}\). In view of \(1.7\) and \(1.8\) we have to study the consequences of \(1.3\) on \(\mathbb{P}_{n}^{(N-1)}(f1_{A_j^{(N)}})\) and \(\mathbb{E}_{n}^{(N-1)}(f|A_j^{(N)})\) as \(n \to +\infty\), for \(f \neq 1_{A_j^{(N)}}\).

**Bias and variance problem.** The processes \(\alpha_{n,j}^{(N-1)}\) from \(1.8\) are not centered due to the factors \(1/\mathbb{P}_{n}^{(N-1)}(A_j^{(N)})\) in \(1.3\) and \(1.7\). In general it holds

\[
\mathbb{E} \left( \mathbb{E}_{n}^{(N-1)}(f|A) - \mathbb{E}(f|A) \right) = \mathbb{E} \left( \mathbb{P}_{n}^{(N-1)}(f1_A) \left( \frac{1}{\mathbb{P}_{n}^{(N-1)}(A)} - \frac{1}{P(A)} \right) \right) \neq 0,
\]

except for \((A, f) = (A_j^{(N-1)}, 1_{A_j^{(N-1)}})\) hence \(\alpha_n^{(N)}\) is no more centered if \(N \geq 1\). This unavoidable bias is induced by \(1.3\) to globally compensate for the local cancellation of the variance of \(\mathbb{P}_{n}^{(N)}(\mathcal{A}^{(N)}) = P(\mathcal{A}^{(N)})\). The bias tends to spread through \(1.3\) since the information \(P(\mathcal{A}^{(N)})\) is applied to the biased \(\mathbb{P}_{n}^{(N-1)}\) instead of the unbiased \(\mathbb{P}_n\). The variance of \(\mathbb{P}_{n}^{(N)}(f)\) for the step functions \(f = 1_A\) being null if \(A \in \mathcal{A}^{(N)}\) one expects that \(\mathbb{V}(\alpha_n^{(N)}(f)) \leq \mathbb{V}(\alpha_n^{(0)}(f))\) for many more functions \(f\). Our results show that, uniformly over a large class of functions, the bias vanishes asymptotically and the variance decreases, as well as the quadratic risk, thus \(\mathbb{E}((\mathbb{P}_n^{(N)}(f) - P(f))^2) \leq \mathbb{E}((\mathbb{P}_n^{(0)}(f) - P(f))^2)\) for \(n\) large.
2 Main results

2.1 The raking-ratio empirical and Gaussian processes

Let $\mathcal{M}$ denote the set of measurable real valued functions on $(\mathcal{X}, \mathcal{A})$. Consider a class $\mathcal{F} \subset \mathcal{M}$ such that $\sup_{f \in \mathcal{F}} |f| \leq M < +\infty$ and satisfying the pointwise measurability condition often used to avoid measurability problems. Namely, $\lim_{m \to +\infty} f_m(x) = f(x)$ for all $x \in \mathcal{X}$ and $f \in \mathcal{F}$ where $\{f_m\} \subset \mathcal{F}_*$ depends on $f$ and $\mathcal{F}_* \subset \mathcal{F}$ is countable. With no loss of generality also assume that

$$1_{A}f \in \mathcal{F}, \quad A \in A_0^{(N)} = A^{(1)} \cup \ldots \cup A^{(N)}, \quad f \in \mathcal{F}. \quad (2.1)$$

In addition $\mathcal{F}$ is assumed to have either a small uniform entropy, like Vapnik-Chervonenkis classes – for short, VC-classes – or a small $P$-bracketing entropy, like many classes of smooth functions. These entropy conditions are defined below and named (VC) and (BR) respectively. For a probability measure $Q$ on $(\mathcal{X}, \mathcal{A})$ and $f, g \in \mathcal{M}$ define $d_Q^2(f,g) = \int_{\mathcal{X}} (f-g)^2 dQ$. Let $N(\mathcal{F}, \epsilon, d_Q)$ be the minimum number of balls having $d_Q$-radius $\epsilon$ needed to cover $\mathcal{F}$. Let $N_{\epsilon}(\mathcal{F}, \epsilon, d_P)$ be the least number of $\epsilon$-brackets necessary to cover $\mathcal{F}$, of the form $[g_-, g_+] = \{f : g_- \leq f \leq g_+\}$ with $d_P(g_-, g_+) < \epsilon$.

**Hypothesis (VC).** For $c_0 > 0$, $\nu_0 > 0$ it holds $\sup_Q N(\mathcal{F}, \epsilon, d_Q) \leq c_0/\epsilon^{\nu_0}$ where the supremum is taken over all discrete probability measures $Q$ on $(\mathcal{X}, \mathcal{A})$.

**Hypothesis (BR).** For $b_0 > 0$, $r_0 \in (0, 1)$ it holds $N_{\epsilon}(\mathcal{F}, \epsilon, d_P) \leq \exp(b_0^2/\epsilon^{2r_0})$.

If one modifies a class $\mathcal{F}$ satisfying (VC) or (BR) by adding functions necessary to also satisfy the condition (2.1) then (VC) or (BR) still holds with a new constant $c_0$ or $b_0$ respectively. Many properties and examples of VC-classes or classes satisfying (BR) can be found in Pollard [19], Van der Vaart and Wellner [27] or Dudley [14]. Uniform boundedness is the less crucial assumption and could be replaced by a moment condition allowing some truncation arguments, however adding technicalities.

Let $\ell^\infty(\mathcal{F})$ denote the set of real-valued functions bounded on $\mathcal{F}$, endowed with the supremum norm $\| \cdot \|_{\mathcal{F}}$. The raking-ratio empirical process $\alpha_n^{(N)}$ defined at [124] is now denoted $\alpha_n^{(N)}(\mathcal{F}) = \{\alpha_n^{(N)}(f) : f \in \mathcal{F}\}$. Under (VC) or (BR) $\mathcal{F}$ is a $P$-Donsker class – see Sections 2.5.1 and 2.5.2 of [27]. Thus $\alpha_n^{(0)}(\mathcal{F})$ converges weakly in $\ell^\infty(\mathcal{F})$ to the $P$-Brownian bridge $\mathcal{G}$ indexed by $\mathcal{F}$, that we denote $\mathcal{G}(\mathcal{F}) = \{\mathcal{G}(f) : f \in \mathcal{F}\}$. Hence $\mathcal{G}(\mathcal{F})$ is a Gaussian process such that $f \mapsto \mathcal{G}(f)$ is linear and, for any $f, g \in \mathcal{F}$,

$$E(\mathcal{G}(f)) = 0, \quad \text{Cov}(\mathcal{G}(f), \mathcal{G}(g)) = P(fg) - P(f)P(g). \quad (2.2)$$

As for $\alpha_n^{(N)}$ we write $\mathcal{G}^{(0)}(\mathcal{F}) = \mathcal{G}(\mathcal{F})$ and, for short, $\mathcal{G}(A) = \mathcal{G}(1_A)$ if $A \in \mathcal{A}$. Remind [14]. Let us introduce a new centered Gaussian process $\mathcal{G}^{(N)}(\mathcal{F})$ indexed by $\mathcal{F}$ that we call the $N$-th raking-ratio $P$-Brownian bridge and that is
defined recursively, for any \( N \in \mathbb{N} \) and \( f \in \mathcal{F} \), by
\[
\mathcal{G}^{(N)}(f) = \mathcal{G}^{(N-1)}(f) - \sum_{j=1}^{m_N} \mathbb{E}(f|A_j^{(N)})\mathcal{G}^{(N-1)}(A_j^{(N)}).
\] (2.3)

The distribution of \( \mathcal{G}^{(N)} \) is given in Proposition 7. Lastly, the following notation will be useful,
\[
\sigma_j^2 = \mathbb{V}(f(X)) = P(f^2) - P(f)^2, \quad \sigma_F^2 = \sup_{f \in \mathcal{F}} \sigma_f^2.
\] (2.4)

Notice that \( \sigma_F^2 = \mathbb{V}(\alpha_n^{(0)}(f)) = \mathbb{V}(\mathcal{G}^{(0)}(f)) \).

### 2.2 General properties

We now state asymptotic and nonasymptotic properties that always hold after raking \( N_0 \) times. The i.i.d. sequence \( \{X_n\} \) is defined on a probability space \((\Omega, \mathcal{F}, \mathbb{P})\) so that \( \mathbb{P} \) implicitly leads all convergences when \( n \to +\infty \) and \((X, \mathcal{A})\) is endowed with \( P = \mathbb{P}^{X_1} \). For all \( N \leq N_0 \) the information \( P(A^{(N)}) \) satisfies (1.2). Most of the subsequent constants can be bounded by using only \( \mathbb{P}^{X_1} \).

Write \( L(x) = \log(\max(e, x)) \) and define \( \kappa_{N_0} = \prod_{N=1}^{N_0} (1 + M m_N) \).

**Proposition 2.** If \( \mathcal{F} \) satisfies (VC) or (BR) then for all \( N_0 \in \mathbb{N} \) it holds
\[
\limsup_{n \to +\infty} \frac{1}{\sqrt{2L \circ L(n)}} \sup_{0 \leq N \leq N_0} \left\| \alpha_n^{(N)} \right\|_{\mathcal{F}} \leq \kappa_{N_0} \sigma_{\mathcal{F}} \quad \text{a.s.}
\]

**Remark E.** The limiting constant \( \kappa_{N_0} \leq \left( 1 + M/\rho_{(N_0)} \right)^{N_0} \) is large, and possibly largely suboptimal, except for \( N_0 = 0 \) where \( \kappa_0 = 1 \) coincides with the classical law of the iterated logarithm – from which the proposition follows.

The next result shows that the nonasymptotic deviation probability for \( \left\| \alpha_n^{(N)} \right\|_{\mathcal{F}} \) can be controlled by the deviation probability of \( \left\| \alpha_n^{(0)} \right\|_{\mathcal{F}} \) which in turn can be bounded by using Talagrand [26], van der Vaart and Wellner [27] or more recent bounds from empirical processes theory. However, since the partition changes at each step the constants are penalized by factors similar to \( \kappa_{N_0} \) above, involving
\[
P_{N_0} = \prod_{N=1}^{N_0} p_N, \quad M_{N_0} = \prod_{N=1}^{N_0} m_N, \quad S_{N_0} = \sum_{N=1}^{N_0} m_N.
\] (2.6)

**Proposition 3.** If \( \mathcal{F} \) is pointwise measurable, bounded by \( M \) then for any \( N_0 \in \mathbb{N} \), any \( n \in \mathbb{N} \), and any \( \lambda > 0 \) we have
\[
\mathbb{P} \left( \sup_{0 \leq N \leq N_0} \left\| \alpha_n^{(N)} \right\|_{\mathcal{F}} \geq \lambda \right) \leq 2^{N_0} N_0 M_{N_0} \mathbb{P} \left( \left\| \alpha_n^{(0)} \right\|_{\mathcal{F}} \geq \frac{\lambda P_{N_0}}{(1 + M + \lambda/\sqrt{m})^{N_0}} \right) + S_{N_0} (1 - p_{(N_0)})^n.
\]
Under (BR) it holds, for $n > n_0$ and $\lambda_0 < \lambda < D_0 \sqrt{n},$

\[
P \left( \sup_{0 \leq N \leq N_0} \| \alpha_n^{(N)} \|_F \geq \lambda \right) \leq D_1 \exp(-D_2 \lambda^2) + S_{N_0} \left(1 - p(N_0)\right)^{n},
\]

where the positive constants $D_0, D_1, D_2, n_0, \lambda_0$ are defined at \textbf{(3.4)}. Under (VC) it holds, for $n > n_0$ and $\lambda_0 < \lambda < 2M \sqrt{n},$

\[
P \left( \sup_{0 \leq N \leq N_0} \| \alpha_n^{(N)} \|_F \geq \lambda \right) \leq D_3 \lambda^{n_0} \exp(-D_4 \lambda^2) + S_{N_0} \left(1 - p(N_0)\right)^{n},
\]

where the positive constants $D_3, D_4, n_0, \lambda_0$ are defined at \textbf{(3.10)}.

\textbf{Remark F.} Clearly, to avoid drawbacks $N_0$ should be fixed as $n$ increases, and $\mathcal{F}$ limited to the bare necessities for the actual statistical problem. In this case, Proposition \textbf{3} shows that $\| \alpha_n^{(N)} \|_F$ is of order $C \sqrt{\log n}$ with probability less than $1/n^2$ and $C > 0$. Concentration of measure type probability bounds for $\| \alpha_n^{(N)} \|_F = E(\| \alpha_n^{(N)} \|_F)$ are more difficult to handle due to the mixture \textbf{(1.8)} of processes $\alpha_{n,j}^{(N-1)}$ involving unbounded random coefficients.

Our main result is that the raking-ratio empirical processes $\alpha_n^{(0)}, \ldots, \alpha_n^{(N)}$ jointly converge weakly at some explicit rate to the raking-ratio $P$-Brownian bridges $G^{(0)}, \ldots, G^{(N)}$ defined at \textbf{(2.3)} and studied in Section \textbf{2.3}. The $\mathbb{R}^{N_0+1}$-valued version can be stated as follows.

\textbf{Proposition 4.} If $\mathcal{F}$ satisfies (VC) or (BR) then for all $N_0 \in \mathbb{N}$, as $n \to +\infty$ the sequence $(\alpha_n^{(0)}(\mathcal{F}), \ldots, \alpha_n^{(N_0)}(\mathcal{F}))$ converges weakly to $(G^{(0)}(\mathcal{F}), \ldots, G^{(N_0)}(\mathcal{F}))$ on $\ell_\infty(\mathcal{F} \to \mathbb{R}^{N_0+1})$.

By using Berthet and Mason \textbf{3} we further obtain the following upper bound for the speed of Gaussian approximation of $\alpha_n^{(N)}$ in $\| \cdot \|_F$ distance. The powers provided at their Propositions 1 and 2 are $\alpha = 1/(2 + 5\nu_0)$, $\beta = (4 + 5\nu_0)/(4 + 10\nu_0)$ and $\gamma = (1 - r_0)/2r_0$ — they could be slightly improved.

\textbf{Theorem 2.1.} Let $\theta_0 > 0$. If $\mathcal{F}$ satisfies (VC) then write $v_n = (\log n)^\beta / n^\alpha$. If $\mathcal{F}$ satisfies (BR) then write $v_n = 1/(\log n)^\gamma$. In both cases, one can define on the same probability space $(\Omega, \mathcal{F}, \mathbb{P})$ a sequence $\{X_n\}$ of independent random variables with law $P$ and a sequence $\{G_n\}$ of versions of $\mathcal{G}$ satisfying the following property. For any $N_0 \geq 0$ there exists $n_0 \in \mathbb{N}$ and $d_0 > 0$ such that we have, for all $n \geq n_0$,

\[
P \left( \sup_{0 \leq N \leq N_0} \| \alpha_n^{(N)} - G_n^{(N)} \|_F \geq d_0 v_n \right) < \frac{1}{n^{\theta_0}},
\]

where $G_n^{(N)}$ is the version of $G^{(N)}$ derived from $G_n^{(0)} = G_n$ through \textbf{(2.3)}.

\textbf{Remark G.} Applied with $\theta_0 > 1$, Theorem \textbf{2.1} makes the study of weak convergence of functions of $\alpha_n^{(N)}(\mathcal{F})$ easier by substituting $G_n^{(N)}$ to $\alpha_n^{(N)}$ through

\[
\limsup_{n \to +\infty} \frac{1}{v_n} \sup_{0 \leq N \leq N_0} \| \alpha_n^{(N)} - G_n^{(N)} \|_F \leq d_0 < +\infty \quad a.s.
\]
then exploiting the properties induced by \(2.3\) as in Section \(2.3\). For instance the finite dimensional laws of \(G^{(N)}\) are computed explicitly at Proposition \(4\). For nonasymptotic applications, given a class \(F\) of interest it is possible to compute crude bounds for \(n_0\) and \(d_0\) since most constants are left explicit in our proofs as well as in \(3\). Indeed \(d_0\) depends on \(p_{N_0}\) from \(2.5\), on \(P_{N_0}, M_{N_0}, S_{N_0}\) from \(2.5\), on \(\nu_0, c_0, r_0, b_0\) from (VC) or (BR), on \(N_0, M, \theta_0\) and on some universal constants from the literature.

Clearly, Theorem \(2.1\) implies that the speed of weak convergence of \(\alpha_n^{(N)}\) to \(G^{(N)}\) in Lévy-Prokhorov distance \(d_{LP}\) is at least \(d_0 v_n\) — see \(4.11\) and Section 11.3 of \(13\) for a definition of this metric. More deeply, from Theorem \(2.1\) we derive the following rates of uniform convergence for the bias and the variance.

**Proposition 5.** If \(F\) satisfies (VC) or (BR) then for \(N_0 \in \mathbb{N}\) it holds

\[
\limsup_{n \to +\infty} \frac{n}{v_n} \max_{0 \leq N \leq N_0} \sup_{f \in F} \left| \mathbb{E} \left( \hat{P}_n^{(N)}(f) - P(f) \right) \right| \leq d_0,
\]

where \(v_n \to 0\) and \(d_0\) are the same as in Theorem \(2.1\) and

\[
\limsup_{n \to +\infty} \frac{n}{v_n} \sup_{f, g \in F} \left| \mathbb{E} \left( \left( \hat{P}_n^{(N)}(f) - P(f) \right) \left( \hat{P}_n^{(N)}(g) - P(g) \right) \right) - \frac{1}{n} \text{Cov} \left( G^{(N)}(f), G^{(N)}(g) \right) \right| = \limsup_{n \to +\infty} \frac{n}{v_n} \sup_{f, g \in F} \left| \text{Cov} \left( \hat{P}_n^{(N)}(f), \hat{P}_n^{(N)}(g) \right) \right| - \frac{1}{n} \text{Cov} \left( G^{(N)}(f), G^{(N)}(g) \right) \leq \sqrt{\frac{8}{\pi}} d_0 \sigma_F.
\]

By Proposition 5 the bias process \(\mathbb{E}(\alpha_n^{(N)}(f)) = \sqrt{n}(\mathbb{E}(\hat{P}_n^{(N)}(f)) - P(f))\) vanishes at the uniform rate \(1/\sqrt{n}\). The covariance of \(G^{(N)}\) is computed in Section \(2.2\) and the quadratic risk is estimated at Remark I.

A second consequence of Theorem 2.1 is uniform Berry-Esseen type bounds. Let \(\Phi\) denote the distribution function of the centered standardized normal law.

**Proposition 6.** Assume that \(F\) satisfies (VC) or (BR), fix \(N_0 \in \mathbb{N}\) and let \(d_0 > 0, v_n \to 0\) be defined as in Theorem 2.1. If \(F_0 \subset F\) is such that

\[
\sigma_0^2 = \inf \left\{ \mathcal{V} \left( G^{(N)}(f) \right) : f \in F_0, 0 \leq N \leq N_0 \right\} > 0,
\]

then for any \(d_1 > d_0\) there exists \(n_1 \in \mathbb{N}\) such that for all \(n \geq n_1\),

\[
\max_{0 \leq N \leq N_0} \sup_{f \in F_0} \sup_{x \in \mathbb{R}} \mathbb{P} \left( \frac{\hat{P}_n^{(N)}(f) - P(f)}{\sqrt{\mathcal{V} \left( G^{(N)}(f) \right)}} \leq x \right) - \Phi(x) \leq \frac{d_1}{\sqrt{2\pi} \sigma_0} v_n. \tag{2.7}
\]

Let \(\mathcal{L}\) be a collection of real valued Lipschitz functions \(\varphi\) defined on \(\ell_{\infty}(F)\) with Lipschitz constant bounded by \(C_1 < +\infty\) and such that \(\varphi(G^{(N)})\) has a density bounded by \(C_2 < +\infty\) for all \(0 \leq N \leq N_0\). Then for all \(\varphi \in \mathcal{L}, n \geq n_1\),

\[
\max_{0 \leq N \leq N_0} \sup_{\varphi \in \mathcal{L}, x \in \mathbb{R}} \mathbb{P} \left( \varphi(\alpha_n^{(N)}) \leq x \right) - \mathbb{P} \left( \varphi(G^{(N)}) \leq x \right) \leq d_1 C_1 C_2 v_n. \tag{2.8}
\]
In this section we study the covariance structure of $\mathbb{E}$ inside. Let $\mathbb{E}$ be fixed. The following matrix notation is introduced to shorten formulas. The conditions for (2.8) of Proposition 6 are fulfilled if, for example, $\phi(G(F))$ is easily computed. The functions $f$ appearing in Section 3. Whenever the class $F$ is finite, the density of the transform $\phi(G(F))$ of the finite dimensional Gaussian vector $G(F)$ is easily computed. The conditions for (2.8) of Proposition 6 are fulfilled if, for example, all random variables $\phi(G(F))$ can be controlled by discretizing the small entropy class $F$, by bounding their densities then by taking limits accordingly.

2.3 Limiting variance and risk reduction

In this section we study the covariance structure of $G^{(N)}(F)$ from (2.8) for $N$ fixed. The following matrix notation is introduced to shorten formulas. The brackets $[\cdot]$ refer to column vectors built from the partition $A^{(k)}$ appearing inside. Let $V^t$ denote the transpose of a vector $V$. For $k \leq N$ write

$$E[f|A^{(k)}] = (E(f|A^{(k)}_1), \ldots, E(f|A^{(k)}_{m_k}))^t, \quad G[A^{(k)}] = (G(A^{(k)}_1), \ldots, G(A^{(k)}_{m_k}))^t,$$

and, for $l \leq k \leq N$ define the matrix $P_{A^{(k)}|A^{(l)}}$ to be

$$(P_{A^{(k)}|A^{(l)}})_{i,j} = P(A^{(k)}_j|A^{(l)}_i) = \frac{P(A^{(k)}_j \cap A^{(l)}_i)}{P(A^{(l)}_i)}, \quad 1 \leq i \leq m_l, 1 \leq j \leq m_k.$$

Write $I_{d_k}$ the identity matrix $k \times k$. Remind that $\forall(d) = P(f^2) - (P(f))^2$, $P(A^{(k)})^t = P[A^{(k)}]$ and $P(A^{(k)} \cap A^{(k)}_j) = 0$ if $i \neq j$. The covariance matrix of the Gaussian vector $G[A^{(k)}]$ is $\forall(G[A^{(k)}]) = diag(P(A^{(k)})) - P(A^{(k)})^t P(A^{(k)})$. Let $\cdot$ denote a product between a square matrix and a vector. Finally define

$$\Phi_k^{(N)}(f) = E[f|A^{(k)}] + \sum_{1 \leq L \leq N-k, \sum_{k \leq i_1 < i_2 < \ldots < i_L \leq N} (-1)^L P_{A^{(i_1)}|A^{(i)}} P_{A^{(i_2)}|A^{(i_1)}} \cdots P_{A^{(i_L)}|A^{(i_{L-1})}} \cdot E[f|A^{(i_L)}].$$

An explicit expression for $G^{(N)}$ is given in Lemma 3 and the closed form for the covariance function of $G^{(N)}(F)$ is as follows.

**Proposition 7.** For all $N \in \mathbb{N}$ the process $G^{(N)}(F)$ is Gaussian, centered and linear with covariance function defined to be, for $(f,g) \in F^2$,

$$\text{Cov} \left( G^{(N)}(f), G^{(N)}(g) \right) = \text{Cov}(G(f), G(g)) - \sum_{k=1}^N \Phi_k^{(N)}(f)^t \cdot \forall(G[A^{(k)}]) \cdot \Phi_k^{(N)}(g).$$
Remark I. In particular we have \( \sum \limits_{\pi} = \sigma \) (Proposition 8).

**Proposition 8.** For any \( \{f_1, ..., f_m\} \subset \mathcal{F} \) and \( N \in \mathbb{N} \) the covariance matrices \( \Sigma_m^{(N)} = \mathbb{V}((\mathbb{G}^{(N)}(f_1), ..., \mathbb{G}^{(N)}(f_k))) \) are such that \( \Sigma_m^{(0)} - \Sigma_m^{(N)} \) is positive definite.

**Remark I.** In particular we have \( \mathbb{V}((\mathbb{G}^{(N)}(f)) \leq \mathbb{V}((\mathbb{G}^{(0)}(f)) = \sigma_f^2, f \in \mathcal{F} \). The asymptotic risk reduction after raking is quantified by combining Propositions 5 and 8. Given \( \varepsilon > 0 \) and \( 0 < \sigma_0 < \sigma_f \) there exists some \( n_0 = n_0(\varepsilon, \mathcal{F}) \) such that if \( n > n_0 \) then any \( f \in \mathcal{F} \) with initial quadratic risk \( \sigma_f^2/n > \sigma_0/n \) has a new risk, after raking \( N \) times, equal to

\[
\mathbb{E} \left( (\mathbb{P}^{(N)}_n(f) - \mathbb{P}(f))^2 \right) = \frac{\sigma_f^2}{n} (\Delta(f) + e(f)\nu_n),
\]

where \( \nu_n \to 0 \) and \( d_0 \) are as in Theorem 2.1 and

\[
\Delta(f) = \frac{\mathbb{V}(\mathbb{G}^{(N)}(f))}{\sigma_f^2} \in [0, 1],
\]

\[
\sup_{f \in \mathcal{F}, \sigma_f \geq \sigma_0} |e(f)| < (1 + \varepsilon) \sqrt{\frac{8}{\pi}} d_0 \frac{\sigma_f}{\sigma_0},
\]

\[
\mathbb{V} \left( \mathbb{G}^{(N)}(f) \right) = \sigma_f^2 - \sum_{k=1}^{N} \Phi_{k}(N)(f)^t \cdot \mathbb{V} \left( \mathbb{G}[\mathcal{A}(k)] \right) \cdot \Phi_{k}(N)(f),
\] (2.10)

so that the risk is reduced whenever \( \Delta(f) < 1 \) and \( n \) is large enough.

When \( N_1 > N_0 > 0 \) it is not automatically true that the covariance structure of \( \alpha_n^{(N_1)}(\mathcal{F}) \) decreases compared to that of \( \alpha_n^{(N_0)}(\mathcal{F}) \). According to the next statement, a simple sufficient condition is to rake two times along the same cycle of partitions.

**Proposition 9.** Let \( N_0, N_1 \in \mathbb{N} \) be such that \( N_1 \geq 2N_0 \) and

\[
\mathcal{A}^{(N_0-k)} = \mathcal{A}^{(N_1-k)}, \text{ for } 0 \leq k < N_0.
\]

Then it holds \( \mathbb{V}(\mathbb{G}^{(N_1)}(f)) \leq \mathbb{V}(\mathbb{G}^{(N_0)}(f)) \) for all \( f \in \mathcal{F} \) and \( \Sigma_m^{(N_0)} - \Sigma_m^{(N_1)} \) is positive definite for all \( \{f_1, ..., f_m\} \subset \mathcal{F} \).

**Remark I.** In Appendix 2 a counter-example with \( N_1 = N_0 + 1 \) shows that the variance does not decrease for all functions at each iteration. This case is excluded from Proposition 9 since \( N_1 = N_0 + 1 < 2N_0 \) if \( N_0 > 1 \) and, whenever \( N_0 = 1 \) and \( N_1 = 2 \) the requirement \( \mathcal{A}^{(N_0)} = \mathcal{A}^{(N_1)} \) is not allowed.

### 2.4 The case of two marginals

We now consider the original method where \( k \) partitions are raked in a periodic order. Let us focus on the case \( k = 2 \) of the two-way contingency table. The Deming and Stephan algorithm coincides with the Sinkhorn-Knopp algorithm.
for matrix scaling \[24\]. Denote \( \mathcal{A} = \mathcal{A}^{(1)} = \{A_1, \ldots, A_{m_1}\} \) and \( \mathcal{B} = \mathcal{A}^{(2)} = \{B_1, \ldots, B_{m_2}\} \) the two known margins, thus \( \mathcal{A}^{(2m+1)} = \mathcal{A} \) and \( \mathcal{A}^{(2m)} = \mathcal{B} \). Likewise for \( 1 \leq i \leq m_1 \) and \( 1 \leq j \leq m_2 \) rewrite \( (P_{\mathcal{A} \mid \mathcal{B}})_{i,j} = P(A_j|B_i) \), \( (P_{\mathcal{B} \mid \mathcal{A}})_{i,j} = P(B_j|A_i) \) and

\[
G[\mathcal{A}] = (G(A_1), \ldots, G(A_{m_1}))^t, \quad E[f|\mathcal{A}] = (E(f|A_1), \ldots, E(f|A_{m_1}))^t, \\
G[\mathcal{B}] = (G(B_1), \ldots, G(B_{m_2}))^t, \quad E[f|\mathcal{B}] = (E(f|B_1), \ldots, E(f|B_{m_2}))^t.
\]

The matrix \( P_{\mathcal{A} \mid \mathcal{B}} P_{\mathcal{B} \mid \mathcal{A}} \) is \( m_1 \times m_1 \) and \( P_{\mathcal{B} \mid \mathcal{A}} P_{\mathcal{A} \mid \mathcal{B}} \) is \( m_2 \times m_2 \). A sum with a negative upper index is null, a matrix with a negative power is also null, and a square matrix with power zero is the identity matrix. For \( N \in \mathbb{N}_+ \) define

\[
S_{1,\text{even}}^{(N)}(f) = \sum_{k=0}^{N} (P_{\mathcal{B} \mid \mathcal{A}} P_{\mathcal{A} \mid \mathcal{B}})^k \cdot (E[f|\mathcal{A}] - P_{\mathcal{B} \mid \mathcal{A}} \cdot E[f|\mathcal{B}]) \text{ is } m_1 \times 1, \quad (2.11)
\]

\[
S_{2,\text{odd}}^{(N)}(f) = \sum_{k=0}^{N} (P_{\mathcal{A} \mid \mathcal{B}} P_{\mathcal{B} \mid \mathcal{A}})^k \cdot (E[f|\mathcal{B}] - P_{\mathcal{A} \mid \mathcal{B}} \cdot E[f|\mathcal{A}]) \text{ is } m_2 \times 1, \quad (2.12)
\]

\[
S_{1,\text{odd}}^{(N)}(f) = S_{1,\text{even}}^{(N)} + (P_{\mathcal{B} \mid \mathcal{A}} P_{\mathcal{A} \mid \mathcal{B}})^{N+1} \cdot E[f|\mathcal{A}] \text{ is } m_1 \times 1, \quad (2.13)
\]

\[
S_{2,\text{even}}^{(N)}(f) = S_{2,\text{odd}} + (P_{\mathcal{A} \mid \mathcal{B}} P_{\mathcal{B} \mid \mathcal{A}})^{N+1} \cdot E[f|\mathcal{B}] \text{ is } m_2 \times 1. \quad (2.14)
\]

**Proposition 10.** Let \( m \in \mathbb{N} \). We have

\[
G^{(2m)}(f) = G(f) - S_{1,\text{even}}^{(m-1)}(f)^t \cdot G[\mathcal{A}] - S_{2,\text{even}}^{(m-2)}(f)^t \cdot G[\mathcal{B}], \quad (2.15)
\]

\[
G^{(2m+1)}(f) = G(f) - S_{1,\text{odd}}^{(m-1)}(f)^t \cdot G[\mathcal{A}] - S_{2,\text{odd}}^{(m-1)}(f)^t \cdot G[\mathcal{B}]. \quad (2.16)
\]

**Remark K.** The limiting process \( G^{(N)} \) evaluated at \( f \) is then simply \( G(f) \) with a correction depending on the Gaussian vectors \( G[\mathcal{A}] \) and \( G[\mathcal{B}] \) through the two deterministic matrices \( P_{\mathcal{A} \mid \mathcal{B}} \) and \( P_{\mathcal{B} \mid \mathcal{A}} \) carrying the information and operating on the conditional expectation vectors \( E[f|\mathcal{A}] \) and \( E[f|\mathcal{B}] \).

The following assumption simplifies the limits and ensures a geometric rate of convergence for matrices \( S_{l,\text{even}}^{(N)} \) and \( S_{l,\text{odd}}^{(N)} \) as \( N \to +\infty \).

**Hypothesis (ER).** The matrices \( P_{\mathcal{A} \mid \mathcal{B}} P_{\mathcal{B} \mid \mathcal{A}} \) and \( P_{\mathcal{B} \mid \mathcal{A}} P_{\mathcal{A} \mid \mathcal{B}} \) are ergodic.

**Remark L.** Notice that (ER) holds whenever the matrices have strictly positive coefficients. This is true for \( P_{\mathcal{A} \mid \mathcal{B}} P_{\mathcal{B} \mid \mathcal{A}} \) if \( \sum_{j=1}^{m_2} P(A \cap B_j)P(B_j \cap A') > 0 \) for all \( A, A' \in \mathcal{A} \) hence if each pair \( A, A' \in \mathcal{A} \) is intersected by some \( B \in \mathcal{B} \) with positive probability. The latter requirement is for instance met if \( \mathcal{X} = \mathbb{R}^d \), \( P \) has a positive density and the partitions concern two distinct coordinates.

**Proposition 11.** Under (ER) the matrices \( S_{l,\text{even}}^{(N)}(f) \) and \( S_{l,\text{odd}}^{(N)}(f) \) for \( l = 1, 2 \) converge uniformly on \( \mathcal{F} \) to \( S_{l,\text{even}}(f) \) and \( S_{l,\text{odd}}(f) \) satisfying

\[
S_{1,\text{odd}}(f) = S_{1,\text{even}}(f) + P_1[f], \quad S_{2,\text{even}}(f) = S_{2,\text{odd}}(f) + P_2[f],
\]
Remark N. In the case of an auxiliary information reduced to $P \lambda$ of adaptative tests or estimators. Since a two partitions raking procedure. Let $d$ partions $P$ of the limiting process $G$ of the limiting process the probabilities of more overlapping sets are known the above characterization

Remark M. approaches could strengthen the following two remarks.

The matrices $S_{1, \text{even}}(f)$, $S_{2, \text{odd}}(f)$ and scalars $\lambda_1, \lambda_2$ are as in Proposition 11.

**Theorem 2.2.** Under (ER) the sequence $\{G^{(N)}(F)\}$ defined at (2.3) converges almost surely to the centered Gaussian process $G^{(\infty)}(F)$ defined to be

$$G^{(\infty)}(f) = G(f) - S_{1, \text{even}}(f)^t \cdot G[A] - S_{2, \text{odd}}(f)^t \cdot G[B], \quad f \in F.$$  

Moreover we have, for all $N$ large and $c_3 > 0$ depending on $\lambda_1, \lambda_2, P(A), P(B)$,

$$d_{L^P}(G^{(N)}, G^{(\infty)}) \leq c_3 \sqrt{N} \max(\lambda_1, \lambda_2)^{N/2}.$$  

Theorem 2.2 may be viewed as a stochastic counterpart of the deterministic rate obtained by Franklin and Lorentz 15 for the Sinkhorn algorithm. Mixing both approaches could strengthen the following two remarks.

**Remark N.** The matrices $P_{A|B}$, $P_{B|A}$ and the vectors $E[f|A]$, $E[f|B]$ are not known without additional information. They can be estimated uniformly over $F$ as $n \to +\infty$ to evaluate the distribution of $G^{(N)}$ and $G^{(\infty)}$, thus giving access to adaptative tests or estimators. Since $\lambda_1, \lambda_2$ and $c_3$ are related to eigenvalues of $P_{A|B}P_{B|A}$ and $P_{B|A}P_{A|B}$ they can be estimated adaptively at rate $1/\sqrt{n}$ in probability. This in turn provides an evaluation of $d_{L^P}(G^{(N)}, G^{(\infty)})$.

**Remark M.** In the case of an auxiliary information reduced to $P(A), P(B)$ one should use $A = \{A, A'\}$, $B = \{B, B'\}$, estimate the missing $P(A \cap B)$ in $P_{A|B}$, $P_{B|A}$ and the conditional expectations on the four sets, then $S_{1, \text{even}}, S_{2, \text{odd}}$. If the probabilities of more overlapping sets are known the above characterization of the limiting process $G^{(\infty)}(F)$ can be generalized to a recursive raking among $k$ partitions $\{A_j, A'_j\}$ in the same order.

## 3 Proofs of general results

### 3.1 Raking formulas

Write

$$B_{n, N_0} = \left\{ \min_{0 \leq N < N_0} \min_{1 \leq j \leq m_N} \mathbb{P}_n \left( A_j^{(N)} > 0 \right) \right\}, \quad (3.1)$$

and $B_{n, N_0}^c = \Omega \setminus B_{n, N_0}$. By (1.2), the probability that $\alpha_n^{(N)}$ is undefined is

$$P(B_{n, N_0}^c) \leq \sum_{N=1}^{N_0} m_N \left( 1 - p_N \right)^n \leq S_{N_0} \left( 1 - p(N) \right)^n.$$
On $B_{n,N_0}$ we have, by (1.3) and since $A^{(N)}$ is a partition,

\[ \alpha_n^{(N)}(f) = \sqrt{n}(P_n^{(N)}(f) - P(f)) \]

\[ = \sqrt{n} \left( \sum_{j=1}^{m_N} \frac{P(A_j^{(N)})}{P_n^{(N-1)}(A_j^{(N)})} P_n^{(N-1)}(f1_{A_j^{(N)}}) - \sum_{j=1}^{m_N} P(f1_{A_j^{(N)}}) \right) \]

\[ = \sum_{j=1}^{m_N} \left( \frac{P(A_j^{(N)})}{P_n^{(N-1)}(A_j^{(N)})} \alpha_n^{(N-1)}(f1_{A_j^{(N)}}) - \frac{P(f1_{A_j^{(N)}})}{P_n^{(N-1)}(A_j^{(N)})} \alpha_n^{(N-1)}(A_j^{(N)}) \right) \]

\[ = \sum_{j=1}^{m_N} \frac{P(A_j^{(N)})}{P_n^{(N-1)}(A_j^{(N)})} \alpha_n^{(N-1)} \left( (f - E(f|A_j^{(N)}))1_{A_j^{(N)}} \right). \tag{3.2} \]

By (1.7) this implies (1.8) since for any $A \in \mathcal{A}$,

\[ \alpha_n^{(N-1)}(f1_A) - E(f|A)\alpha_n^{(N-1)}(A) = P_n^{(N-1)}(f1_A) - E(f|A)P_n^{(N-1)}(A). \]

Define $A_{(0)}^{(N)} = \{\Omega\}$ and, for $N \geq 1$,

\[ A_{(N)}^{(N)} = \left\{ A : A = A_{(1)}^{(N_1)} \cap A_{(2)}^{(N_2)} \cap \ldots \cap A_{(N)}^{(N)}, j_k \leq m_k, k \leq N \right\}. \tag{3.3} \]

For any $A \in A_{(N)}^{(N)}$, $P_n^{(N)}$ associates to each $X_i \in A$ the weight

\[ \omega_n^{(N)}(A) = \frac{1}{n} \prod_{k=1}^{N} \frac{P(A_{(k)}^{(N)})}{P_n^{(N-1)}(A_{(k)}^{(N)})}. \tag{3.4} \]

The case $N = 1$ yields (1.3). By induction on (1.3), (3.4) and since $A_{(1)}^{(N)}$ is a refined finite partition of $X$, we get

\[ P_n^{(N+1)}(f) = \sum_{j=1}^{m_{N+1}} \frac{P(A_j^{(N+1)})}{P_n^{(N)}(A_j^{(N+1)})} P_n^{(N)}(f1_{A_j^{(N+1)}}) \]

\[ = \sum_{j=1}^{m_{N+1}} \frac{P(A_j^{(N+1)})}{P_n^{(N)}(A_j^{(N+1)})} \sum_{A \in A_{(N)}^{(N)}} \sum_{i=1}^{n} \omega_n^{(N)}(A)f(X_i)1_{A \cap A_j^{(N+1)}}(X_i) \]

\[ = \sum_{i=1}^{n} f(X_i) \sum_{A \in A_{(N)}^{(N)}} \sum_{j=1}^{m_{N+1}} 1_{A \cap A_j^{(N+1)}}(X_i) \omega_n^{(N+1)}(A \cap A_j^{(N+1)}) \]

\[ = \sum_{i=1}^{n} f(X_i) \sum_{A \in A_{(N+1)}^{(N+1)}} 1_A(X_i) \omega_n^{(N+1)}(A). \]
3.2 Proof of Proposition 1

The partition \( A_i^{(N)} \) is defined at (3.3). By using (3.3) it holds, for \( N \geq 1 \),

\[
d_K \left( \frac{P_n^{(N-1)}}{P_n^{(N)}} \right)
= \sum_{i=1}^{n} \frac{P_n^{(N-1)}}{P_n^{(N)}} \left( X_i \right) \log \left( \frac{P_n^{(N-1)}}{P_n^{(N)}} \left( X_i \right) \right)
= \sum_{i=1}^{n} \frac{P_n^{(N-1)}}{P_n^{(N)}} \left( X_i \right) \sum_{j=1}^{m_N} 1_{A_j \cap A_j^{(N)}} \log \left( \frac{\omega_n^{(N-1)}(A)}{\omega_n^{(N)}(A \cap A_j^{(N)})} \right)
= \sum_{j=1}^{m_N} \log \left( \frac{P_n^{(N-1)}(A_j^{(N)})}{P(A_j^{(N)})} \right) \sum_{i=1}^{n} \frac{P_n^{(N-1)}}{P_n^{(N)}} \left( X_i \right) \sum_{j=1}^{m_N} 1_{A_j \cap A_j^{(N)}} \left( X_i \right)
= \sum_{j=1}^{m_N} P_n^{(N-1)}(A_j^{(N)}) \log \left( \frac{P_n^{(N-1)}(A_j^{(N)})}{P(A_j^{(N)})} \right),
\]

since \( A_j^{(N-1)} \) is a partition of \( \mathcal{X} \). Hence the contrast between \( P_n^{(N-1)} \) and \( P_n^{(N)} \) is the same on \( \{X_1, ..., X_n\} \) as on \( A^{(N)} \). Now, by convexity of \( -\log(x) \) it follows, for any probability distribution \( Q \) supported by \( \{X_1, ..., X_n\} \),

\[
d_K \left( \frac{P_n^{(N-1)}}{Q} \right)
= - \sum_{i=1}^{n} \log \left( \frac{Q\left( X_i \right)}{P_n^{(N-1)}\left( X_i \right)} \right) \sum_{j=1}^{m_N} P_n^{(N-1)}\left( X_i \right) 1_{A_j^{(N)}}\left( X_i \right)
= - \sum_{j=1}^{m_N} P_n^{(N-1)}\left( A_j^{(N)} \right) \sum_{i=1}^{n} \frac{P_n^{(N-1)}\left( X_i \right)}{P_n^{(N-1)}\left( A_j^{(N)} \right)} 1_{A_j^{(N)}}\left( X_i \right) \log \left( \frac{Q\left( X_i \right)}{P_n^{(N-1)}\left( X_i \right)} \right)
\geq - \sum_{j=1}^{m_N} P_n^{(N-1)}\left( A_j^{(N)} \right) \log \left( \sum_{i=1}^{n} \frac{Q\left( X_i \right)}{P_n^{(N-1)}\left( A_j^{(N)} \right)} 1_{A_j^{(N)}}\left( X_i \right) \right)
= \sum_{j=1}^{m_N} P_n^{(N-1)}\left( A_j^{(N)} \right) \log \left( \frac{P_n^{(N-1)}\left( A_j^{(N)} \right)}{P\left( A_j^{(N)} \right)} \right) = d_K \left( \frac{P_n^{(N-1)}}{P} \right),
\]

where the final identification relies on (3.3) and \( P_n^{(N)} = P \) on \( A^{(N)} \).

3.3 Proof of Proposition 2

The classical law of the iterated logarithm holds for the empirical process \( \alpha_n^{(0)} \) indexed by \( \mathcal{F} \) under (VC) and (BR). See Alexander [11] in particular Theorem 2.12 for (BR) and Theorem 2.13 based on Theorem 2.8 that uses in its proof the consequence of Lemma 2.7, which is indeed (VC). Namely, for any \( \epsilon > 0 \),
with probability one there exists \( n(\omega) \) such that, for all \( n > n(\omega) \),
\[
    u_n \|p_n^{(0)} - P\|_F < 1 + \varepsilon, \quad u_n = \sqrt{\frac{n}{2\sigma_F^2 L \circ L(n)}},
\]
(3.6)
where \( \sigma_F^2 = \sup_F \forall(f) \leq M^2 \). Let \( 1 \leq N \leq N_0 \). By (1.3) it holds
\[
\begin{align*}
    \mathbb{P}_n^{(N)}(f) - \mathbb{P}_n^{(N-1)}(f) &= \sum_{j=1}^{m_N} \mathbb{P}_n^{(N-1)}(f_{1A^{(N)}_j}) \frac{P(A^{(N)}_j)}{\mathbb{P}_n^{(N-1)}(A^{(N)}_j)} - \sum_{j=1}^{m_N} \mathbb{P}_n^{(N-1)}(f_{1A^{(N)}_j}) \\
    &= \sum_{j=1}^{m_N} \mathbb{P}_n^{(N-1)}(f_{1A^{(N)}_j}) \left(P(A^{(N)}_j) - \mathbb{P}_n^{(N-1)}(A^{(N)}_j)\right).
\end{align*}
\]
Since \( \mathbb{P}_n^{(N)} \) is a probability measure we have \( \|\mathbb{P}_n^{(N)}(f_{1A^{(N)}_j})\|_F \leq M\mathbb{P}_n^{(N)}(A^{(N)}_j) \) hence \( \|\mathbb{P}_n^{(N-1)}(f_{1A^{(N)}_j})\|_F \leq M \) and \( \|\mathbb{P}_n^{(N)}(f) - \mathbb{P}_n^{(N-1)}(f)\| \leq Mm_N\|\mathbb{P}_n^{(N-1)} - P\|_F \).

Also observe that (1.2) combined with the fact that \( A^{(N)} \) is a partition implies \( m_N \leq 1/p_N \) and \( p_N \geq p(0) \). Therefore
\[
\begin{align*}
    u_n \left\|\mathbb{P}_n^{(N)} - P\right\|_F &\leq u_n \left\|\mathbb{P}_n^{(N-1)} - P\right\|_F + u_n \left\|\mathbb{P}_n^{(N)} - \mathbb{P}_n^{(N-1)}\right\|_F \\
    &\leq u_n (1 + Mm_N) \left\|\mathbb{P}_n^{(N-1)} - P\right\|_F \\
    &\leq u_n \kappa_N \left\|\mathbb{P}_n^{(0)} - P\right\|_F,
\end{align*}
\]
where, for \( N > 0 \),
\[
    \kappa_N = \prod_{k=1}^N (1 + Mm_N) \leq \prod_{k=1}^N \left(1 + \frac{M}{p_k}\right) \leq \left(1 + \frac{M}{p(N_0)}\right)^{N_0},
\]
which by (3.6) remains true for \( N = N_0 = 0 \). This proves that, given \( N_0 \in \mathbb{N} \) and for all \( \varepsilon > 0 \),
\[
\limsup_{n \to +\infty} \sqrt{\frac{n}{2L \circ L(n)}} \sup_{0 \leq N \leq N_0} \left\|\mathbb{P}_n^{(N)} - P\right\|_F \leq (1 + \varepsilon)\kappa_N \sigma_F \quad \text{a.s.}
\]
and Proposition 3 follows.

3.4 Proof of Proposition 3

Step 1. We work on \( B_{n,N_0} \) from (3.1), which means that all the probabilities considered below concern events that we implicitly assume to be intersected with \( B_{n,N_0} \). By (1.3) and (3.2) we have, for \( N \geq 1 \),
\[
    \alpha^{(N-1)}_{n,j}(f) = \frac{1}{\mathbb{P}_n^{(N-1)}(A^{(N)}_j)} \mathbb{P}_n^{(N-1)}(f_{1A^{(N)}_j}) \left(f - \mathbb{E}(f|A^{(N)}_j)\right)_{A^{(N)}_j},
\]
with \( |\mathbb{E}(f | A_j^{(N)})| \leq M \), and

\[
\mathbb{P} \left( \left\| \alpha_n^{(N)} \right\|_F \geq \lambda \right) \leq \mathbb{P} \left( \sum_{j=1}^{m_N} P(A_j^{(N)}) \left\| \alpha_{n,j}^{(N-1)} \right\|_F \geq \sum_{j=1}^{m_N} P(A_j^{(N)}) \lambda \right)
\leq \sum_{j=1}^{m_N} \mathbb{P} \left( \left\| \alpha_{n,j}^{(N-1)} \right\|_F \geq \lambda \right).
\]

Each term in the latter sum satisfies, for any positive numbers \( K \leq P(A_j^{(N)}) \) and \( K' \leq P(A_j^{(N)}) - K \),

\[
P \left( \frac{1}{P_n^{(N-1)}(A_j^{(N)})} \left\| \alpha_n^{(N-1)}(f) - \mathbb{E}(f | A_j^{(N)}) \alpha_n^{(N-1)}(A_j^{(N)}) \right\|_F \geq \lambda \right)
\leq P \left( (1 + M) \left\| \alpha_n^{(N-1)} \right\|_F \geq K \lambda \right) + P \left( P_n^{(N-1)}(A_j^{(N)}) \leq K \right)
\leq P \left( \left\| \alpha_n^{(N-1)} \right\|_F \geq \frac{\lambda K}{1 + M} \right) + P \left( \alpha_{n,j}^{(N-1)}(A_j^{(N)}) \leq -K' \sqrt{n} \right)
\leq 2P \left( \left\| \alpha_n^{(N-1)} \right\|_F \geq \frac{\lambda K}{1 + M} \right),
\]

where the last bound holds provided that \( K' \sqrt{n} \geq \lambda K/(1 + M) \). Define

\[
\beta = \frac{1}{1 + \lambda/(1 + M) \sqrt{n}} \in (0, 1), \quad K = \beta p_N, \quad K' = p_N (1 - \beta),
\]

where \( p_N \) is defined in (1.2). Since \( p_N \leq 1/2 \) for any \( N \geq 1 \) it holds \( K' > 0 \) and \( K' \sqrt{n} = \lambda K/(1 + M) \). We have shown that for any \( N \geq 1 \),

\[
P \left( \left\| \alpha_n^{(N)} \right\|_F \geq \lambda \right) \leq 2m_N \mathbb{P} \left( \left\| \alpha_n^{(N-1)} \right\|_F \geq \frac{\lambda \beta p_N}{1 + M} \right).
\]

Applying (3.7) again with \( \lambda \) turned into the smaller \( \lambda \beta p_N / (1 + M) \) then iterating backward from \( N_0 \) we get, for \( P_{N_0} = \prod_{N=1}^{N_0} p_N \) and \( M_{N_0} = \prod_{N=1}^{N_0} m_N \leq 1/P_{N_0} \),

\[
P \left( \left\| \alpha_n^{(N_0)} \right\|_F \geq \lambda \right) \leq 2^{N_0} M_{N_0} \mathbb{P} \left( \left\| \alpha_n^{(0)} \right\|_F \geq \frac{\lambda P_{N_0}}{1 + M + \lambda' \sqrt{n}} \right).
\]

The latter upper bound being increasing with \( N_0 \) we conclude that

\[
P \left( \max_{0 \leq N \leq N_0} \left\| \alpha_n^{(N)} \right\|_F \geq \lambda \right) \leq \sum_{N=1}^{N_0} \mathbb{P} \left( \left\| \alpha_n^{(N)} \right\|_F \geq \lambda \right) \leq N_0 \mathbb{P} \left( \left\| \alpha_n^{(N_0)} \right\|_F \geq \lambda \right).
\]

**Step 2.** By Theorem 2.14.25 of van der Vaart and Wellner [27] or Corollary 2 of [3], for \( n \geq 1, t > 0 \), we have for some universal constants \( D'_1 > 0, D'_2 > 0 \),

\[
P \left( \left\| \alpha_n^{(0)} \right\|_F > D'_1 (\mu_n + t) \right) \leq \exp \left( -D'_2 \min \left( \frac{t^2}{\sigma_n^2}, \frac{t \sqrt{n}}{M} \right) \right).
\]
where, by the last maximal inequality in Theorem 2.14.2 of [27] applied to \( \mathcal{F} \) with envelop function constant to \( M \), it holds

\[
\mu_n = \mathbb{E} \left| \frac{1}{\sqrt{n}} \sum_{i=1}^{n} f(X_i) \right|_{\mathcal{F}} \leq M \int_{0}^{1} \sqrt{1 + \log N_{\mathcal{F}}(\mathcal{G}, M\varepsilon, d_{\mathcal{P}})} d\varepsilon.
\]

Under (BR), we have \( \mu_n < C \) with \( C = M(1 + b_0/(1 - r_0)) \). For \( \lambda_0 = 2D'_1 C \) we get, for any \( n > 0 \) and \( \lambda_0 < \lambda < 2D'_1\sigma_\mathcal{F}^2/\sqrt{n}M \),

\[
\mathbb{P} \left( \|\alpha_n^{(0)}\|_{\mathcal{F}} > \lambda \right) \leq \mathbb{P} \left( \|\alpha_n^{(0)}\|_{\mathcal{F}} > D'_1 \left( \mu_n + \frac{\lambda}{2D'_1} \right) \right) \leq \exp \left( -D'_2\lambda^2 \right),
\]

where \( D'_2 = D'_2/4(D'_1)^2\sigma_\mathcal{F}^2 \). Therefore, according to (3.8), taking

\[
D_0 = \frac{2D'_1\sigma_\mathcal{F}^2}{M}, \quad D_1 = N_02^{N_0}M_{N_0}, \quad D_2 = \frac{D'_2P_{N_0}^2}{(1 + M + D_0)^2N_0},
\]

(3.9) yields \( \mathbb{P}(\max_{0 \leq N \leq N_0}\|\alpha_n^{(N)}\|_{\mathcal{F}} \geq \lambda) \leq D_1 \exp \left( -D_2\lambda^2 \right) \) for \( \lambda_0 < \lambda < D_0\sqrt{M} \).

**Step 3.** By Theorem 2.14.9 in [27], under (VC) there exists a constant \( D(c_0) \) such that, for \( t_0 \) large enough and all \( t \geq t_0 \),

\[
\mathbb{P} \left( \|\alpha_n^{(0)}\|_{\mathcal{F}} \geq t \right) \leq \left( \frac{D(c_0)t}{M\sqrt{v_0}} \right)^{v_0} \exp \left( -\frac{2t^2}{M^2} \right).
\]

Denote \( \lambda_{1,n} \) and \( \lambda_{2,n} \) the two solutions of \( \lambda P_{N_0} = t_0(1 + M + \lambda/\sqrt{n})^{N_0} \). Notice that, for \( n \) large, \( \lambda_{1,n} \) is close to \( t_0(1 + M)^{N_0}/P_{N_0} \), and \( \lambda_{2,n} = O(n^{N_0}/2(N_0 - 1)) \).

Combined with (3.8) it ensues that for some \( n_0, \lambda_0 \) it holds, for all \( n > n_0 \) and \( \lambda_0 < \lambda < 2M\sqrt{n_0} \), \( \mathbb{P}(\max_{0 \leq N \leq N_0}\|\alpha_n^{(N)}\|_{\mathcal{F}} \geq \lambda) \leq D_3\lambda^{v_0}\exp( -D_4\lambda^2) \) where

\[
D_3 = \frac{N_02^{N_0}M_{N_0}D(c_0)P_{N_0}}{(1 + M)^{v_0}N_0}, \quad D_4 = \frac{2P_{N_0}^2}{M^2(3M + 1)^{2N_0}}.
\]

Finally, at each step, add \( S_{N_0} \) \((1 - p_{N_0})^{-n} \) to take \( B_{n,N_0} \) from (3.11) into account.

### 3.5 Proof of Proposition 4 and Theorem 2.1

Theorem 2.1 implies Proposition 4 since the weak convergence on \( (\ell^\infty(\mathcal{F}), \|\cdot\|_{\mathcal{F}}) \) is metrized by the Lévy-Prokhorov distance between \( \alpha_n^{(N)} \) and \( \mathcal{G}_n^{(N)} \) which is

\[
\inf \left\{ \varepsilon > 0 : \mathbb{P}^{\alpha_n^{(N)}}(A) \leq \mathbb{P}^{\mathcal{G}_n^{(N)}}(A^{\varepsilon}) + \varepsilon, \mathbb{P}^{\mathcal{G}_n^{(N)}}(A) \leq \mathbb{P}^{\alpha_n^{(N)}}(A^{\varepsilon}) + \varepsilon \right\} \leq d_0v_n .
\]

(3.11)

To see this, recall that we have \( v_n > 1/n^{\theta_0} \) for \( \theta_0 > 1/2 \) and \( v_n \to 0 \) in Theorem 2.1, remind (1.6) and (3.7) then observe that

\[
\mathbb{P} \left( \alpha_n^{(N)} \in A \right) \leq \mathbb{P} \left( \left\{ \alpha_n^{(N)} \in A \right\} \cap \left\{ \|\alpha_n^{(N)} - \mathcal{G}_n^{(N)}\|_{\mathcal{F}} \leq d_0v_n \right\} \cap B_{n,N_0} \right) + \mathbb{P} \left( \left\{ \|\alpha_n^{(N)} - \mathcal{G}_n^{(N)}\|_{\mathcal{F}} > d_0v_n \right\} \cap B_{n,N_0} \right) + \mathbb{P} \left( B_{n,N_0}^{c} \right)
\]

\[
\leq \mathbb{P}(\mathcal{G}_n^{(N)} \in A^{v_n}) + \frac{1}{n^{\theta_0}} + S_{N_0}(1 - p_{N_0})^{-n},
\]

(3.12)
which obviously remains true by exchanging $\alpha_n^{(N)}$ and $\phi_n^{(N)}$. Since $v_n$ is the slowest sequence as $n \to +\infty$, if $n_0$ satisfies $\nu_{n_0} > 1/n_0^p + S_{n_0} (1 - p(\nu_{n_0}))^{n_0}$ then $v_n > 1/n^p + S_{n_0} (1 - p(\nu_{n_0}))^{n}$ for all $n > n_0$. Whence \((3.11)\).

We next establish Theorem 2.1. Fix $N_0 \in \mathbb{N}$.

Step 1. Let introduce the transforms, for $f \in \mathcal{F}$, $N \geq 1$ and $1 \leq j \leq m_N$,

\[
\phi_{(j,N)}f = \left( f - \mathbb{E} \left( f \mid A_j^{(N)} \right) \right) 1_{A_j^{(N)}},
\]

\[
\phi_{(N)}f = \sum_{j=1}^{m_N} \phi_{(j,N)}f = f - \sum_{j=1}^{m_N} \mathbb{E}(f \mid A_j^{(N)}) 1_{A_j^{(N)}}.
\]

It holds $P(\phi_{(N)}f) = P(\phi_{(j,N)}f) = 0$ and, since $\mathcal{A}^{(N)}$ is a partition of $\mathcal{X}$,

\[
(\phi_{(j,N)}f)(\phi_{(j',N)}g) = 0, \quad 1 \leq j \neq j' \leq m_N. \tag{3.12}
\]

Moreover, the $L_2(P)$ property of conditional expectations yields, with the notation \((2.4)\),

\[
\sigma_{\phi_{(N)}f}^2 = P(f_{(j,N)}^2) \leq \sigma_{\phi_{(N)}f}^2 = P(f_{(N)}^2) = \sum_{j=1}^{m_N} \sigma_{\phi_{(j,N)}f}^2 \leq \sigma_f^2. \tag{3.13}
\]

Next consider the class of backward iterated transforms

\[
\mathcal{F}_{(N)} = \phi_{(1)} \circ \ldots \circ \phi_{(N)}(\mathcal{F}),
\]

\[
\mathcal{H}_{(N)} = \bigcup_{1 \leq k \leq N} \bigcup_{1 \leq j \leq m_k} \phi_{(j,k)} \circ \phi_{(k+1)} \circ \ldots \circ \phi_{(N)}(\mathcal{F}),
\]

where $\phi_{(k+1)} \circ \ldots \circ \phi_{(N)} = id$ if $k = N \geq 1$ and $\mathcal{F}_{(0)} = \mathcal{H}_{(0)} = \mathcal{F}$. Also write $\mathcal{F}_0 = \bigcup_{0 \leq N \leq N_0} \mathcal{F}_{(N)}$ and $\mathcal{H}_0 = \bigcup_{0 \leq N \leq N_0} \mathcal{H}_{(N)}$. By iterating \((3.13)\) it comes $\sigma_{\mathcal{H}_0}^2 \leq \sigma_{\mathcal{F}_0}^2 \leq \sigma_{\mathcal{F}}^2$. We first show that properties of $\mathcal{F}$ transfer to $\mathcal{F}_{(N)}$ and $\mathcal{H}_{(N)}$ for $0 \leq N \leq N_0$ and thus to $\mathcal{F}_0$ and $\mathcal{H}_0$. Remind the constants defined at \((2.6)\).

**Lemma 1.** Assume \((1.2)\). If $\mathcal{F}$ is pointwise measurable and bounded by $M$ then $\mathcal{F}_{(N)}$ and $\mathcal{H}_{(N)}$ (resp. $\mathcal{F}_0$ and $\mathcal{H}_0$) are pointwise measurable and bounded by $(2M)^N/P_N$ (resp. $(2M)^{N_0}/P_{N_0}$). If $(VC)$ (resp. $(BR)$) holds then $\mathcal{F}_0$ and $\mathcal{H}_0$ also satisfies $(VC)$ (resp. $(BR)$) with the same power $\nu_0$ (resp. $r_0$) as $\mathcal{F}$.

**Proof.** If $\mathcal{F}$ is uniformly bounded by $M$ then for $N \leq N_0$ we have

\[
\sup_{\mathcal{F}} \sup_{\mathcal{X}} \left| \phi_{(N)}f \right| = \sup_{\mathcal{F}} \max_{1 \leq j \leq m_N} \sup_{\mathcal{X}} \left| \phi_{(j,N)}f \right| \leq M \left( 1 + \frac{1}{p_N} \right) \leq \frac{2M}{p_N},
\]

thus, by backward induction from $N_0$ to 1, $\mathcal{F}_{(N_0)}$ and $\mathcal{H}_{(N_0)}$ are uniformly bounded by $(2M)^{N_0}/P_N$. It readily follows that $\mathcal{F}_0$ and $\mathcal{H}_0$ are bounded by $(2M)^{N_0}/P_{N_0}$. Assume that $f_k \in \mathcal{F}_*$ converges pointwise on $\mathcal{X}$ to $f \in \mathcal{F}$. From

\[
\lim_{k \to +\infty} 1_{A_j^{(N)}}(X)f_k(X) = 1_{A_j^{(N)}}(X)f(X) \quad \text{and} \quad P(1_{A_j^{(N)}} | f_k |) \leq P(|f_k|) \leq M,
\]
we deduce by dominated convergence that \( \lim_{k \to +\infty} \mathbb{E}(f_k | A_j^{(N)}) = \mathbb{E}(f | A_j^{(N)}) \). Thus \( \phi(j,N) f_k \) converges pointwise to \( \phi(j,N) f \) and \( \phi(j,N) f_k = \sum_{j=1}^{m_N} \phi(j,N) f_k \) to \( \phi(N) f = \sum_{j=1}^{m_N} \phi(j,N) f \). By iterating this reasoning backward from \( N \) to 1 we obtain that \( \mathcal{F}(N) \) and \( \mathcal{H}(N) \) are pointwise measurable, by using the countable classes \( \phi(1) \circ ... \circ \phi(N)(\mathcal{F}_s) \) and \( \bigcup_{1 \leq k \leq N} \bigcup_{1 \leq j \leq m_k} \phi(j,k) \circ \phi(k+1) \circ ... \circ \phi(N)(\mathcal{F}_s) \) respectively. Assume next that \( \mathcal{F} \) satisfies \((VC)\). By (3.12) we have

\[
d^2_Q(\phi(N)f, \phi(N)g) = \int_X \left( \sum_{j=1}^{m_N} (\phi(j,N)f - \phi(j,N)g)^2 \right) dQ
\]

\[
= \sum_{j=1}^{m_N} d^2_Q(\phi(j,N)f, \phi(j,N)g)
\]

\[
= \sum_{j=1}^{m_N} \int_{A_j^{(N)}} (f - g - \mathbb{E}(f - g | A_j^{(N)}))^2 dQ
\]

\[
\leq \sum_{j=1}^{m_N} \int_{A_j^{(N)}} (f - g - (Qf - Qg))^2 dQ
\]

\[
= d^2_Q(f, g) - (Qf - Qg)^2,
\]

thus \( d_Q(f, g) < \varepsilon \) implies \( d^2_Q(\phi(N)f, \phi(N)g) \leq d^2_Q(f, g) < \varepsilon^2 \). If \( \mathcal{F} \) can be covered by \( N(\mathcal{F}, \varepsilon, d_Q) \) balls of \( d_Q \)-radius \( \varepsilon \) centered at some \( g \) then \( \phi(N)(\mathcal{F}) \) can be covered by the same number of balls, centered at the corresponding \( \phi(N)g \) and hence the same number of centers \( \phi(1) \circ ... \circ \phi(N)g \) suffices to cover \( \mathcal{F}(N) \). All the \( \phi(j,k) \circ \phi(k+1) \circ ... \circ \phi(N)g \) are needed to cover \( \mathcal{H}(N) \), that is \( SN(N(\mathcal{F}, \varepsilon, d_Q)) \). This shows that \( \mathcal{F}_0 \) (resp. \( \mathcal{H}_0 \)) obeys \((VC)\) with the same power \( v_0 \) and a constant \( c_0(N_0 + 1) \) (resp. \( c_0 \sum_{N=0}^{N_0} S_N \)). Assume now that \( \mathcal{F} \) satisfies \((BR)\). If \( g_- \leq f \leq g_+ \) then we have

\[
h_{(j,N)}^- = 1_{A_j^{(N)}} g_+ - 1_{A_j^{(N)}} E \left( g_+ | A_j^{(N)} \right)
\]

\[
\leq \phi(j,N) f \leq 1_{A_j^{(N)}} g_+ - 1_{A_j^{(N)}} E \left( g_- | A_j^{(N)} \right) = h_{(j,N)}^+,
\]

and the \( L_2(P) \)-size of the new bracket \([h_{(j,N)}^-, h_{(j,N)}^+]\) is

\[
d^P_P(h_{(j,N)}^-, h_{(j,N)}^+) = \int_{A_j^{(N)}} (g_+ - g_- + E(g_+ - g_- | A_j^{(N)}))^2 dP
\]

\[
= P(1_{A_j^{(N)}} (g_+ - g_-)^2) + P(A_j^{(N)}) E(g_+ - g_- | A_j^{(N)})^2
\]

\[
+ 2 E(g_+ - g_- | A_j^{(N)}) P(1_{A_j^{(N)}} (g_+ - g_-)).
\]

If \( d_P(g_+, g_-) < \varepsilon \) the Hölder inequality yields \( P(1_{A_j^{(N)}} (g_+ - g_-)) \leq \varepsilon \sqrt{P(A_j^{(N)})} \) and \( E(g_+ - g_- | A_j^{(N)}) \leq \varepsilon / \sqrt{P(A_j^{(N)})} \) hence

\[
d^P_P(h_{(j,N)}^-, h_{(j,N)}^+) \leq P(1_{A_j^{(N)}} (g_+ - g_-)^2) + 3\varepsilon^2,
\]

23
so that \( \phi(N)f = \sum_{j=1}^{m_N} \phi(j,N)f \in [h^-(N), h^+(N)] \) where \( h^\pm(N) = \sum_{j=1}^{m_N} h^\pm(j,N) \) satisfies

\[
d_p^2(h^-(N), h^+(N)) = \sum_{j=1}^{m_N} d_p^2(h^-(j,N), h^+(j,N)) \leq d_p^2(g-, g_+) + 3m_N \varepsilon^2 \leq 4m_N \varepsilon^2.
\]

It ensues \( N_1[F(\varepsilon, d_p)] \leq N_1[F, \varepsilon/2\sqrt{m_N}, d_p] \) and \( N_1(F(N), \varepsilon, d_p) \leq N_1(F, \varepsilon/2N \sqrt{M_N}, d_p) \). To cover \( \phi_{(j,k)} \circ \phi_{(k+1)} \circ ... \circ \phi(N)(F) \) one needs at most \( m_kN_1[F, \varepsilon/2N_0 \sqrt{M_N}, d_p] \) brackets. We have proved that

\[
N_1(F_0, \varepsilon, d_p) \leq (N_0 + 1)N_1(F, \varepsilon/2N_0 \sqrt{M_N}, d_p),
\]

\[
N_1(H_0, \varepsilon, d_p) \leq S_{N_0}N_1(F, \varepsilon/2N_0 \sqrt{M_N}, d_p).
\]

Therefore \( F_0, H_0 \) satisfy (BR) with power \( r_0 \) and constant \( 2^{r_0}M^{r_0}b_0 \) \( \square \).

**Step 2.** By (3.2) we have

\[
\alpha_n^{(N)}(f) = \sum_{j=1}^{m_N} \frac{P(A_j^{(N)})}{p_n^{(N-1)}(A_j^{(N)})} \alpha_n^{(N-1)}(\phi(j,N)f) = \alpha_n^{(N-1)}(\phi(N)f) + \Gamma_n^{(N)}(f),
\]

(3.14)

\[
\Gamma_n^{(N)}(f) = \sum_{j=1}^{m_N} q_n(j, N) \alpha_n^{(N-1)}(\phi(j,N)f), \quad q_n(j, N) = \frac{P(A_j^{(N)})}{p_n^{(N-1)}(A_j^{(N)})} - 1.
\]

Under the convention that \( \phi_{(N+1)} \circ \phi(N) = id \), iterating (3.14) leads to

\[
\alpha_n^{(N)}(f) = \alpha_n^{(0)}(\phi_{(1)} \circ ... \circ \phi(N)f) + F_n^{(N)}(f),
\]

\[
F_n^{(N)}(f) = \sum_{k=1}^{N} \Gamma_n^{(k)}(\phi_{(k+1)} \circ ... \circ \phi(N)f).
\]

Clearly the terms \( \Gamma_n^{(k)} \) carry out some bias and variance distortion. However the following lemma states that \( \alpha_n^{(0)}(F(N)) \) is the main contribution to \( \alpha_n^{(N)}(F) \) and \( F_n^{(N)}(F) \) is an error process.

**Lemma 2.** Consider the sequence \( v_n \) defined at Theorem 2.7. If \( F \) satisfies (VC) or (BR) then there exists \( C_0 < +\infty \) such that we almost surely have, for all \( n \) large enough, \( \max_{0 \leq j \leq N_0} \| F_n^{(N)} \|_F \leq C_0L \circ L(n) / \sqrt{n} \). Moreover, for any \( \zeta > 0 \) and \( \theta > 0 \) there exists \( n_3(\zeta, \theta) \) such that we have, for all \( n > n_3(\zeta, \theta) \),

\[
\mathbb{P} \left( \max_{0 \leq j \leq N_0} \| F_n^{(N)} \|_F > \zeta v_n \right) \leq \frac{1}{2n^\theta}.
\]

**Proof.** (i) Let us apply Proposition 2 to \( F \) and, thanks to Lemma 1 to \( H_0 \) and \( H(N) \). So for all \( \varepsilon > 0 \) we have for all \( n \) large enough,

\[
\max_{1 \leq j \leq N} \max_{1 \leq j \leq m_N} \left| \alpha_n^{(N-1)}(A_j^{(N)}) \right| \leq \sigma_{F(N)} \sqrt{2L \circ L(n)} (1 + \varepsilon).
\]

24
The following statements are almost surely true, for all $n$ large enough. On the one hand, for $\varepsilon = \sqrt{2} - 1 > 0$,\[\max_{1 \leq N \leq N_0} \max_{1 \leq j \leq m_N} |a_n^{(N-1)}(A_j^{(N)})| \leq b_n = 2\sigma_F\kappa_{N_0}\sqrt{L \circ \tilde{L}(n)}. \quad (3.15)\]

On the other hand, having $\sigma_{\mathcal{H}_0} \leq \sigma_F$ by (3.13),\[\max_{1 \leq N \leq N_0} \max_{1 \leq k \leq N_1 \leq j \leq m_k} |a_n^{(k-1)}(\phi_{(j,k)} \circ \phi_{(k+1)} \circ \ldots \circ \phi_{(N)} f)| \leq \max_{1 \leq k \leq N_0} \left\| a_n^{(k-1)} \right\|_{\mathcal{H}_0} \leq b_n. \quad (3.13)\]

By (3.15), $q_n(j, N) = 1/\left(1+ a_n^{(N-1)}(A_j^{(N)})/P(A_j^{(N)}) \sqrt{m}\right) - 1$ satisfies\[\max_{1 \leq N \leq N_0} \max_{1 \leq j \leq m_N} |q_n(j, N)| \frac{\sqrt{n}}{b_n} P(N_0) \leq 2, \quad (3.16)\]

which implies\[\left\| f_n^{(N)} \right\|_F \leq \sum_{k=1}^N \max_{1 \leq j \leq m_k} |q_n(j, k)| \sum_{j=1}^{m_k} a_n^{(k-1)}(\phi_{(j,k)} \circ \phi_{(k+1)} \circ \ldots \circ \phi_{(N)} f), \quad (3.17)\]

The almost sure result then holds with $C_0 = 8\sigma_F^2 \kappa_{N_0}^2 S_{N_0}/P(N_0)$.

(ii) We now work on the event $B_{n, N_0}$ of (3.3). There obviously exists $n_1$ such that if $n > n_1$ then $S_{N_0}(1 - P(N_0))^{n/4} \leq 1/n^\theta$. We can also find $\kappa > 0$ so small that $n^{2\kappa}/\sqrt{n} = o(v_n)$ as $n \to +\infty$. Therefore, whatever $\zeta > 0$ there exists $n_2(\kappa, S_{N_0}, \zeta, F, P)$ such that $v_n > 2S_{N_0}n^{2\kappa}/P(N_0)\sqrt{m}$ for any $n \geq n_2$. Choosing $n \geq \max(n_1, n_2)$ we deduce as for (3.16) and (3.17) that\[P \left( \max_{0 \leq N \leq N_0} \left\| f_n^{(N)} \right\|_F > \zeta v_n \right) \leq \ldots \leq P \left( \max_{1 \leq N \leq N_0} \max_{1 \leq j \leq m_N} |q_n(j, N)| > \frac{2n^\kappa}{P(N_0)\sqrt{n}} \right) + P \left( \max_{1 \leq N \leq N_0} \left\| a_n^{(N-1)} \right\|_{\mathcal{H}_0} > n^\kappa \right) \leq 2P \left( \max_{1 \leq N \leq N_0} \left\| a_n^{(N-1)} \right\|_{\mathcal{H}_0} > n^\kappa \right) \quad .\]

By Proposition 8 we see that under (VC) or (BR) the latter probability can be made less than $1/8n^6$ for any $n > n_3(\zeta, \theta)$ and $n_3(\zeta, \theta)$ large enough. Clearly $n_3(\zeta, \theta)$ depends on $\zeta, \theta, n_1, n_2$ and on the entropy of $\mathcal{H}_0$ thus all constants in Lemma 1 and Proposition 8 are involved. ✷

**Step 3.** Fix $\theta > 0$. By Lemma 1 we can apply Propositions 1 and 2 of Berthet and Mason 8 to $F_0$, which ensures the following Gaussian approximation. For
some constant $c_0(\mathcal{F}_0, P) > 0$ and $n_\theta(\mathcal{F}_0, P) > 0$ we can build on a probability space $(\Omega, \mathcal{T}, \mathbb{P})$ a version of the sequence $\{X_n\}$ of independent random variables with law $P$ and a sequence $\{G_n^{(0)}\}$ of coupling versions of $G^{(0)}$ in such a way that, for all $n \geq n_\theta(\mathcal{F}_0, P)$,

$$
P \left( \left\| \alpha_n^{(0)} - G_n^{(0)} \right\|_{\mathcal{F}_0} > c_\theta(\mathcal{F}_0, P)v_n \right) \leq \frac{1}{2^n \eta}.
$$

(3.18)

Keep in mind that constants $n_\theta$ and $c_0$ only depend on the entropy of $\mathcal{F}_0$ through the constants $M, c_0, v_0, b_0, r_0$. By choosing $\theta > 1$, $d_\theta > c_\theta(\mathcal{F}_0, P)$ then applying Borel-Cantelli lemma to (3.18), it almost surely holds, for all $n$ large enough,

$$
\left\| \alpha_n^{(0)} - G_n^{(0)} \right\|_{\mathcal{F}_0} < d_\theta v_n.
$$

(3.19)

**Step 4.** Let $\theta_0 > 0$. We work under the event $B_{n, N_0}$ of (3.18) with a probability at least $1 - 1/4n^d_\theta$ provided that $n > n_1$. The process $G^{(0)}$ being linear on $\mathcal{F}$ we see that the recursive definition (2.3) applied to the version $G_n^{(0)}$ of $G^{(0)}$ reads

$$
G_n^{(N)}(f) = G_n^{(N-1)}(\phi(N)f).
$$

This combined with (3.14) readily gives

$$
\max_{1 \leq N \leq N_0} \left\| \alpha_n^{(N)} - G_n^{(N)} \right\|_{\mathcal{F}}
= \max_{1 \leq N \leq N_0} \left\| \alpha_n^{(N-1)}(\phi(N)f) - G_n^{(N-1)}(\phi(N)f) + \Gamma_n^{(N)}(f) \right\|_{\mathcal{F}}
\leq \max_{0 \leq N \leq N_0} \left\| F_n^{(N)} \right\|_{\mathcal{F}}.
$$

(3.20)

Remind that $v_n > L(n)/\sqrt{n}$ and Lemma 2 holds. By (3.19) and (3.20) we almost surely have, for all $n$ large enough and $d_0 = 2d_\theta$,

$$
\max_{1 \leq N \leq N_0} \left\| \alpha_n^{(N)} - G_n^{(N)} \right\|_{\mathcal{F}} \leq d_\theta v_n + C_0 \frac{L \circ L(n)}{\sqrt{n}} \leq d_0 v_n.
$$

By Lemmas 1 and 2 (3.18) and (3.20), for $n_0 > \max(n_1, n_3(\zeta, \theta_0), n_\theta(\mathcal{F}_0, P))$ and $d_0 > c_\theta(\mathcal{F}_0, P) + \zeta$ we have, for all $n \geq n_0$,

$$
P \left( \max_{1 \leq N \leq N_0} \left\| \alpha_n^{(N)} - G_n^{(N)} \right\|_{\mathcal{F}} > d_0 v_n \right) \leq \frac{1}{2^n \eta^2} + P \left( \max_{0 \leq N \leq N_0} \left\| F_n^{(N)} \right\|_{\mathcal{F}} > \zeta v_n \right) \leq \frac{1}{n^2 \eta^2}.
$$

To conclude observe that the parameters $N_0, M, M_{N_0}, S_{N_0}, P_{N_0}, P(\mathcal{N}_0), \theta_0, v_0, c_0, r_0, b_0$ have been used at one or several steps to finally define $n_0$ and $d_0$.

### 3.6 Proof of Proposition 5

Theorem 2 implies, for $f \in \mathcal{F}$,

$$
P_n^{(N)}(f) - P(f) = \frac{1}{\sqrt{n}} G_n^{(N)}(f) + \frac{1}{\sqrt{n}} \mathbb{P}_n^{(N)}(f),
$$

(3.21)
where $G^{(N)}_n$ is a sequence of versions of the centered Gaussian process $G^{(N)}$ from \cite{23} and the random sequence $r^{(N)}_n = \|R^{(N)}_n\|_F$ satisfies
\[
\begin{align*}
  r^{(N)}_n &\leq \|G^{(N)}_n\|_F + \|\alpha^{(N)}_n\|_F \leq \|G^{(N)}_n\|_F + 2M\sqrt{n}, \\
  \lim_{n \to +\infty} \frac{r^{(N)}_n}{\|G^{(N)}_n\|_F} &\leq d_0 \text{ a.s.}
\end{align*}
\]
We have to be a little careful with the expectation, variance and covariance of the coupling error process $R^{(N)}_n$.

**Step 1.** Since $G^{(N)}_n(f)$ is centered the bias is controlled by
\[
\begin{align*}
  \sup_{f \in F} \frac{\sqrt{n}}{v_n} \left| \mathbb{E} \left( \mathbb{P}^{(N)}_n(f) \right) - P(f) \right| &= \sup_{f \in F} \left| \frac{1}{v_n} \mathbb{E} \left( \mathbb{R}^{(N)}_n(f) \right) \right| \leq \mathbb{E} \left( \frac{r^{(N)}_n}{v_n} \right). \tag{3.22}
\end{align*}
\]
Write $a_n = \sqrt{K \log n}$ where $K > 0$ and $\theta_0 > 1$ from Theorem 2.1 can be chosen as large as needed. Then, for $\theta > 1$, $\varepsilon > 0$ and $k \in \mathbb{N}^*$ consider the events
\[
\begin{align*}
  A_n &= \left\{ r^{(N)}_n \leq (d_0 + \varepsilon)v_n \right\}, \quad B_n = \left\{ \|G^{(N)}_n\|_F \leq a_n \right\}, \\
  C_{n,k} &= \left\{ \theta^{k-1}a_n < \|G^{(N)}_n\|_F \leq \theta^k a_n \right\}.
\end{align*}
\]
By Theorem 2.1 $\mathbb{P}(A_n^c) < 1/n^{\theta_0}$ and $v_n > a_n/\sqrt{n}$ for all $n$ large enough, hence
\[
\begin{align*}
  \frac{1}{v_n} \mathbb{E} \left( r^{(N)}_n \right) &= \mathbb{E} \left( \frac{r^{(N)}_n}{v_n} 1_{A_n} \right) + \mathbb{E} \left( \frac{r^{(N)}_n}{v_n} 1_{A_n^c \cap B_n} \right) + \mathbb{E} \left( \frac{r^{(N)}_n}{v_n} 1_{A_n^c \cap B_n^c} \right) \\
  &\leq d_0 + \varepsilon + \frac{a_n + 2M\sqrt{n}}{v_n} \mathbb{P}(A_n^c) + \mathbb{E} \left( \frac{r^{(N)}_n}{v_n} 1_{B_n^c} \right) \\
  &\leq d_0 + 2\varepsilon + \sum_{k=1}^{+\infty} \mathbb{E} \left( \frac{r^{(N)}_n}{v_n} 1_{C_{n,k}} \right).
\end{align*}
\]
By Propositions 7 and 8, $G^{(N)}(f)$ is a centered Gaussian process indexed by $F$ such that, under (VC) or (BR), it holds
\[
\begin{align*}
  \mathbb{E} \left( \|G^{(N)}\|_F \right) < +\infty, \quad \sup_{f \in F} \mathbb{V}(G^{(N)}(f)) &\leq \sigma_F^2 < +\infty, \\
  \mathbb{E} \left( \|G^{(N)}\|_F^2 \right) &\leq C_F^2 = \sigma_F^2 + \mathbb{E} \left( \|G^{(N)}\|_F \right)^2 < +\infty. \tag{3.23}
\end{align*}
\]
Thus, by Borell’s inequality – see Appendix A.2 of \cite{27} – for any version $G^{(N)}_n$ of $G^{(N)}$, we have
\[
\begin{align*}
  \mathbb{P} \left( \|G^{(N)}_n\|_F > \lambda \right) &\leq 2\exp \left( -\frac{\lambda^2}{8C_F^2} \right). \tag{3.24}
\end{align*}
\]
Therefore we have, since \( \theta > 1 \) and \( v_n > 4M/\sqrt{n} > 2a_n/n \) for \( n \) large enough,

\[
\mathbb{E}\left( \frac{r_n^{(N)}}{v_n} 1_{C_{n,k}} \right) \leq \frac{\theta^k a_n + 2M\sqrt{n}}{v_n} \mathbb{P}(C_{n,k}) \leq \frac{\theta^k n}{v_n} \mathbb{P}\left( \left\| \mathbb{G}_n^{(N)} \right\|_F > \theta^{-1} a_n \right) \\
\leq 2\theta^k n \exp\left( -\frac{(\theta^{-1} a_n)^2}{8C_F^2} \right),
\]

and the following series is converging to an arbitrarily small sum,

\[
\sum_{k=1}^{+\infty} \mathbb{E}\left( \frac{r_n^{(N)}}{v_n} 1_{C_{n,k}} \right) \leq 2n \exp\left( -\frac{a_n^2}{8C_F^2} \right) \sum_{k=1}^{+\infty} \theta^k \exp\left( -\frac{\theta^2(k-1) - 1}{8C_F^2} a_n^2 \right) \\
\leq n \exp\left( -\frac{K \log n}{8C_F^2} \right) \sum_{k=1}^{+\infty} 2\theta^k \exp\left( -\theta^2(k-1) \right) \leq \frac{1}{n^\delta},
\]

where \( \delta < K/8C_F^2 - 1 \). It follows that (3.22) is ultimately bounded by \( d_0 \).

**Step 2.** Starting from (3.21) and the bias and variance decomposition, the quadratic risk is in turn controlled by

\[
\mathbb{E}\left( (\mathbb{P}_n^{(N)}(f) - P(f))^2 \right) - \frac{1}{n} \mathbb{V} \left( \mathbb{G}^{(N)}(f) \right) \\
= \left| \mathbb{E}\left( \mathbb{P}_n^{(N)}(f) - P(f) \right)^2 \right| + \frac{1}{n} \mathbb{V} \left( \mathbb{G}^{(N)}(f) \right) + \frac{2}{n} \mathbb{C}_n \left( \mathbb{G}_n^{(N)}(f), \mathbb{R}_n^{(N)}(f) \right).
\]

(i) By Step 1, the first right-hand term is the squared bias, of order \( d_0^2 v_n^2/n \).

Concerning the second right-hand term in (3.25), we bound \( \mathbb{E}(\mathbb{R}_n^{(N)}(f))^2 \). Fix \( \varepsilon > 0 \) and assume that \( n \) is large enough for the following statements. By setting \( s_n^{(N)} = (r_n^{(N)})^2 \) then using \( v_n > a_n/\sqrt{n} \), \( a_n = K \log n < \sqrt{n} \) we get, for \( \theta_0 = 2 \),

\[
\frac{1}{v_n} \sup_{f \in \mathcal{F}} \mathbb{E}\left( \mathbb{R}_n^{(N)}(f)^2 \right) \leq \mathbb{E}\left( \frac{s_n^{(N)}}{v_n^2} 1_{A_n} \right) + \mathbb{E}\left( \frac{s_n^{(N)}}{v_n^2} 1_{A_n \cap B_n} \right) + \mathbb{E}\left( \frac{s_n^{(N)}}{v_n^2} 1_{A_n \cap B_n^c} \right) \\
\leq (d_0 + \varepsilon)^2 + \left( \frac{a_n + 2M\sqrt{n}}{v_n} \right)^2 \mathbb{P}(A_n^c) + \mathbb{E}\left( \frac{s_n^{(N)}}{v_n^2} 1_{C_{n,k}} \right) \\
\leq (d_0 + 2\varepsilon)^2 + \sum_{k=1}^{+\infty} \theta^{2k} \frac{n^2}{v_n^2} \mathbb{P}\left( \left\| \mathbb{G}_n^{(N)} \right\|_F > \theta^{-1} a_n \right) \leq (d_0 + 4\varepsilon)^2,
\]

where the series is equal to its first term \( n^2 \exp\left( -\frac{a_n^2}{8C_F^2} \right) \) times a convergent series, by using (3.21) as for Step 1 with \( K > 16C_F^2 \). We have shown that

\[
\limsup_{n \to +\infty} \frac{1}{v_n^2} \sup_{f \in \mathcal{F}} \mathbb{V} \left( \mathbb{R}_n^{(N)}(f) \right) \leq \limsup_{n \to +\infty} \frac{1}{v_n^2} \mathbb{E}\left( s_n^{(N)} \right) \leq d_0^2.
\]

(3.26)
(ii) Concerning the covariance term in (3.25) it holds
\[
\frac{1}{v_n} \left| \text{Cov} \left( G_n^{(N)}(f), B_n^{(N)}(f) \right) \right| = \frac{1}{v_n} \left| E \left( G_n^{(N)}(f) B_n^{(N)}(f) \right) \right| \\
\leq \frac{1}{v_n} E \left( \left| G_n^{(N)}(f) \right| r_n^{(N)} \right) \\
= T_{A_n}(f) + T_{A_n \cap B_n}(f) + T_{A_n \cap B_n^c}(f),
\]
where \( T_D(f) = E(1_D | G_n^{(N)}(f)| r_n^{(N)}/v_n) \) for \( D \in \{ A_n, A_n \cap B_n, A_n \cap B_n^c \} \). We have, by Proposition 7 and 8,
\[
T_{A_n}(f) \leq E \left( \left| G_n^{(N)}(f) \right| (d_0 + \varepsilon)1_{A_n} \right) \\
= (d_0 + \varepsilon) \sqrt{\frac{v_n}{2\pi}} E(\mathcal{N}(0,1)) \leq \sqrt{\frac{2}{\pi}} (d_0 + \varepsilon)\sigma_f.
\]

By using again \( P(A_n^c) < 1/n^2 \) we see that
\[
T_{A_n \cap B_n}(f) \leq E \left( a_n \left( \frac{2M \sqrt{n} + a_n}{v_n} \right) 1_{A_n \cap B_n} \right) \leq a_n \left( \frac{3M \sqrt{n}}{v_n} \right) \frac{1}{n^2} \leq \varepsilon.
\]
Lastly, for \( g_n^{(N)} = \left\| G_n^{(N)} \right\|_{\mathcal{F}}, K \) large and all \( n \) large enough it holds, by (3.23) and (3.24),
\[
T_{A_n \cap B_n^c}(f) \leq E \left( g_n^{(N)} \left( \frac{2M \sqrt{n} + g_n^{(N)}}{v_n} \right) 1_{B_n^c} \right) \\
= \sum_{k=1}^{+\infty} E \left( g_n^{(N)} \left( \frac{2M \sqrt{n} + g_n^{(N)}}{v_n} \right) 1_{C_n, k} \right) \\
\leq \sum_{k=1}^{+\infty} \theta^{2k} a_n^2 n P \left( \left\| G_n^{(N)} \right\|_{\mathcal{F}} > \theta^{k-1} a_n \right) \leq \varepsilon.
\]
The above upper bounds imply, by (3.25), (3.26) and (2.3),
\[
\limsup_{n \to +\infty} \sup_{f \in \mathcal{F}} \frac{n}{v_n} \left| E \left( (\mathbb{P}^{(N)}_n(f) - P(f))^2 \right) - \frac{1}{n} \sqrt{\left( G^{(N)}(f) \right) \left( G^{(N)}(f) \right) } \right| \leq \sqrt{\frac{8}{\pi}} d_0 \sigma_f.
\]
**Step 3.** Let extend Step 2 to the covariance. By Step 1 we have, for all \( n \) large,
\[
\left| \text{Cov} \left( \mathbb{P}^{(N)}_n(f), \mathbb{P}^{(N)}_n(g) \right) - E \left( \left( \mathbb{P}^{(N)}_n(f) - P(f) \right) \left( \mathbb{P}^{(N)}_n(g) - P(g) \right) \right) \right| \\
= \left| \left( E(\mathbb{P}^{(N)}_n(f)) - P(f) \right) \left( E(\mathbb{P}^{(N)}_n(g)) - P(g) \right) \right| < d_0^2 \frac{v_n^2}{n}.
\]

29
Now, by the upper bounds computed at (i) and (ii) of Step 2,

\[
\left|\mathbb{E}\left((P_n^{(N)}(f) - P(f))(P_n^{(N)}(g) - P(g))\right) - \frac{1}{n}\text{Cov}\left(G^{(N)}(f), G^{(N)}(g)\right)\right|
\leq \frac{1}{n}\mathbb{E}\left(|G_n^{(N)}(f)R_n^{(N)}(g)|\right) + \frac{1}{n}\mathbb{E}\left(|G_n^{(N)}(g)R_n^{(N)}(f)|\right)
\leq \frac{2}{n}\sup_{f \in \mathcal{F}}\mathbb{E}\left(|G_n^{(N)}(f)|^2\right) + \frac{1}{n}\mathbb{E}\left(s_{n}^{(N)}\right)
\leq \frac{2}{n}(d_0 + \varepsilon)\sigma_\mathcal{F}\sqrt{\frac{2}{\pi}v_n} + \frac{1}{n}(d_0 + \varepsilon)^2 v_n^2.
\]

### 3.7 Proof of Proposition 6

Fix \(N_0 \in \mathbb{N}\). Let apply Theorem 2.1 with \(\theta_0 = 2\), from which we also use \(n_0\), \(d_0\) and \(v_n\). We have, for all \(0 \leq N \leq N_0\), \(\varphi \in \mathcal{L}\), \(x \in \mathbb{R}\) and \(n \geq n_0\),

\[
\mathbb{P}\left(\varphi(\alpha_n^{(N)}) \leq x\right) \leq \frac{1}{n^2} + \mathbb{P}\left(\left\{\varphi(\alpha_n^{(N)}) \leq x\right\} \cap \left\{\|\alpha_n^{(N)} - G_n^{(N)}\|_\mathcal{F} < d_0v_n\right\}\right)
\leq \frac{1}{n^2} + \mathbb{P}\left(\varphi(G_n^{(N)}) \leq x + d_0C_1v_n\right)
\leq \frac{1}{n^2} + \mathbb{P}\left(\varphi(G_n^{(N)}) \leq x\right) + d_0C_1C_2v_n,
\]

and

\[
\mathbb{P}\left(\varphi(G_n^{(N)}) \leq x - d_0C_1v_n\right)
\leq \frac{1}{n^2} + \mathbb{P}\left(\left\{\varphi(G_n^{(N)}) \leq x - d_0C_1v_n\right\} \cap \left\{\|\alpha_n^{(N)} - G_n^{(N)}\|_\mathcal{F} < d_0v_n\right\}\right)
\leq \frac{1}{n^2} + \mathbb{P}\left(\varphi(\alpha_n^{(N)}) \leq \varphi(G_n^{(N)}) + d_0C_1v_n \leq x\right),
\]

so that

\[
\mathbb{P}\left(\varphi(\alpha_n^{(N)}) \leq x\right) \geq \mathbb{P}\left(\varphi(G_n^{(N)}) \leq x\right) - d_0C_1C_2v_n - \frac{1}{n^2}.
\]

This establishes the second statement of Proposition 6 provided \(d_1 > d_0\) and \(n \geq n_1 \geq n_0\) where \(n_1\) is large enough to have \((d_1 - d_0C_1C_2)v_n > n^{-2}\). The first statement coincides with the special case \(\mathcal{L} = \{\varphi_f : f \in \mathcal{F}_0\}\) where \(\varphi_f(g) = g(f)\) are pointwise projectors and we then have a Lipschitz constant \(C_1 = 1\) whereas \(\varphi_f(G_n^{(N)}) = G_n^{(N)}(f)\) has a Gaussian density bounded by

\[
\frac{1}{\sqrt{2\pi\text{Var}(G_n^{(N)}(f))}} \leq C_2 = \frac{1}{\sqrt{2\pi\sigma_0}} < +\infty.
\]

30
4 Proofs concerning the limiting process

4.1 Proof of Proposition \[\text{7}\]

Step 1. Let us first relate \[\mathcal{G}^{(N)}(\mathcal{F})\] from \[\text{(2.8)}\] to \[\mathcal{G}(\mathcal{F}) = \mathcal{G}^{(0)}(\mathcal{F})\] from \[\text{(2.2)}\] by means of the vectors \(\Phi_k^{(N)}(f)\) introduced at \[\text{(2.9)}\] before Proposition \[\text{7}\].

**Lemma 3.** For all \(N \in \mathbb{N}^*\) and \(f \in \mathcal{F}\) it holds

\[
\mathcal{G}^{(N)}(f) = \mathcal{G}(f) - \sum_{k=1}^{N} \Phi_k^{(N)}(f)^t \cdot \mathcal{G} \left[ A^{(k)} \right].
\]

**Proof.** The formula is true for \(N = 0\). Assume that it is the case for \(N \geq 0\). Recall that sets \(A \in \mathcal{A}_{1(0)}\) from \(\text{(1.9)}\) are identified to \(f = 1_A\). By \(\text{(2.3)}\),

\[
\mathcal{G}^{(N+1)}(f) = \mathcal{G}^{(N)}(f) - \mathbb{E} \left[ f \mid A^{(N+1)} \right]^t \cdot \mathcal{G} \left[ A^{(N+1)} \right] \\
= \mathcal{G}(f) - \sum_{k=1}^{N} \Phi_k^{(N)}(f)^t \cdot \mathcal{G} \left[ A^{(k)} \right] \\
- \sum_{j=1}^{m_{N+1}} \mathbb{E} (f \mid A_j^{(N+1)}) \left( \mathcal{G}(A_j^{(N+1)}) - \sum_{k=1}^{N} \Phi_k^{(N)}(A_j^{(N+1)})^t \cdot \mathcal{G} \left[ A^{(k)} \right] \right) \\
= \mathcal{G}(f) - \mathbb{E} \left[ f \mid A^{(N+1)} \right]^t \cdot \mathcal{G} \left[ A^{(N+1)} \right] \\
- \sum_{k=1}^{N} \left[ \Phi_k^{(N)}(f) - \Phi_k^{(N)}(A^{(N+1)}) \cdot \mathbb{E}[f \mid A^{(N+1)}] \right]^t \cdot \mathcal{G} \left[ A^{(k)} \right],
\]

where the \(m_k \times m_{N+1}\) matrix \(\Phi_k^{(N)}[A^{(N+1)}] = (\Phi_k^{(N)}(A_1^{(N+1)}), \ldots, \Phi_k^{(N)}(A_{m_{N+1}}^{(N+1)}))\) satisfies

\[
\sum_{j=1}^{m_{N+1}} \mathbb{E} (f \mid A_j^{(N+1)}) \Phi_k^{(N)}(A_j^{(N+1)})^t = \left[ \Phi_k^{(N)}[A^{(N+1)}] \cdot \mathbb{E}[f \mid A^{(N+1)}] \right]^t.
\]

Now observe that \(\Phi_k^{(N+1)}(f) = \mathbb{E}[f \mid A^{(N+1)}]\) by the definition of \(\Phi_k^{(N+1)}\) given by \(\text{(2.9)}\) when \(k = N + 1\). It remains to show that

\[
\Phi_k^{(N)}(f) - \Phi_k^{(N)}(A^{(N+1)}) \cdot \mathbb{E}[f \mid A^{(N+1)}] = \Phi_k^{(N+1)}(f).
\]

For \(1 \leq k \leq N\) and \(1 \leq j \leq m_{N+1}\) we have

\[
\Phi_k^{(N)}(A_j^{(N+1)}) = \mathbb{E} \left[ A_j^{(N+1)} \mid A^{(k)} \right] + \\
\sum_{\substack{1 \leq L \leq N-k \leq L \leq N \atop k < l_1 < \ldots < l_L \leq N}} (-1)^L \mathbb{P}[A_{l_1}] \mathbb{P}[A_{l_2}] \mathbb{P}[A_{l_3}] \cdots \mathbb{P}[A_{l_{L-1}}] \cdot \mathbb{E} \left[ A_j^{(N+1)} \mid A^{(l_L)} \right],
\]

\[
|A_{l_{L-1}}| A^{(l_L)}]
\]

|A_{l_{L-1}}| A^{(l_L)}],
\]

\[
31
\]
where, for \( l = k, k + 1, \ldots, N \) the vector

\[
\mathbb{E}\left[ A_j^{(N+1)} | A^{(l)} \right] = \left( \frac{P(A_j^{(N+1)} \cap A_1^{(l)})}{P(A_1^{(l)})}, \ldots, \frac{P(A_j^{(N+1)} \cap A_m^{(l)})}{P(A_m^{(l)})} \right)^t,
\]

is also the \( j \)-th column of \( \mathbf{P}_{A^{(N+1)}|A^{(l)}} \). Therefore, by turning \( L \) into \( L' = L + 1 \),

\[
- \Phi_k^{(N)} \left[ A^{(N+1)} \right] \cdot \mathbb{E} \left[ f | A^{(N+1)} \right]
= - \sum_{j=1}^{m_{N+1}} \mathbb{E}(f | A_j^{(N+1)}) \Phi_k^{(N)}(A_j^{(N+1)})
= - \sum_{j=1}^{m_{N+1}} \mathbb{E}(f | A_j^{(N+1)}) \mathbb{E} \left[ A_j^{(N+1)} | A^{(k)} \right]
+ \sum_{j=1}^{m_{N+1}} \mathbb{E}(f | A_j^{(N+1)}) \sum_{k_1 < \cdots < k_L \leq N} (-1)^L \mathbf{P}_{A^{(l_1)}|A^{(k)}} \cdots \mathbf{P}_{A^{(l_L)}|A^{(k)}} \cdot \mathbb{E} \left[ A_j^{(N+1)} | A^{(l_L)} \right]
= (-1)^L \mathbf{P}_{A^{(N+1)}|A^{(k)}} \mathbb{E} \left[ f | A^{(N+1)} \right]
+ \sum_{1 \leq l' \leq N+1-k \leq l_1 < \cdots < l_L = N+1} (-1)^L \mathbf{P}_{A^{(l_1)}|A^{(k)}} \cdots \mathbf{P}_{A^{(l_L)}|A^{(k)}} \cdot \mathbb{E} \left[ f | A^{(l_L)} \right],
\]

where all terms are different from those in

\[
\Phi_k^{(N)}(f) = \mathbb{E} \left[ f | A^{(k)} \right] + \sum_{1 \leq l' \leq N+1-k \leq l_1 < \cdots < l_L < N+1} (-1)^L \mathbf{P}_{A^{(l_1)}|A^{(k)}} \cdots \mathbf{P}_{A^{(l_L)}|A^{(k)}} \cdot \mathbb{E} \left[ f | A^{(l_L)} \right].
\]

Having collected all terms of \( \Phi_k^{(N)}(f) \) in (4.9), this establishes (4.11). The proof is completed by induction. \( \square \)

The functions \( \Phi_k^{(N)} \) and the process \( \mathbb{G} \) are linear, hence Lemma 3 implies that \( \mathbb{G}^{(N)} \) is a linear process. Moreover \( \mathbb{G}(f) \) and \( \mathbb{G}[A^{(k)}] \) being centered Gaussian, Lemma 3 proves that \( \mathbb{G}^{(N)}(f) \) is a centered Gaussian random variable.

**Step 2.** To compute the covariance of \( \mathbb{G}^{(N)}(\mathcal{F}) \) we need the following properties. Recall that \( \mathbf{P}_{A^{(k)}|A^{(k)}} = \text{Id}_{m_k} \) is the identity matrix of \( \mathbb{R}^{m_k} \).

**Lemma 4.** For \( 1 \leq k, l \leq N \) and \( f \in \mathcal{F} \) we have

\[
\text{Cov} \left( \mathbb{G}[A^{(k)}], \mathbb{G}(f) \right) = \mathbb{V} \left( \mathbb{G}[A^{(k)}] \right) \cdot \mathbb{E}[f | A^{(k)}], \quad (4.2)
\]

\[
\text{Cov} \left( \mathbb{G}[A^{(k)}], \mathbb{G}[A^{(l)}] \right) = \mathbb{V} \left( \mathbb{G}[A^{(k)}] \right) \mathbf{P}_{A^{(l)}|A^{(k)}}, \quad (4.3)
\]

\[
\Phi_k^{(N)}(f) = \mathbb{E} \left[ f | A^{(k)} \right] - \sum_{k \leq l \leq N} \mathbf{P}_{A^{(l)}|A^{(k)}} \cdot \Phi_l^{(N)}(f). \quad (4.4)
\]

32
Proof. The $j$-th coordinate of the vector $\mathbb{V}(G[A^{(k)}]) \cdot \mathbb{E}[f \mid A^{(k)}]$ is
\[
P(A_j^{(k)})(1 - P(A_j^{(k)}))\mathbb{E}(f \mid A_j^{(k)}) - \sum_{j \neq i \leq m_k} P(A_i^{(k)})P(A_j^{(k)})\mathbb{E}(f \mid A_i^{(k)})
\]
\[
= \mathbb{E}(1_{A_j^{(k)}}f) - P(A_j^{(k)}) \sum_{1 \leq i \leq m_k} \mathbb{E}(1_{A_i^{(k)}}f)
\]
\[
= \text{Cov} \left( G(A_j^{(k)}), G(f) \right).
\]
Likewise the $(i, j)$-th coordinate of the matrix $\mathbb{V}(G[A^{(k)}]) \cdot \mathbb{P}_{A^{(l)}|A^{(k)}}$ is
\[
P(A_i^{(k)})(1 - P(A_i^{(k)}))P(A_j^{(l)} | A_i^{(k)}) - \sum_{j \neq m \leq m_k} P(A_i^{(k)})P(A_m^{(k)})P(A_j^{(l)} | A_m^{(k)})
\]
\[
= P(A_j^{(l)} \cap A_i^{(k)}) - P(A_i^{(k)}) \sum_{1 \leq m \leq m_k} P(A_j^{(l)} \cap A_m^{(k)})
\]
\[
= \text{Cov} \left( G(A_i^{(k)}), G(A_j^{(l)}) \right).
\]
By the definition \((2.9)\) of the vectors $\Phi_i^{(N)}(f)$ we get
\[
\sum_{k \leq l \leq N} \mathbb{P}_{A^{(l)}|A^{(k)}} \cdot \Phi_i^{(N)}(f)
\]
\[
= \sum_{k \leq l \leq N} \mathbb{P}_{A^{(l)}|A^{(k)}} \cdot \mathbb{E} \left[ f \mid A^{(l)} \right]
\]
\[
+ \sum_{k \leq l \leq N-1 \leq l \leq N-1} (-1)^{L} \mathbb{P}_{A^{(l)}|A^{(k)}} \mathbb{P}_{A^{(l_1)}|A^{(l)}} \cdots \mathbb{P}_{A^{(l_{L-1})}|A^{(l_{L-1})}} \cdot \mathbb{E} \left[ f \mid A^{(l_{L})} \right]
\]
\[
= \sum_{1 \leq L \leq N-k} (-1)^{L+1} \mathbb{P}_{A^{(l_1)}|A^{(k)}} \cdots \mathbb{P}_{A^{(l_{L-1})}|A^{(l_{L-1})}} \cdot \mathbb{E} \left[ f \mid A^{(l_{L})} \right]
\]
\[
= \mathbb{E} \left[ f \mid A^{(k)} \right] - \Phi_k^{(N)}(f),
\]
which yields \((4.4)\). □

**Step 3.** Let us first compute the variance of $G^{(N)}(f)$. By Lemma \[6\] we have
\[
\mathbb{V} \left( G^{(N)}(f) \right) - \mathbb{V} \left( G(f) \right)
\]
\[
= \sum_{k=1}^{N} \Phi_k^{(N)}(f)^t \cdot \mathbb{V} \left( G[A^{(k)}] \right) - \Phi_k^{(N)}(f)^t \cdot \mathbb{V} \left( G[A^{(k)}] \right) - \Phi_k^{(N)}(f)^t \cdot \text{Cov} \left( G[A^{(k)}], G(f) \right)
\]
\[
+ 2 \sum_{1 \leq k < l \leq N} \Phi_k^{(N)}(f)^t \cdot \text{Cov} \left( G[A^{(k)}], G[A^{(l)}] \right) \cdot \Phi_l^{(N)}(f),
\]

hence Lemma \[6\] gives, through \((4.2)\) and \((4.3)\),
\[
\mathbb{V} \left( G^{(N)}(f) \right) - \mathbb{V} \left( G(f) \right) = \sum_{k=1}^{N} \Phi_k^{(N)}(f)^t \cdot \mathbb{V} \left( G[A^{(k)}] \right) \cdot \Psi_k^{(N)}(f),
\]
where, by (4.4),
\[ \Psi_k^{(N)}(f) = \Phi_k^{(N)}(f) - 2E \left[ f \mid A^{(k)} \right] + 2 \sum_{k < l \leq N} P_{A^{(l)} \mid A^{(k)}} \cdot \Phi_l^{(N)}(f) = -\Phi_k^{(N)}(f). \] (4.5)

The formula (2.10) is proved. It extends to the covariance since, by Lemma 3,
\[ \text{Cov}(G^{(N)}(f), G^{(N)}(g)) - \text{Cov}(G(f), G(g)) = \frac{1}{2} (\Upsilon_N(f, g) - 2\Gamma_N(f, g)) + \frac{1}{2} (\Upsilon_N(g, f) - 2\Gamma_N(g, f)), \]
where, by (4.2) and (4.3) again,
\[ \Upsilon_N(f, g) = \sum_{1 \leq k \leq N} \Phi_k^{(N)}(f)^t \cdot \mathbb{V} \left( G[A^{(k)}] \right) \cdot P_{A^{(l)} \mid A^{(k)}} \cdot \Phi_l^{(N)}(g), \]
\[ \Gamma_N(f, g) = \sum_{i=1}^N \Phi_k^{(N)}(f)^t \cdot \mathbb{V} \left( G[A^{(k)}] \right) \cdot E \left[ g \mid A^{(k)} \right]. \]

By replacing \( \Psi_k^{(N)}(g) \) with \( -\Phi_k^{(N)}(g) \) according to (4.5), we obtain
\[ \frac{1}{2} (\Upsilon_N(f, g) - 2\Gamma_N(f, g)) = -\frac{1}{2} \sum_{k=1}^N \Phi_k^{(N)}(f)^t \cdot \mathbb{V} \left( G[A^{(k)}] \right) \cdot \Phi_k^{(N)}(g), \]
which is symmetric in \( f \) and \( g \). The covariance formula of Proposition 7 is proved.

### 4.2 Proof of Propositions 8 and 9
Since \( \mathbb{V} \left( G[A^{(k)}] \right) \) is semi-definite positive, for all \( 1 \leq k \leq N \) and \( f, g \in \mathcal{F} \) we have
\[ \Phi_k^{(N)}(f)^t \cdot \mathbb{V}(G[A^{(k)}]) \cdot \Phi_k^{(N)}(f) \geq 0, \]
and the variance part (4.10) of Proposition 8 follows from Proposition 7. For any \( m \in \mathbb{N}_+, (f_1, ..., f_m) \in \mathcal{F}^m \) and \( u \in \mathbb{R}^m \), it further holds, by Proposition 7 again,
\[ u^t \left( \Sigma_m^{(0)} - \Sigma_m^{(N)} \right) u = \sum_{1 \leq i, j \leq m} u_i u_j \left( \text{Cov}(G(f_i), G(f_j)) - \text{Cov}(G^{(N)}(f_i), G^{(N)}(f_j)) \right) \]
\[ = \sum_{k=1}^N \sum_{1 \leq i, j \leq m} \left( u_i \Phi_k^{(N)}(f_i) \right)^t \cdot \mathbb{V} \left( G[A^{(k)}] \right) \cdot \left( u_j \Phi_k^{(N)}(f_j) \right) \]
\[ = \sum_{k=1}^N \left( \sum_{1 \leq i \leq m} u_i \Phi_k^{(N)}(f_i) \right)^t \cdot \mathbb{V} \left( G[A^{(k)}] \right) \cdot \left( \sum_{1 \leq j \leq m} u_j \Phi_k^{(N)}(f_j) \right) \geq 0. \]
Under the wrapping hypothesis of Proposition 7 we have
\[ \Phi^{(N_0)}_{N_0-k} = \Phi^{(N_1)}_{N_1-k}, \quad 0 \leq k < N_0, \]
since the corresponding (2.9) only involves \( A^{(N_0-k)} = A^{(N_1-k)} \) for 0 \( \leq k < N_0 \). Assuming moreover \( N_1 \geq 2N_0 \) we get, by Proposition 7
\[ \forall \left( G^{(N_0)}(f) \right) - \forall \left( G^{(N_1)}(f) \right) \]
\[ = \sum_{k=1}^{N_1} \Phi^{(N_1)}_{k}(f)^t \cdot \forall \left( G[A^{(k)}] \right) \cdot \Phi^{(N_1)}_{k}(f) - \sum_{k=1}^{N_0} \Phi^{(N_0)}_{k}(f)^t \cdot \forall \left( G[A^{(k)}] \right) \cdot \Phi^{(N_0)}_{k}(f) \]
\[ = \sum_{k=N_0+1}^{N_1-N_0} \Phi^{(N_1)}_{k}(f)^t \cdot \forall \left( G[A^{(k)}] \right) \cdot \Phi^{(N_1)}_{k}(f) \geq 0, \]
and, for \( m \in \mathbb{N}_+ \), \( f_1, ..., f_m \) \( \in \mathcal{F}^m \) and \( u \in \mathbb{R}^m \),
\[ u^t \cdot \left( \sum_{m}^{(N_0)} - \sum_{m}^{(N_1)} \right) \cdot u \]
\[ = u^t \cdot \left( \sum_{m}^{(0)} - \sum_{m}^{(N_1)} - \sum_{m}^{(0)} - \sum_{m}^{(N_0)} \right) \cdot u \]
\[ = \sum_{k=N_0+1}^{N_1-N_0} \left( \sum_{1 \leq j \leq m} u_j \Phi^{(N)}_{k}(f_j) \right) \cdot t \cdot \forall \left( G[A^{(k)}] \right) \cdot \left( \sum_{1 \leq j \leq m} u_j \Phi^{(N)}_{k}(f_j) \right) \geq 0. \]

### 4.3 Proof of Proposition 10

We show the result by double induction. For \( m = 0 \) we have \( G^{(0)}(f) = G(f) \) and, by (2.9), \( G^{(1)}(f) = G(f) - \mathbb{E}[f | A]^t \cdot G[A] \). Assume that (2.13) and (2.14) are true for \( m \in \mathbb{N} \). For \( m+1 \) we have, by the raking ratio transform (2.3),
\[ G^{(2m+2)}(f) = G^{(2m+1)}(f) - \mathbb{E}[f | B]^t \cdot G^{(2m+1)}[B], \]
\[ G^{(2m+3)}(f) = G^{(2m+2)}(f) - \mathbb{E}[f | A]^t \cdot G^{(2m+2)}[A]. \]

For \( 1 \leq j \leq m_2 \) and \( f = 1_{B_j} \) we get, by (2.10), (2.11), (2.12), (2.13) and (2.14),
\[ G^{(2m+1)}(B_j) \]
\[ = G(B_j) - S^{(m-1)}_{1,\text{odd}}(1_{B_j})^t \cdot G[A] - S^{(m-1)}_{2,\text{odd}}(1_{B_j})^t \cdot G[B] \]
\[ = G(B_j) - \left( \sum_{k=0}^{m-1} (P_{A|B}P_{B|A})^k \cdot (\mathbb{E}[1_{B_j} | B] - P_{A|B} \cdot \mathbb{E}[1_{B_j} | A]) \right)^t \cdot G[B] \]
\[ - \left( \sum_{k=0}^{m-1} (P_{B|A}P_{A|B})^k \cdot (\mathbb{E}[1_{B_j} | A] - P_{B|A} \cdot \mathbb{E}[1_{B_j} | B]) + (P_{B|A}P_{A|B})^m \cdot \mathbb{E}[1_{B_j} | A] \right) \cdot G[A], \]
where $\mathbb{E}[1_{B_j}|A]$ is the $j$-th column of $P_{B_j|A}$ and $\mathbb{E}[1_{B_j}|B]$ is the $j$-th unit vector of $\mathbb{R}^{m_2}$. Therefore

$$G^{(2m+1)}[B]$$

$$= G[B] - \left( \sum_{k=0}^{m-1} (P_{A|B} P_{B_j|A})^k (\text{Id}_{m_2} - P_{A|B} P_{B_j|A}) \right) \cdot G[B],$$

$$- \left( \sum_{k=0}^{m-1} (P_{B_j|A} P_{A|B})^k (P_{B_j|A} - P_{B_j|A} \text{Id}_{m_2}) + (P_{B_j|A} P_{A|B})^m P_{B_j|A} \right) \cdot G[A],$$

$$= ((P_{A|B} P_{B_j|A})^m)^t \cdot G[B] - ((P_{B_j|A} P_{A|B})^m P_{B_j|A})^t \cdot G[A],$$

Finally (2.15) and (4.7) then again (2.11), (2.12), (2.13) and (2.14) together imply

$$G^{(2m+2)}(f)$$

$$= G(f) - S_{1,\text{odd}}^{(m-1)}(f)^t \cdot G[A] - S_{2,\text{odd}}^{(m-1)}(f)^t \cdot G[B] - \mathbb{E}[f|B]^t \cdot G^{(2m+1)}[B]$$

$$= G(f) - \left( S_{1,\text{odd}}^{(m-1)}(f) - (P_{B_j|A} P_{A|B})^m P_{B_j|A} \cdot \mathbb{E}[f|B] \right)^t \cdot G[A],$$

$$- \left( S_{2,\text{odd}}^{(m-1)}(f) + (P_{A|B} P_{B_j|A})^m \cdot \mathbb{E}[f|B] \right)^t \cdot G[B],$$

$$= G(f) - S_{1,\text{even}}^{(m)}(f)^t \cdot G[A] - S_{2,\text{even}}^{(m)}(f)^t \cdot G[B],$$

and (2.15) is valid for $m + 1$. If $1 \leq i \leq m_1$ then $\mathbb{E}[1_{A_i}|B]$ is the $i$-th column of $P_{A_i|B}$ and $\mathbb{E}[1_{A_i}|A]$ is the $i$-th unit vector of $\mathbb{R}^{m_1}$ thus (2.15) for $m + 1$ and $f = 1_B$, in turn entails

$$G^{(2m+2)}[A]$$

$$= G[A] - \left( \sum_{k=0}^{m} (P_{B_j|A} P_{A|B})^k (\text{Id}_{m_1} - P_{B_j|A} P_{A|B}) \right) \cdot G[A],$$

$$- \left( \sum_{k=0}^{m-1} (P_{A|B} P_{B_j|A})^k (P_{A|B} - P_{A|B} \text{Id}_{m_1}) + (P_{A|B} P_{B_j|A})^m P_{A|B} \right) \cdot G[B],$$

$$= ((P_{B_j|A} P_{A|B})^m)^t \cdot G[A] - ((P_{A|B} P_{B_j|A})^m P_{A|B})^t \cdot G[B],$$

and also, thanks to (2.16) and (4.7),

$$G^{(2m+3)}(f)$$

$$= G(f) - \left( S_{1,\text{odd}}^{(m)}(f) - (P_{B_j|A} P_{A|B})^{m+1} \cdot \mathbb{E}[f|A] \right)^t \cdot G[A]$$

$$- \left( S_{2,\text{odd}}^{(m-1)}(f) + (P_{A|B} P_{B_j|A})^m \cdot \mathbb{E}[f|B] \right)^t \cdot G[B] - \mathbb{E}[f|A]^t \cdot G^{(2m+2)}[A]$$

$$= G(f) - S_{1,\text{odd}}^{(m)}(f)^t \cdot G[A] - S_{2,\text{odd}}^{(m)}(f)^t \cdot G[B],$$

which is (2.16) for $m + 1$.  

36
4.4 Proof of Proposition 11

Step 1. For \( m \geq 1 \) let \( 0_{m,m} \) be the \( m \times m \) null matrix. Also recall the vectors \( P(A) = (P(A_1), \ldots, P(A_{m_1})) \) and \( P(B) = (P(B_1), \ldots, P(B_{m_2})) \).

**Lemma 5.** Assume (ER). For \( l = 1, 2 \) there exists an invertible \( m_1 \times m_1 \) matrix \( U_l \) and an upper triangular \((m_1 - 1) \times (m_1 - 1)\) matrix \( T_l \) such that

\[
P_{B|A}P_{A|B} = U_1 \begin{pmatrix} 1 & 0_{1,m_1-1} \\ 0_{m_1-1,1} & T_1 \end{pmatrix} U_1^{-1}, \quad \lim_{k \to +\infty} T_1^k = 0_{m_1-1,m_1-1},
\]

\[
P_{A|B}P_{B|A} = U_2 \begin{pmatrix} 1 & 0_{1,m_1-1} \\ 0_{m_2-1,1} & T_2 \end{pmatrix} U_2^{-1}, \quad \lim_{k \to +\infty} T_2^k = 0_{m_2-1,m_2-1}.
\]

**Proof.** Since \( A \) is a partition, for \( 1 \leq i \leq m_2 \) the sum of the \( m_1 \) terms of row \( i \) of \( P_{A|B} \) is \( \sum_{j=1}^{m_1} P(A_j | B_i) = 1 \) hence \( P_{A|B} \) is stochastic. Likewise \( P_{B|A} \) is stochastic and, by stability, so are \( P_{A|B}P_{B|A} \) and \( P_{A|B}P_{A|B} \). Let the column of \( 1 \)’s associated to their eigenvalue \( 1 \) be in first position in their respective matrix \( U_1, U_2 \) of eigenvectors. The announced decomposition is always true with some upper triangular matrices \( T_l \) having Jordan decomposition \( T_l = D_l + N_l \) where \( D_l = Q_l \Delta_l Q_l^{-1}, \Delta_l \) is a diagonal \((m_1 - 1) \times (m_1 - 1)\) matrix, \( Q_l \) is an invertible \((m_1 - 1) \times (m_1 - 1)\) matrix and \( N_l \) is a nilpotent \((m_1 - 1) \times (m_1 - 1)\) matrix of order \( m_1 \geq 1 \) that commute with \( D_l \). Next observe that

\[
(P(A) \cdot P_{B|A}P_{A|B})_k = \sum_{i=1}^{m_1} P(A_i)(P_{B|A}P_{A|B})_{i,k}
\]

\[
= \sum_{i=1}^{m_1} P(A_i) \sum_{j=1}^{m_2} (P_{B|A})_{i,j}(P_{A|B})_{j,k}
\]

\[
= \sum_{j=1}^{m_2} \sum_{i=1}^{m_1} P(A_i)P(B_j | A_i)P(A_k | B_j) = P(A_k),
\]

which proves that \( P_{B|A}P_{A|B} \) has invariant probability \( P(A) \). Similarly, \( P(B) \) is invariant for \( P_{A|B}P_{B|A} \), and the first line of \( U_1^{-1} \) and \( U_2^{-1} \) is \( P[A] \) and \( P[B] \) respectively. Under (ER) these matrices are ergodic, which ensures that the eigenvalues of \( \Delta_l \) have moduli strictly less than the dominant \( 1 \) since it is the case of eigenvalues of \( T_l \) hence \( D_l \). It follows that

\[
\lim_{k \to +\infty} \Delta_l^k = 0_{m_l-1,m_l-1}, \quad l = 1, 2.
\]

Furthermore, since \( N_l \) and \( D_l \) commute it holds

\[
T_l^k = \sum_{j=0}^{m_l-1} \binom{k}{j} N_l^j D_l^{k-j}, \quad l = 1, 2, \quad k \geq n_l.
\]

We conclude that \( \lim_{k \to +\infty} T_l^k = 0_{m_l-1,m_l-1} \). \( \square \)

**Step 2.** Let \( V_1(f) = (\mathbb{E}[f|A] - P_{B|A} \cdot \mathbb{E}[f|B]) \) and \( V_2(f) = (\mathbb{E}[f|B] - P_{A|B} \cdot \mathbb{E}[f|A]) \).
Lemma 6. Under (ER) we have

$$\lim_{k \to +\infty} (P_{B|A}P_{A|B})^k \cdot V_1(f) = 0_{m_1,1}, \quad \lim_{k \to +\infty} (P_{A|B}P_{B|A})^k \cdot V_2(f) = 0_{m_2,1}.$$

Proof. By Lemma 5 we have

$$\lim_{k \to +\infty} (P_{B|A}P_{A|B})^k = \left( \begin{array}{c} P(A) \\ \vdots \\ P(A) \end{array} \right), \quad \lim_{k \to +\infty} (P_{A|B}P_{B|A})^k = \left( \begin{array}{c} P(B) \\ \vdots \\ P(B) \end{array} \right). \quad (4.8)$$

The scalar product of $P(A)$ by $V_1(f)$ is null since $P(A) \cdot \mathbb{E}[f|A] = P(f)$ and

$$P(A) \cdot P_{B|A}\mathbb{E}[f|B]) = \sum_{j=1}^{m_1} P(A_j) \sum_{k=1}^{m_2} P(B_k | A_j)\mathbb{E}(f|B_k)$$

$$= \sum_{j=1}^{m_1} \sum_{k=1}^{m_2} P(A_j \cap B_k)\mathbb{E}[f|B_k] = P(f).$$

Likewise we get $P(B) \cdot V_2(f) = 0$. \quad \square

The following convergences hold for any matrix norm. By Lemma 5 we have

$$\sum_{k=0}^{N} (P_{B|A}P_{A|B})^k = U_1 \begin{pmatrix} N+1 & 0_{m_1,1} \\ 0_{m_1,1} & \sum_{k=0}^{N} T_1^k \end{pmatrix} U_1^{-1},$$

$$\sum_{k=0}^{N} (P_{A|B}P_{B|A})^k = U_2 \begin{pmatrix} N+1 & 0_{m_2,1} \\ 0_{m_2,1} & \sum_{k=0}^{N} T_2^k \end{pmatrix} U_2^{-1}.$$

Now, the matrices $\text{Id}_{m_1-1} - T_1$ and $\text{Id}_{m_2-1} - T_2$ are nonsingular since 1 is a dominant eigenvalue of $P_{B|A}P_{A|B}$ and $P_{A|B}P_{B|A}$. Recalling (2.11) and (2.12), by Lemma 5 and 6 it follows that

$$S_{1,\text{even}}^{(N)}(f) = U_1 \begin{pmatrix} 0 \\ 0_{m_1-1,1} \text{Id}_{m_1-1} - T_1^{-1}(\text{Id}_{m_1-1} - T_1^{N+1}) \end{pmatrix} U_1^{-1} \cdot V_1(f),$$

$$S_{2,\text{odd}}^{(N)}(f) = U_2 \begin{pmatrix} 0 \\ 0_{m_2-1,1} \text{Id}_{m_2-1} - T_2^{-1}(\text{Id}_{m_2-1} - T_2^{N+1}) \end{pmatrix} U_2^{-1} \cdot V_2(f),$$

which, by Lemma 5 converge respectively to

$$S_{1,\text{even}}(f) = U_1 \begin{pmatrix} 0 \\ 0_{m_1-1,1} \text{Id}_{m_1-1} - T_1^{-1} \end{pmatrix} U_1^{-1} \cdot V_1(f),$$

$$S_{2,\text{odd}}(f) = U_2 \begin{pmatrix} 0 \\ 0_{m_2-1,1} \text{Id}_{m_2-1} - T_2^{-1} \end{pmatrix} U_2^{-1} \cdot V_2(f).$$

Since we have already seen by using (4.8) and the notations of Proposition 11 that

$$\lim_{k \to +\infty} (P_{B|A}P_{A|B})^k \cdot \mathbb{E}[f|A] = P_1[f], \quad \lim_{k \to +\infty} (P_{A|B}P_{B|A})^k \cdot \mathbb{E}[f|B] = P_2[f],$$

38
we conclude by [2.13] and [2.14] that $S_{1, \text{odd}}^{(N)}(f)$, $S_{2, \text{even}}^{(N)}(f)$ converge to the vectors $S_{1, \text{odd}}(f) = S_{1, \text{even}}(f) + P_1[f]$, $S_{2, \text{even}}(f) = S_{1, \text{odd}}(f) + P_1[f]$ respectively.

**Step 3.** Given the spectral radius $\rho(T_i) < 1$ of $T_i$ let $\lambda_i = \rho(T_i) + \varepsilon < 1$, $t = 1, 2$ for any $\varepsilon > 0$. Then there exists a vector norm $\| \cdot \|_t$ on $\mathbb{C}^{m_t-1}$ such that its induced matrix norm $\| \cdot \|_t$ on matrices $(m_t-1) \times (m_t-1)$ satisfies $\|T_i\|_t \leq \lambda_t$. Introduce the vector norm $\|(x_1, \ldots, x_m)^t\|_t = |x_1| + \|(x_2, \ldots, x_m)^t\|_t$ on $\mathbb{C}^{m_t}$ and the induced operator norm $\|\| \cdot \|\|_t^2$ for $m_t \times m_t$ matrices. Then we have

$$\left\| \begin{pmatrix} 0 & 0_{1,m_t-1} \\ 0_{m_t-1,1} & T \end{pmatrix} \right\|_t' = \sup \left\{ x \in \mathbb{C}^{m_t} : 0 + \|T(x_2, \ldots, x_m)^t\|_t \right\} = \|T\|_t,$$

for any $m_t \times m_t$ matrix $T$. Let $K_t = \|\|(\text{Id}_{m_t-1} - T_i)^{-1}\|_t$, $\tilde{K}_t = \|U_t\|_t \|U_t^{-1}\|_t$ and $K'_t > 0$ be such that $\|\|\cdot\|\|_t' \leq K'_t \|\|\cdot\|\|_t$. By using Lemmas 3 and 4 we get

$$\left\| S_{1, \text{even}}^{(N)}(f) - S_{1, \text{even}}(f) \right\|_t' \leq \tilde{K}_t \|\|(\text{Id}_{m_t-1} - T_i)^{-1}\|_t \|\|V_i(f)\|\|_t' \leq \tilde{K}_t \lambda_i K_t \|\|V_i(f)\|\|_\infty \leq c_t \lambda_i^{N+1},$$

where $c_t = \tilde{K}_t K_t$ $\lambda_i$. Similar constants show up for $\left\| S_{1, \text{odd}}^{(N)}(f) - S_{1, \text{odd}}(f) \right\|_t'$.

The final constants $c_1$ and $c_2$ depend on $\lambda_1, \lambda_2, \varepsilon$, both matrices (ER) but also the two implicit constants relating the norms $\|\| \cdot \|\|_{m_1}, \|\| \cdot \|\|_{m_2}$ of Proposition 1 to the equivalent norms $\|\| \cdot \|\|_{t_1}', \|\| \cdot \|\|_{t_2}'$.

### 4.5 Proof of Theorem 2.2

Write $Z_1 = \max_{1 \leq j \leq m_1} \|G(A_j)\|$ and $Z_2 = \max_{1 \leq j \leq m_2} \|G(B_j)\|$. According to Proposition 1 the random variables appearing on the right hand side of the following formulae, for $* \in \{\text{even}, \text{odd}\}$,

$$\sup_{f \in \mathcal{F}} \left| (S_{1, \ast}^{(N)}(f) - S_{1, \ast}(f))^t \cdot G[A] \right| \leq c_1 \sup_{f \in \mathcal{F}} \left\| S_{1, \ast}^{(N)}(f) - S_{1, \ast}(f) \right\|_{m_1} Z_1,$$

$$\sup_{f \in \mathcal{F}} \left| (S_{2, \ast}^{(N)}(f) - S_{2, \ast}(f))^t \cdot G[B] \right| \leq c_2 \sup_{f \in \mathcal{F}} \left\| S_{2, \ast}^{(N)}(f) - S_{2, \ast}(f) \right\|_{m_2} Z_2,$$

almost surely converge to 0 since $P(\|G\|_F < +\infty) = 1$. Hence the processes $G^{(2m)}$, $G^{(2m+1)}$ converge almost surely in $\ell^\infty(\mathcal{F})$ to $G^{(\infty)}_{\text{even}}, G^{(\infty)}_{\text{odd}}$ defined by

$$G^{(\infty)}_{\text{even}}(f) = G(f) - S_{1, \text{even}}(f)^t \cdot G[A] - S_{2, \text{even}}(f)^t \cdot G[B],$$

$$G^{(\infty)}_{\text{odd}}(f) = G(f) - S_{1, \text{odd}}(f)^t \cdot G[A] - S_{2, \text{odd}}(f)^t \cdot G[B],$$

$$= G^{(\infty)}(f) - P_1[f]^t \cdot G[A],$$

where $G^{(\infty)}(f) = G(f) - P_2[f]^t \cdot G[B]$. 

39
Let $\Phi$ denote the standard Gaussian distribution function, whence an upper bound for the Lévy-Prokhorov distance
\[
d_L P(G^{(N)}, G^{(\infty)}) \leq \max \left( \mathbb{P} \left( \left\| G^{(N)} - G^{(\infty)} \right\|_F > \varepsilon_N \right), \varepsilon_N \right) \leq c_0 q_N \max(\lambda_1, \lambda_2)^{N/2}.
\]
Let $\Phi$ denote the standard Gaussian distribution function, $c_5 = m_1 + m_2$ and $c_4^2 = \max_{D \in A \cup B} \{ P(D)(1 - P(D)) \}$. The union bound
\[
\mathbb{P}(Z > \lambda) \leq c_5 \left( 1 - \Phi \left( \frac{\lambda}{c_4} \right) \right) \leq \frac{c_5 c_4 \lambda}{\sqrt{2\pi}} \exp \left( - \frac{\lambda^2}{2c_4^2} \right),
\]
shows that $q_N = c_6 c_4 \sqrt{N \log(1/c_0 \max(\lambda_1, \lambda_2))}$ for some $c_6 > 0$.

**Appendix**

.1 Elementary example

The Raking-Ratio algorithm changes the weights of cells of a contingency table in such a way that given margins are respected, just as if the sample should have respected the expected values of known probabilities. Let us illustrate the method from the following basic two-way contingency table.

| $\mathbb{P}_n(1_{A_1} \cap 1_{A_2})$ | $A_1^{(2)}$ | $A_2^{(2)}$ | $A_3^{(2)}$ | Total | Expected total |
|----------------------------------|------------|------------|------------|------|----------------|
| $A_1^{(1)}$                      | 0.2        | 0.25       | 0.1        | 0.55 | 0.52           |
| $A_2^{(1)}$                      | 0.1        | 0.2        | 0.15       | 0.45 | 0.48           |
| Total                            | 0.3        | 0.45       | 0.25       | 1    |                |
| Expected total                   | 0.31       | 0.4        | 0.29       | N = 0 |                |
The margins of this sample differ from the known margins, here called expected total. Firstly the weights of lines are corrected, hence each cell is multiplied by the ratio of the expected total and the actual one, this is step $N = 1$.

\[
\begin{array}{cccccc}
 & A_1^{(2)} & A_2^{(2)} & A_3^{(2)} & \text{Total} & \text{Expected total} \\
A_1^{(1)} & 0.189 & 0.236 & 0.095 & 0.52 & 0.52 \\
A_2^{(1)} & 0.11 & 0.21 & 0.16 & 0.48 & 0.48 \\
\text{Total} & 0.299 & 0.446 & 0.255 & 1 & N = 1 \\
\end{array}
\]

The totals for each column are similarly corrected at step $N = 2$. Typically the margins of the lines no longer match the expected frequencies. Here they move in the right direction. Some estimators based on $P_{n}^{(2)}$ may be improved.

\[
\begin{array}{cccccc}
 & A_1^{(2)} & A_2^{(2)} & A_3^{(2)} & \text{Total} & \text{Expected total} \\
A_1^{(1)} & 0.196 & 0.212 & 0.108 & 0.516 & 0.52 \\
A_2^{(1)} & 0.114 & 0.188 & 0.182 & 0.484 & 0.48 \\
\text{Total} & 0.31 & 0.4 & 0.29 & 1 & N = 2 \\
\end{array}
\]

The last two operations are repeated until stabilization. The algorithm converges to the Kullback projection of the initial joint law. The rate depends only on the initial table compared to the desired marginals. It takes only 7 iterations in our case to match the expected margins.

\[
\begin{array}{cccccc}
 & A_1^{(2)} & A_2^{(2)} & A_3^{(2)} & \text{Total} & \text{Expected total} \\
A_1^{(1)} & 0.199 & 0.212 & 0.109 & 0.52 & 0.52 \\
A_2^{(1)} & 0.111 & 0.188 & 0.181 & 0.48 & 0.48 \\
\text{Total} & 0.31 & 0.4 & 0.29 & 1 & N = 7 \\
\end{array}
\]

The final raked frequencies are slightly moved away the initial ones, however this has to be compared with the natural sampling oscillation order $1/\sqrt{n}$ – insidiously $n$ was not mentioned. For small samples such changes are likely to occur that may improve a large class of estimators, and worsen others. Our theoretical results showed that the improvement is uniform over a large class as $n \to +\infty$ and $N$ is fixed.

### 2 Counterexample of Remark J

Let assume that $P$ satisfies the following probability values

| $P(A_i \cap B_j)$ | $A_1$ | $A_2$ | $A_3$ | $P(B_j)$ |
|-------------------|------|------|------|--------|
| $B_1$             | 0.2  | 0.25 | 0.1  | 0.55   |
| $B_2$             | 0.25 | 0.1  | 0.1  | 0.45   |
| $P(A_i)$          | 0.45 | 0.35 | 0.2  |        |
and that $f$ has the following conditional expectations

| $\mathbb{E}(f|A_1 \cap B_j)$ | $A_1$ | $A_2$ | $A_3$ | $\mathbb{E}(^{(2)}(f) \simeq$ |
|---------------------------|------|------|------|-------------------|
| $B_1$                     | 0.75 | -0.5 | 0.5  | 0.136             |
| $B_2$                     | 0.5  | 0.25 | 0.5  | 0.444             |
| $\mathbb{E}(^{(1)}(f) \simeq$ | 0.611 | -0.286 | 0.5  |

By supposing also that $\mathbb{V}(f|A_i \cap B_j) = 0.5$ for all $i = 1, 2, 3$ and $j = 1, 2$ we can compute the theoretical limiting variances from Proposition 7. We get $\mathbb{V}(\mathbb{G}^{(0)}(f)) \simeq 0.734$; $\mathbb{V}(\mathbb{G}^{(1)}(f)) \simeq 0.563$; $\mathbb{V}(\mathbb{G}^{(2)}(f)) \simeq 0.569$; $\mathbb{V}(\mathbb{G}^{(3)}(f)) \simeq 0.402$. The fact that $\mathbb{V}(\mathbb{G}^{(2)}(f)) > \mathbb{V}(\mathbb{G}^{(1)}(f))$ shows that the variance doesn’t decrease necessarily at each step. As predicted by Propositions 8 and 9 we have $\mathbb{V}(\mathbb{G}^{(N)}(f) < \mathbb{V}(\mathbb{G}^{(0)}(f))$ for $N = 1, 2, 3$ and $\mathbb{V}(\mathbb{G}^{(3)}(f)) < \mathbb{V}(\mathbb{G}^{(1)}(f))$.

.3 Raked empirical means over a class

**General framework.** Many specific settings in statistics may be modeled through $\mathcal{F}$. Typically $\mathcal{X}$ is of very large or infinite dimension and each $f(X)$ is one variable with mean $P(f)$ in the population. To control correlations between such variables one needs to extend $\mathcal{F}$ into $\mathcal{F}_\mathcal{X} = \{fg : f, g \in \mathcal{F}\}$ and consider the covariance process $\alpha^{(N)}_n(\mathcal{F}_\mathcal{X})$. Random vectors $(Y_1, ..., Y_k) = (f_1(X), ..., f_k(X))$ can in turn be combined into real valued random variables $g_\theta(X) = \varphi_\theta(Y_1, ..., Y_k)$ through parameters $\theta$ and functions $g_\theta$ that should be included in $\mathcal{F}$ and so on. Consider for instance $g_\theta(X) = \theta_1 Y_1 + ... + \theta_k Y_k + \varepsilon_\sigma(X)$ with a collection of possible residual functions $\varepsilon_\sigma$ turning part of the randomness of $X$ into a noise with variance $\sigma^2$. The (VC) or (BR) entropy of $\mathcal{F}$ rules the variety and complexity of models or statistics one can simultaneously deal with. We refer to Pollard [20], Shorack and Wellner [21] and Wellner [29] for classical statistical models where an empirical process indexed by functions is easily identified.

**Direct applications.** Since the limiting process $\mathbb{G}^{(N)}$ of $\alpha^{(N)}_n$ has less variance than $\mathbb{G}^{(0)}$, Theorem 1 can be applied to revisit the limiting behavior of classical estimators or tests by using $\mathbb{P}_n^{(N)}$ instead of $\mathbb{P}_n$ and prove that the induced asymptotic variances or risk decrease. For instance, in the case of goodness of fit tests, the threshold decreases at any given test level while the power increases against any alternative distribution $Q$ that do not satisfy the margin conditions. As a matter of fact, enforcing $\mathbb{P}_n^{(N)}$ to look like $P$ instead of the true $Q$ over all $\mathcal{A}^{(N)}$ makes $\mathbb{P}_n^{(N)}$ go very far from $P$ on sets where $Q$ was already far from $P$.

**Example: two raked distribution functions.** Let $(X, Y)$ be a real centered Gaussian vector with covariance matrix $\left( \begin{smallmatrix} 3 & -1 \\ -1 & 1 \end{smallmatrix} \right)$. We consider the raked joint estimation of the two distribution functions $F_X, F_Y$. An auxiliary information provides their values at points $-2$ to $2$, every $0.5$. The class $\mathcal{F}$ we need contains for all $t \in \mathbb{R}$ the functions $f_t^X(x, y) = 1_{[-\infty,t]}(x), f_t^Y(x, y) = 1_{[-\infty,t]}(y)$ thus (VC) holds. For $Z = X, Y$ let $F_{Z,n}(t) = \sum_{Z_i \leq t} \mathbb{P}_n^{(N)}(\{Z_i\})$ be the $N$-th raked empirical distribution function and write $Z_{(1)} \leq \cdots \leq Z_{(n)}$ the order statistics. To exploit at best the information we use $N = 2m, F_{Z,n}^{(2m-1)}$ and $F_{Z,n}^{(2m)}$. Consider

42
\[d_{Z,n}^{(N)} = \sum_{i=1}^{n-1} |Z_{(i+1)} - Z_{(i)}| F_{Z,n}^{(N)}(Z_{(i+1)}) - F_{Z}(Z_{(i+1)})|\] which approximates on \([Z(1), Z(n)]\) the \(L^1\)-distance between \(F_{Z,n}^{(N)}\) and \(F_{Z}\). Denote \(\#_{Z,n}^{(N)}\) the random proportion of sample points where \(F_{Z,n}^{(N)}\) is closer to \(F_{Z}\) than \(F_{Z,n}^{(0)}\). The table below provides Monte-Carlo estimates of \(D_{Z,n}^{(N)} = \mathbb{E}(d_{Z,n}^{(N)})\) and \(\#_{Z,n}^{(N)} = \mathbb{E}(\#_{Z,n}^{(N)})\) from 1000 simulations based on samples of size \(n = 200\):

| \(Z\) | \(D_{Z,n}^{(0)}\) | \(D_{Z,n}^{(10)}\) | \(D_{Z,n}^{(\infty)}\) | \(\#_{Z,n}^{(10)}\) | \(\#_{Z,n}^{(\infty)}\) |
|---|---|---|---|---|---|
| \(X\) | 0.084 | 0.098 | 0.065 | 0.752 | 0.724 |
| \(Y\) | 0.085 | 0.043 | 0.053 | 0.731 | 0.081 |

This shows some improvement, especially for \(N = 10\). For \(n\) rather small it seems not always relevant to wait for the stabilization of the algorithm – here denoted \(N = \infty\). Our theoretical results provide guarantees only for \(N \leq N_0\), \(N_0\) fixed and \(n \geq n_0\) for \(n_0 > 0\). We also observed on graphical representations that the error at a few short intervals where \(F_{Z,n}^{(0)}\) leaves \(F_{Z}\) to cross \(F_{Z}\) at the known points tends to accentuate the error at a few short intervals where \(F_{Z,n}^{(0)}\) is far from \(F_{Z}\). This is less the case as the auxiliary information partition is refined or the sample size increases.

**Example: raked covariance matrices.** Given \(d \in \mathbb{N}^\ast\) and \(f_1, \ldots, f_d\) let \(\mathbb{V}(Y)\) denote the covariance matrix of the random vector \(Y = (f_1(X), \ldots, f_d(X))\) which we assume to be centered for simplicity. Instead of the empirical covariance \(\mathbb{V}_{n}^{(0)}(Y) = n^{-1} \sum_{i=1}^{n} Y_i Y_i'\), consider its raked version

\[
\mathbb{V}_{n}^{(N)}(Y) = \left(\mathbb{P}_{n}^{(N)}(f_i, f_j)\right)_{i,j}.
\]

Let \(\|\cdot\|\) denote the Frobenius norm and define

\[
\varphi_{Y}(\alpha_{n}^{(N)}) = \sqrt{n} \left\| \mathbb{V}_{n}^{(N)}(Y) - \mathbb{V}(Y) \right\|.
\]

In other words,

\[
\varphi_{Y}^{2}(\alpha_{n}^{(N)}) = \sum_{i=1}^{d} \sum_{j=1}^{d} \left(\alpha_{n}^{(N)}(f_i, f_j)\right)^2, \quad \varphi_{Y}^{2}(\mathbb{G}^{(N)}) = \sum_{i=1}^{d} \sum_{j=1}^{d} \left(\mathbb{G}^{(N)}(f_i, f_j)\right)^2.
\]

In the context of Proposition 6 observe that \(\varphi_{Y}\) is \((\|\cdot\|_F, \|\cdot\|)\)-Lipschitz with parameter \(C_1 = d\). Clearly \(\varphi_{Y}(\mathbb{G}^{(N)})\) has a bounded density since \(\varphi_{Y}^{2}(\mathbb{G}^{(N)})\) is a quadratic form with Gaussian components and has a modified \(\chi^2\) distribution. Choosing a finite collection of such \(\varphi_{Y}\) ensures that \(C_2 < +\infty\). More generally by letting \((f_1, \ldots, f_d)\) vary among a small entropy infinite subset \(\mathcal{L}_d\) of \(\mathcal{F}\) and imposing some regularity or localization constraints to the \(f_i\) one may have \(C_2 < +\infty\) while \(\{f_i, f_j : f_i, f_j \in \mathcal{F}\}\) satisfies (BR). The largest \(C_2\) still works for \(\mathcal{L} = \bigcup_{d \leq d_0} \mathcal{L}_d\). Therefore Proposition 6 guarantees that

\[
\max_{0 \leq N \leq N_0} \sup_{d \leq d_0} \left(\mathbb{P}_{x > 0} \left(\varphi_{Y}(\alpha_{n}^{(N)}) \leq x\right) - \mathbb{P}_{x > 0} \left(\varphi_{Y}(\mathbb{G}^{(N)}) \leq x\right)\right) \leq d_1 C_1 C_2 v_n,
\]

43
where it holds, for all $N \leq N_0$, $d_0 \leq d_1$, $(f_1, \ldots, f_d) \in L_d$ and $x > 0$,

$$
P \left( \varphi_Y(G^{(N)}) \leq x \right) \leq P \left( \varphi_Y(G^{(0)}) \leq x \right),
$$

by the variance reduction property of Proposition 3. Hence we asymptotically have $P(\varphi_Y(\alpha_n^{(N)}) \leq x) < P(\varphi_Y(\alpha_n^{(0)}) \leq x) - \varepsilon$ uniformly among $Y$ such that $P (\varphi_Y(G^{(N)}) \leq x) < P (\varphi_Y(G^{(0)}) \leq x) - 2\varepsilon$, for any fixed $\varepsilon > 0$.
