REAL-VALUED VALUATIONS ON SOBOLEV SPACES

DAN MA

ABSTRACT. Continuous, SL(n) and translation invariant real-valued valuations on Sobolev spaces are classified.

1. Introduction

A function \( z \) defined on a lattice \( (L, \lor, \land) \) and taking values in an abelian semigroup is called a valuation if

\[
(1) \quad z(f \lor g) + z(f \land g) = z(f) + z(g)
\]

for all \( f, g \in L \). A function \( z \) defined on some subset \( M \) of \( L \) is called a valuation on \( M \) if \( (1) \) holds whenever \( f, g, f \lor g, f \land g \in M \). Valuations were a key part of Dehn’s solution of Hilbert’s Third Problem in 1901. They are closely related to dissections and lie at the very heart of geometry. Here, valuations were considered on the space of convex bodies (i.e. compact convex sets) in \( \mathbb{R}^n \), denoted by \( K^n \). Perhaps the most famous result is Hadwiger’s characterization theorem on this space which classifies all continuous and rigid motion invariant real-valued valuations. Important later contributions can be found in [11, 14, 27, 28]. As for recent results, we refer to [1, 2, 5–8, 10, 12, 13, 17, 19–21, 25, 26, 30–34, 38]. For later reference, we state here a centro-affine version of Hadwiger’s characterization theorem on the space of convex polytopes containing the origin in their interiors, which is denoted by \( P^n_0 \).

Theorem 1 ( [9]). A map \( Z : P^n_0 \to \mathbb{R} \) is an upper semicontinuous and SL(n) invariant valuation if and only if there exist constants \( c_0, c_1, c_2 \in \mathbb{R} \) such that

\[
Z(P) = c_0 + c_1 |P| + c_2 |P^*|
\]

for all \( P \in P^n_0 \), where \( |P| \) is the volume of \( P \) and

\[
P^* = \{ x \in \mathbb{R}^n : \langle x, y \rangle \leq 1 \text{ for all } y \in P \}
\]

is the polar of \( P \).

Date: August 24, 2015.

2010 Mathematics Subject Classification. 46B20, 46E35, 52A21, 52B45.
Valuations are also considered on spaces of real-valued functions. Here, we take the pointwise maximum and minimum as the join and meet, respectively. Two important functions associated with every convex body $K$ in $\mathbb{R}^n$ are the indicator function $1_K$ and the support function $h(K, \cdot)$, where $h(K, u) = \max \{ \langle u, x \rangle : x \in K \}$ and $\langle u, x \rangle$ is the standard inner product of $u, x \in \mathbb{R}^n$. As each of them is in one-to-one correspondence with $K$, valuations on these function spaces are often considered to be valuations on convex bodies.

Valuations on other classical function spaces have been characterized since 2010. Tsang [35] characterized real-valued valuations on $L^p$-spaces.

**Theorem 2** ([35]). A functional $z : L^p(\mathbb{R}^n) \to \mathbb{R}$ is a continuous translation invariant valuation if and only if there exists a continuous function on $\mathbb{R}$ with the property that there exists $c \geq 0$ such that $|h(x)| \leq c |x|^p$ for all $x \in \mathbb{R}$ and

$$z(f) = \int_{\mathbb{R}^n} h \circ f$$

for every $f \in L^p(\mathbb{R}^n)$.

Kone [15] generalized this characterization to Orlicz spaces. As for valuations on Sobolev spaces, Ludwig characterized the Fisher information matrix and the optimal Sobolev body. Throughout this paper, the Sobolev space on $\mathbb{R}^n$ with indices $k$ and $p$ is denoted by $W^{k,p}(\mathbb{R}^n)$ (see Section 2 for precise definitions) and the additive group of real symmetric $n \times n$ matrices is denoted by $\langle \mathbb{M}^n, + \rangle$. An operator $z : W^{1,2}(\mathbb{R}^n) \to \langle \mathbb{M}^n, + \rangle$ is called $GL(n)$ contravariant if for some $p \in \mathbb{R}$,

$$z \left( f \circ \phi^{-1} \right) = |\det \phi|^p \phi^{-t} z(f) \phi^{-1}$$

for all $f \in W^{1,2}(\mathbb{R}^n)$ and $\phi \in GL(n)$, where $\det \phi$ is the determinant of $\phi$ and $\phi^{-t}$ denotes the inverse of the transpose of $\phi$. An operator $z : W^{1,2}(\mathbb{R}^n) \to \langle \mathbb{M}^n, + \rangle$ is called affinely contravariant if it is $GL(n)$ contravariant, translation invariant, and homogeneous (see Section 2 for precise definitions).

**Theorem 3** ([22]). An operator $z : W^{1,2}(\mathbb{R}^n) \to \langle \mathbb{M}^n, + \rangle$, where $n \geq 3$, is a continuous and affinely contravariant valuation if and only if there is a constant $c \in \mathbb{R}$ such that

$$z(f) = c \int_{\mathbb{R}^n} \nabla f \otimes \nabla f$$

for every $f \in W^{1,2}(\mathbb{R}^n)$. 

Other recent and interesting characterizations can be found in [3, 4, 24, 29, 36, 37].

In this paper, we classify real-valued valuations on $W^{1,p}(\mathbb{R}^n)$. The result regarding homogeneous valuations is stated first. Let $1 \leq p < n$ throughout this paper. Furthermore, we say that a valuation is trivial if it is identically zero.

**Theorem 4.** A functional $z : W^{1,p}(\mathbb{R}^n) \to \mathbb{R}$ is a non-trivial continuous, SL($n$) and translation invariant valuation that is homogeneous of degree $q$ if and only if $p \leq q \leq \frac{np}{n-p}$ and there exists a constant $c \in \mathbb{R}$ such that

$$z(f) = c \|f\|_q^q$$

for every $f \in W^{1,p}(\mathbb{R}^n)$.

It is natural to consider the same characterization without the assumption of homogeneity. It turns out to be more complicated and costs additional assumptions. We first fix the following notation. Let $C^k(\mathbb{R}^n)$ denote the space of functions on $\mathbb{R}^n$ that have $k$ times continuous partial derivatives for a positive integer $k$; let $BV_{loc}(\mathbb{R})$ denote the space of functions on $\mathbb{R}$ that are of locally bounded variation. We denote by $G_p$ the class of functions $g$ that belong to $BV_{loc}(\mathbb{R})$ and satisfy

$$g(x) \sim \begin{cases} O(x^p), & \text{as } x \to 0; \\ O(x^{\frac{n p}{n-p}}), & \text{as } x \to \infty. \end{cases}$$

and by $B_p$ the class of functions $g$ that belong to $C^n(\mathbb{R})$ with $g^{(n)} \in BV_{loc}(\mathbb{R})$ and $x^k g^{(k)}(x)$ satisfying (3) for each integer $1 \leq k \leq n$. Let $P^{1,p}(\mathbb{R}^n)$ be the set of functions $\ell_P$ with $P \in \mathcal{P}^n_0$ that enclose pyramids of height 1 on $P$ (see Section 2 for the precise definition).

**Theorem 5.** A functional $z : W^{1,p}(\mathbb{R}^n) \to \mathbb{R}$ is a continuous, SL($n$) and translation invariant valuation with $z(0) = 0$ and $s \mapsto z(sf)$ in $B_p$ for $s \in \mathbb{R}$ and $f \in P^{1,p}(\mathbb{R}^n)$ if and only if there exists a continuous function $h \in G_p$ such that

$$z(f) = \int_{\mathbb{R}^n} h \circ f,$$

for every $f \in W^{1,p}(\mathbb{R}^n)$.

The proofs of Theorem 4 and 5 can be found in Sections 3 and 4, respectively.
2. Preliminaries

For $p \geq 1$ and a measurable function $f : \mathbb{R}^n \rightarrow \mathbb{R}$, let
\[
\|f\|_p = \left( \int_{\mathbb{R}^n} |f(x)|^p \, dx \right)^{1/p}.
\]
Define $L^p(\mathbb{R}^n)$ to be the class of measurable functions with $\|f\|_p < \infty$ and $L^p_{loc}(\mathbb{R}^n)$ to be the class of measurable functions with $\|f\mathbb{1}_K\|_p < \infty$ for every compact $K \subset \mathbb{R}^n$.

A measurable function $\nabla f : \mathbb{R}^n \rightarrow \mathbb{R}^n$ is said to be the weak gradient of $f \in L^p(\mathbb{R}^n)$ if
\[
\int_{\mathbb{R}^n} \nu(x) \cdot \nabla f(x) \, dx = -\int_{\mathbb{R}^n} f(x) \nabla \cdot \nu(x) \, dx
\]
for every compactly supported smooth vector field $\nu : \mathbb{R}^n \rightarrow \mathbb{R}^n$, where $\nabla \cdot \nu = \frac{\partial \nu_1}{\partial x_1} + \cdots + \frac{\partial \nu_n}{\partial x_n}$. A function $f \in L^1(\mathbb{R}^n)$ is said to be of bounded variation on $\mathbb{R}^n$ if there exists a finite signed vector-valued Radon measure $\lambda$ on $\mathbb{R}^n$ such that
\[
\int_{\mathbb{R}^n} \nu(x) \cdot \nabla f(x) \, dx = \int_{\mathbb{R}^n} \nu(x) \cdot d\lambda(x)
\]
for every $\nu$ as mentioned before. A function $f \in L^1_{loc}(\mathbb{R}^n)$ is said to be of locally bounded variation on $\mathbb{R}^n$ if $f$ is of bounded variation on all open subset of $\mathbb{R}^n$.

The Sobolev space $W^{1,p}(\mathbb{R}^n)$ consists of all functions $f \in L^p(\mathbb{R}^n)$ whose weak gradient belongs to $L^p(\mathbb{R}^n)$ as well. For each $f \in W^{1,p}(\mathbb{R}^n)$, we define the Sobolev norm to be
\[
\|f\|_{W^{1,p}(\mathbb{R}^n)} = \left( \|f\|_p^p + \|
abla f\|_p^p \right)^{1/p},
\]
where $\|
abla f\|_p$ denotes the $L^p$ norm of $|\nabla f|$. Equipped with the Sobolev norm, the Sobolev space $W^{1,p}(\mathbb{R}^n)$ is a Banach space.

Theorem 6 ([18]). Let $\{f_j\}$ be a sequence in $W^{1,p}(\mathbb{R}^n)$ that converges to $f \in W^{1,p}(\mathbb{R}^n)$. Then, there exists a subsequence $\{f_{j_k}\}$ that converges to $f$ a.e. as $j \rightarrow \infty$.

Furthermore, for $1 \leq p < n$, $W^{1,p}(\mathbb{R}^n)$ is continuously embedded in $L^q(\mathbb{R}^n)$ for all $p \leq q \leq p^*$, where $p^* = \frac{np}{n-p}$ is the Sobolev conjugate of $p$, due to the Sobolev-Gagliardo-Nirenberg inequality stated as the following theorem.

Theorem 7 ([16]). Let $1 \leq p < n$. There exists a positive constant $C$, depending only on $p$ and $n$, such that
\[
\|f\|_{p^*} \leq C \|
abla f\|_p
\]
for all \( f \in W^{1,p}(\mathbb{R}^n) \).

Remark 8. By Theorem 7, the expression in (2) is well defined.

For \( f, g \in W^{1,p}(\mathbb{R}^n) \), we have \( f \lor g, f \land g \in W^{1,p}(\mathbb{R}^n) \) and for almost every \( x \in \mathbb{R}^n \),

\[
\nabla (f \lor g)(x) = \begin{cases} 
\nabla f(x), & \text{when } f(x) > g(x) \\
\nabla g(x), & \text{when } f(x) < g(x) \\
\n\nabla f(x) = \nabla g(x), & \text{when } f(x) = g(x)
\end{cases}
\]

and

\[
\nabla (f \land g)(x) = \begin{cases} 
\nabla f(x), & \text{when } f(x) < g(x) \\
\n\nabla g(x), & \text{when } f(x) > g(x) \\
\n\nabla f(x) = \nabla g(x), & \text{when } f(x) = g(x)
\end{cases}
\]

(see [18]). Hence \((W^{1,p}(\mathbb{R}^n), \lor, \land)\) is a lattice.

Let \( L^{1,p}(\mathbb{R}^n) \subset W^{1,p}(\mathbb{R}^n) \) be the space of piecewise affine functions on \( \mathbb{R}^n \). Here, a function \( \ell : \mathbb{R}^n \to \mathbb{R} \) is called piecewise affine, if it is continuous and there exists a finite number of \( n \)-dimensional simplices \( \triangle_1, \ldots, \triangle_m \subset \mathbb{R}^n \) with pairwise disjoint interiors such that the restriction of \( \ell \) to each \( \triangle_i \) is affine and \( \ell = 0 \) outside \( \triangle_1 \cup \cdots \cup \triangle_m \). The simplices \( \triangle_1, \ldots, \triangle_m \) are called a triangulation of the support of \( \ell \). Let \( V \) denote the set of vertices of this triangulation. We further have that \( V \) and the values \( \ell(v) \) for \( v \in V \) completely determine \( \ell \). Piecewise affine functions lie dense in \( W^{1,p}(\mathbb{R}^n) \) (see [16]).

For \( P \in \mathcal{P}_0^n \), define the piecewise affine function \( \ell_P \) by requiring that \( \ell_P(0) = 1 \), \( \ell_P(x) = 0 \) for \( x \notin P \), and \( \ell_P \) is affine on each simplex with apex at the origin and base among facets of \( P \). Define \( P^{1,p}(\mathbb{R}^n) \subset L^{1,p}(\mathbb{R}^n) \) as the set of all \( \ell_P \) for \( P \in \mathcal{P}_0^n \). For \( \phi \in \text{GL}(n) \), we have \( \ell_{\phi P} = \ell_P \circ \phi^{-1} \). We remark that multiples and translates of \( \ell_P \in P^{1,p}(\mathbb{R}^n) \) correspond to linear elements within the theory of finite elements.

For \( P \in \mathcal{P}_0^n \), let \( F_1, \ldots, F_m \) be the facets of \( P \). For each facet \( F_i \), let \( u_i \) be its unit outer normal vector and \( T_i \) the convex hull of \( F_i \) and the origin. For \( x \in T_i \), notice that

\[
\ell_P(x) = -\left\langle \frac{u_i}{h(P, u_i)}, x \right\rangle + 1
\]

and

\[
\nabla \ell_P(x) = -\frac{u_i}{h(P, u_i)}.
\]
It follows that
\[ \| \ell_P \|_p^p = \int_{\mathbb{R}^n} |\ell_P|^p \, dx \]
\[ = p \int_0^1 t^{p-1} |\{ \ell_P > t \}| \, dt \]
\[ = p |P| \int_0^1 t^{p-1} (1-t)^n \, dt \]
\[ = c_{p,n} |P|, \]
where \( c_{p,n} = \frac{\Gamma(p+1)\Gamma(n+1)}{\Gamma(n+p+1)} = \frac{(n+p)^{-1}}{n}, \) and
\[ \| \nabla \ell_P \|_p^p = \int_{\mathbb{R}^n} |\nabla \ell_P(x)|^p \, dx \]
\[ = \sum_{i=1}^m \int_{T_i} \left| \frac{u_i}{h(P,u_i)} \right|^p \, dx \]
\[ = \sum_{i=1}^m \frac{|T_i|}{h^p(P,u_i)} \]
\[ = \frac{1}{n} \sum_{i=1}^m |F_i| h^{1-p}(P,u_i) \]
\[ = \frac{1}{n} S_p(P), \]
where \( S_p(P) \) is the \( p \)-surface area of \( P \).

Let \( z : W^{1,p}(\mathbb{R}^n) \to \mathbb{R} \) be a functional. The functional is called continuous if for every sequence \( f_k \in W^{1,p}(\mathbb{R}^n) \) with \( f_k \to f \) as \( k \to \infty \) with respect to the Sobolev norm, we have \( |z(f_k) - z(f)| \to 0 \) as \( k \to \infty \). It is said to be translation invariant if \( z(f \circ \tau^{-1}) = z(f) \) for all \( f \in W^{1,p}(\mathbb{R}^n) \) and translations \( \tau \). Furthermore, we say it is homogeneous if for some \( q \in \mathbb{R} \), we have \( z(sf) = |s|^q z(f) \) for all \( f \in W^{1,p}(\mathbb{R}^n) \) and \( s \in \mathbb{R} \). Finally, we call the functional \( SL(n) \) invariant if \( z(f \circ \phi^{-1}) = z(f) \) for all \( f \in W^{1,p}(\mathbb{R}^n) \) and \( \phi \in SL(n) \). Denote the derivative of the map \( s \mapsto z(sf) \) by
\[ Dz_f(s) = \lim_{\varepsilon \to 0} \frac{z((s + \varepsilon)f) - z(sf)}{\varepsilon} \]
whenever it exists.

We provide a set of examples of valuations on \( W^{1,p}(\mathbb{R}^n) \) in the following theorem.
Theorem 9. Let \( h \in \mathcal{G}_p \) be a continuous function. Then, for every \( f \in W^{1,p}(\mathbb{R}^n) \), the functional

\[
z(f) = \int_{\mathbb{R}^n} h \circ f
\]

is a continuous, \( SL(n) \) and translation invariant valuation. Furthermore, \( z(0) = 0 \) and the map \( s \mapsto z(sf) \) belongs to \( \mathcal{B}_p \) for every \( s \in \mathbb{R} \) and \( f \in P^{1,p}(\mathbb{R}^n) \).

Proof. We can easily prove this theorem by verifying the following distinguishable properties of the functional.

1. Valuation. Let \( f, g \in W^{1,p}(\mathbb{R}^n) \) and \( E = \{ x \in \mathbb{R}^n : f(x) \geq g(x) \} \). Then

\[
z(f \vee g) + z(f \land g) = \int_{\mathbb{R}^n} h \circ (f \vee g) + \int_{\mathbb{R}^n} h \circ (f \land g)
\]

\[
= \int_E h \circ (f \vee g) + \int_{\mathbb{R}^n \setminus E} h \circ (f \vee g)
\]

\[
+ \int_E h \circ (f \land g) + \int_{\mathbb{R}^n \setminus E} h \circ (f \land g)
\]

\[
= \int_E h \circ f + \int_{\mathbb{R}^n \setminus E} h \circ g + \int_E h \circ g + \int_{\mathbb{R}^n \setminus E} h \circ f
\]

\[
= \int_{\mathbb{R}^n} h \circ f + \int_{\mathbb{R}^n} h \circ g
\]

\[
= z(f) + z(g).
\]

2. Continuity. Let \( f \in W^{1,p}(\mathbb{R}^n) \) and \( \{ f_i \} \) be a sequence in \( W^{1,p}(\mathbb{R}^n) \) that converges to \( f \). For every subsequence \( \{ z(f_{i_j}) \} \subset\{ z(f_i) \} \), we are going to show that there exists a subsequence \( \{ z(f_{i_{j_k}}) \} \) that converges to \( z(f) \). Let \( \{ f_{i_j} \} \) be a subsequence of \( \{ f_i \} \). Then, \( \{ f_{i_j} \} \) converges to \( f \) in \( W^{1,p}(\mathbb{R}^n) \). Thus, there exists a subsequence \( \{ f_{i_{j_k}} \} \subset \{ f_{i_j} \} \) with \( f_{i_{j_k}} \to f \) a.e. as \( k \to \infty \). Furthermore, since \( h \) is continuous, we obtain \( h \circ f_{i_{j_k}} \to h \circ f \) a.e. as \( k \to \infty \). Since \( h \) satisfies (3), there exist \( \delta > 0 \) and \( M_1 > 0 \) such that \( |h(x)| \leq M_1 |x|^p \) when \( |x| < \delta \). Let \( E_1 = \{|f| < 3\delta/4\} \). Since \( f_{i_{j_k}} \to f \) a.e. as \( k \to \infty \), for such \( \delta > 0 \), there exists \( N_1 > 0 \) such that \( |f_{i_{j_k}} - f| < \delta/4 \) a.e. whenever \( k > N_1 \). Thus, \( |f_{i_{j_k}}| < \delta \) a.e. on \( E_1 \). Hence, for such \( k \), \( |h \circ f_{i_{j_k}}| \leq M_1|f_{i_{j_k}}|^p \) a.e. on \( E_1 \). Since \( M_1 \int_{E_1} |f_{i_{j_k}}|^p \leq M_1 \|f_{i_{j_k}}\|_p^p < \infty \), by the dominated convergence theorem, we have

\[
\lim_{k \to \infty} \int_{E_1} h \circ f_{i_{j_k}} = \int_{E_1} h \circ f.
\]
On the other hand, there exist $M_0 > 0$ and $M_2 > 0$ such that, whenever $|x| > M_0$, we obtain $|h(x)| \leq M_2 |x|^p$. Let $E_2 = \{|f| > 3M_0/2\}$. Since $f_{ijk} \to f$ a.e. as $k \to \infty$, there exists $N_2 > 0$ for such $M_0 > 0$ such that $|f_{ijk} - f| < M_0/2$ a.e. whenever $k > N_2$. Thus, $|f_{ijk}| > M_0$ a.e. on $E_2$. Hence, for such $k$, $|h \circ f_{ijk}| \leq M_2 |f_{ijk}|^p$ a.e. on $E_2$. Since

$$M_2 \int_{E_2} |f_{ijk}|^p \leq M_2 \|f_{ijk}\|^p \leq CM_2 \|\nabla f_{ijk}\|^p < \infty,$$

by the dominated convergence theorem, we obtain

$$\lim_{k \to \infty} \int_{E_2} h \circ f_{ijk} = \int_{E_2} h \circ f.$$

Now let $E_3 = \mathbb{R}^n \setminus (E_1 \cup E_2)$ and $N = \max \{N_1, N_2\}$. Then, for $k > N$, we have $\delta/2 \leq |f_{ijk}| \leq 2M_0$ a.e. on $E_3$. Thus, for such $k$, since $h$ is continuous, there exists $\gamma > 0$ such that $|h \circ f_{ijk}| \leq \gamma |f_{ijk}|$ a.e. on $E_3$. Since

$$\gamma \int_{E_3} |f_{ijk}| \leq \gamma \|f_{ijk}\|_1 \leq \gamma \|f_{ijk}\|_p < \infty,$$

again by the dominated convergence theorem, we obtain

$$\lim_{k \to \infty} \int_{E_3} h \circ f_{ijk} = \int_{E_3} h \circ f.$$

3. $\text{SL}(n)$ invariance. Let $f \in W^{1,p}(\mathbb{R}^n)$ and $\phi \in \text{SL}(n)$. Then

$$z(f \circ \phi^{-1}) = \int_{\mathbb{R}^n} h \circ f \circ \phi^{-1} = \int_{\mathbb{R}^n} h \left(f \left(\phi^{-1}x\right)\right) \, dx.$$

By setting $y = \phi^{-1}x$, we obtain

$$z(f \circ \phi^{-1}) = \int_{\mathbb{R}^n} h \left(f(y)\right) \, dy = \int_{\mathbb{R}^n} h \circ f = z(f).$$

4. Translation invariance. Let $f \in W^{1,p}(\mathbb{R}^n)$ and $\tau$ be a translation. Then

$$z(f \circ \tau^{-1}) = \int_{\mathbb{R}^n} h \circ f \circ \tau^{-1} = \int_{\mathbb{R}^n} h \left(f \left(\tau^{-1}x\right)\right) \, dx.$$

By setting $y = \tau^{-1}x$, we obtain

$$z(f \circ \tau^{-1}) = \int_{\mathbb{R}^n} h \left(f(y)\right) \, dy = \int_{\mathbb{R}^n} h \circ f = z(f).$$
5. \( z(0) = 0 \). This fact follows from the continuity of \( z \) and (3).

6. Differentiability. Let \( \ell_P \in P^{1,p}(\mathbb{R}^n) \) where \( P \in P_0^n \). Without loss of generality, we assume \( s > 0 \). Indeed, set

\[
h^e(x) = \frac{h(x) + h(-x)}{2} \quad \text{and} \quad h^o(x) = \frac{h(x) - h(-x)}{2},
\]

for every \( x \in \mathbb{R} \), and the case \( s < 0 \) follows from

\[
z(-s\ell_P) = \int_{\mathbb{R}^n} (h^e + h^o) \circ (-s\ell_P)
\]

\[
= \int_{\mathbb{R}^n} (h^e \circ (-s\ell_P) + h^o \circ (-s\ell_P))
\]

\[
= \int_{\mathbb{R}^n} (h^e \circ (s\ell_P) - h^o \circ (s\ell_P)).
\]

Since \( h \in BV_{\text{loc}}(\mathbb{R}) \), there exists a signed measure \( \nu \) on \( \mathbb{R} \) such that \( h(s) = \nu([0,s)) \) for every \( s > 0 \) (this can be done by setting \( \nu = 1_{[0,s)} \) in (4)). By the layer cake representation, we have

\[
z(s\ell_P) = \int_{\mathbb{R}^n} h \circ (s\ell_P)
\]

\[
= \int_0^s \{|s\ell_P > t|\} \, d\nu(t) = |P| \int_0^s \left( \frac{s - t}{s} \right)^n \, d\nu(t).
\]

In other words, we obtain

\[
s^n z(s\ell_P) = |P| \int_0^s (s - t)^n \, d\nu(t).
\]

We will now show the differentiability by induction. Let \( k \geq 2 \) and \( \psi_k(s) \) be the \( k \)th derivative of \( \int_0^s (s - t)^n \, d\nu(t) \) with respect to \( s \). We have

\[
\psi_k(s) = \frac{n!}{(n-k)!} \int_0^s (s - t)^{n-k} \, d\nu(t).
\]

In particular, we obtain \( \psi_n(s) = n! h(s) \). On the other hand, differentiating the left hand side of (5) gives

\[
\psi_1(s) |P| = n s^{n-1} z(s\ell_P) + s^n Dz_{\ell_P}(s).
\]

By induction, it follows that

\[
\psi_k(s) |P| = \sum_{j=0}^k \binom{k}{j} \frac{n!}{(n-k+j)!} s^{n-k+j} D^j z_{\ell_P}(s).
\]
In particular, we obtain

\[ \psi_n(s) |P| = n! \sum_{j=0}^{n} \binom{n}{j} s^j D^j z_{\ell_P}(s), \]

which coincides with \( n! |P| h(s) \). Since \( h \) is a continuous locally \( BV \) function, we have the desired differentiability of \( s \mapsto z(s\ell_P) \).

7. Growth condition. First of all, by (5),

\[
z(s\ell_P) = |P| \int_0^s \left( \frac{s-t}{s} \right)^n d\nu(t) \leq |P| \int_0^s d\nu(t) = |P| h(s)
\]

satisfies (3). As shown in the previous steps ((6) and (7)), for every integer \( 1 \leq k \leq n \),

\[
\sum_{j=0}^{k} \binom{k}{j} \frac{n!}{(n-k+j)!} s^{n-k+j} D^j z_{\ell_P}(s) = \frac{n!}{(n-k)!} |P| \int_0^s (s-t)^{n-k} d\nu(t).
\]

That is

\[
\sum_{j=0}^{k} \binom{k}{j} \frac{n!}{(n-k+j)!} s^j D^j z_{\ell_P}(s) = \frac{n!}{(n-k)!} |P| \int_0^s \left( \frac{s-t}{s} \right)^{n-k} d\nu(t) \leq \frac{n!}{(n-k)!} |P| h(s)
\]

also satisfies (3).

\[\square\]

3. THE CHARACTERIZATION OF HOMOGENEOUS VALUATIONS

First, we need the following reduction similar to [23, Lemma 8]. We include the proof for the sake of completeness.

**Lemma 10.** Let \( z_1, z_2 : L^{1,p}(\mathbb{R}^n) \to \mathbb{R} \) be continuous and translation invariant valuations satisfying \( z_1(0) = z_2(0) = 0 \). If \( z_1(sf) = z_2(sf) \) for all \( s \in \mathbb{R} \) and \( f \in P^{1,p}(\mathbb{R}^n) \), then

\[ z_1(f) = z_2(f) \]

for all \( f \in L^{1,p}(\mathbb{R}^n) \).

**Proof.** We first make the following four reduction steps for (8).
1. We begin by considering all \( f \in L^{1,p}(\mathbb{R}^n) \) that are non-negative. Since \( z_1 \) and \( z_2 \) are valuations satisfying \( z_1(0) = z_2(0) = 0 \), we have for \( i = 1, 2, \)
\[
z_i(f \vee 0) + z_i(f \wedge 0) = z_i(f) + z_i(0) = z_i(f).
\]
For \( i = 1, 2, \) let
\[
z_i^e(f) = \frac{z_i(f) + z_i(-f)}{2}, \quad z_i^o(f) = \frac{z_i(f) - z_i(-f)}{2}
\]
and hence \( z_i(f) = z_i^e(f) + z_i^o(f) \) for all \( f \in L^{1,p}(\mathbb{R}^n) \). Therefore, we have
\[
z_i^e(f \wedge 0) = z_i^e((-(-f) \wedge 0)) = z_i^e((-f) \wedge 0)
\]
and
\[
z_i^o(f \wedge 0) = z_i^o((-(-f) \wedge 0)) = -z_i^o((-f) \wedge 0).
\]
Thus, it suffices to show that (8) holds for all non-negative \( f \in L^{1,p}(\mathbb{R}^n) \).

2. Next, let \( f \in L^{1,p}(\mathbb{R}^n) \) where the values \( f(v) \) are distinct for \( v \in V \) with \( f(v) > 0 \). Let \( f \) not vanish identically and \( S \) be the triangulation of the support of \( f \) in \( n \)-dimensional simplices such that \( f|_{\Delta} \) is affine for each simplex \( \Delta \in S \). Denote by \( V \) the (finite) set of vertices of \( S \). Note that \( f \) is determined by its value on \( V \). By the continuity of \( z_1 \) and \( z_2 \), we have the reduction as there always exists an approximation of \( f \) by \( g \in L^{1,p}(\mathbb{R}^n) \) where the values \( g(v) \) are distinct for \( v \in V \) with \( g(v) > 0 \).

3. We now consider all \( f \in L^{1,p}(\mathbb{R}^n) \) that are concave on their supports. Let \( f_1, \ldots, f_m \in L^{1,p}(\mathbb{R}^n) \) be non-negative and concave on their supports such that
\[
f = f_1 \vee \cdots \vee f_m.
\]
For \( i = 1, 2, \) by the inclusion-exclusion principle, we obtain
\[
z_i(f) = z_i(f_1 \vee \cdots \vee f_m) = \sum_{J} (-1)^{|J|-1} z_i(f_J),
\]
where \( J \) is a non-empty subset of \( \{1, \ldots, m\} \) and
\[
f_J = f_{j_1} \wedge \cdots \wedge f_{j_k},\]
for \( J = \{j_1, \ldots, j_k\} \). Indeed, such representation in (9) exists. We determine the \( f_i \)'s by their value on \( V \). Set \( f_i(v) = f(v) \) on the vertices \( v \) of the simplex \( \Delta_i \) of \( S \). Choose a polytope \( P_i \) containing \( \Delta_i \) and set \( f_i(v) = 0 \) on the vertices \( v \) of \( P_i \). If the \( P_i \)'s are chosen suitably small, (9) holds. The reduction follows since the meet of concave functions is still concave.

4. Then take all functions \( f \in L^{1,p}(\mathbb{R}^n) \) such that \( F \) defined below, is not singular. Given a function \( f \in L^{1,p}(\mathbb{R}^n) \), let \( F \subset \mathbb{R}^{n+1} \)
be the compact polytope bounded by the graph of \( f \) and the hyperplane \( \{ x_{n+1} = 0 \} \). We say \( F \) is singular if \( F \) has \( n \) facet hyperplanes that intersect in a line \( L \) parallel to \( \{ x_{n+1} = 0 \} \) but not contained in \( \{ x_{n+1} = 0 \} \). Similar to the second step, by continuity of \( z_1 \) and \( z_2 \), it suffices to show (8) for \( f \in L^{1,p}(\mathbb{R}^n) \) such that \( F \) is not singular.

Let a function \( f \) satisfying reduction steps 1-4 be given. Denote by \( \bar{p} \) the vertex of \( F \) with the largest \( x_{n+1} \)-coordinate. We are now going to show (8) by induction on the number \( m \) of facet hyperplanes of \( F \) that are not passing through \( \bar{p} \). In the case \( m = 1 \), a scaled translate of \( f \) is in \( P^{1,p}(\mathbb{R}^n) \). Since \( z_1 \) and \( z_2 \) are translation invariant, equation (8) holds. Let \( m \geq 2 \). Further let \( p_0 = (x_0, f(x_0)) \) be a vertex of \( F \) with minimal \( x_{n+1} \)-coordinate and \( H_1, \ldots, H_j \) be the facet hyperplanes of \( F \) through \( p_0 \) which do not contain \( \bar{p} \). Notice that there exists at least one such hyperplane. Write \( \bar{F} \) as the polytope bounded by the intersection of all facet hyperplanes of \( F \) other than \( H_1, \ldots, H_j \). Since \( F \) is not singular, \( \bar{F} \) is bounded. Thus, there exists an \( f \in L^{1,p}(\mathbb{R}^n) \) that corresponds to \( F \). Note that \( \bar{F} \) has at most \( (m-1) \) facet hyperplanes not containing \( \bar{p} \). Let \( \bar{H}_1, \ldots, \bar{H}_i \) be the facet hyperplanes of \( \bar{F} \) that contain \( p_0 \). Choose hyperplanes \( \bar{H}_{i+1}, \ldots, \bar{H}_k \) also containing \( p_0 \) such that the hyperplanes \( \bar{H}_1, \ldots, \bar{H}_k \) and \( \{ x_{n+1} = 0 \} \) enclose a pyramid with apex at \( p_0 \) that is contained in \( \bar{F} \) and has \( x_0 \) in its base with \( \bar{H}_1, \ldots, \bar{H}_i \) among its facet hyperplanes. Therefore, there exists a piecewise affine function \( \ell \) corresponding to this pyramid. Moreover, a scaled translate of \( \ell \) is in \( P^{1,p}(\mathbb{R}^n) \). We also obtain that a scaled translate of \( \tilde{\ell} = f \wedge \ell \) is in \( P^{1,p}(\mathbb{R}^n) \). To summarize, scaled translates of \( \tilde{\ell} \) and \( \ell \) are in \( P^{1,p}(\mathbb{R}^n) \), the polytope \( \bar{F} \) has at most \( (m-1) \) facet hyperplanes not containing \( \bar{p} \), and
\[
f \vee \ell = \tilde{f} \text{ and } f \wedge \ell = \tilde{\ell}.
\]
Applying valuations \( z_1 \) and \( z_2 \), we have, for \( i = 1, 2 \),
\[
z_i(f) + z_i(\ell) = z_i(\tilde{f}) + z_i(\tilde{\ell}).
\]
Thus, the induction hypotheses yields the desired result. \( \square \)

The classification will also make use of the following elementary fact.

**Remark 11.** Let \( f \) and \( g \) be functions on \( \mathbb{R} \). If \( f(x) \sim o(g(x)h(x)) \) as \( x \to 0 \), for each function \( h \) on \( \mathbb{R} \) with \( \lim_{x \to 0} h(x) = \infty \), then
\[
f(x) \sim O(g(x)) \text{ as } x \to 0.
\]
This can be seen by the following simple argument. Suppose \( |f(x)/g(x)| \to \infty \) as \( x \to 0 \). Let \( h = \sqrt{|f/g|} \). It is clear that \( h(x) \to \infty \) as \( x \to 0 \).
But now

\[ |f(x)/(g(x)h(x))| = \sqrt{|f(x)/g(x)|} = h(x) \to \infty \text{ as } x \to 0, \]

which yields a contradiction. A similar argument also works for the limit as \( x \to \infty \).

**Lemma 12.** Let \( z : L^{1,p}(\mathbb{R}^n) \to \mathbb{R} \) be a continuous, \( SL(n) \) and translation invariant valuation with \( z(0) = 0 \). Then there exists a continuous function \( c : \mathbb{R} \to \mathbb{R} \) satisfying (3) such that

\[ z(s\ell) = c(s)|P|, \]

for every \( s \in \mathbb{R} \) and \( \ell \in P^{1,p}(\mathbb{R}^n) \).

**Proof.** Similar to the proof of Lemma 5 in [23]. Define the functional \( Z : \mathcal{P}_0^n \to \mathbb{R} \) by setting

\[ Z(P) = z(s\ell), \]

for every \( s \in \mathbb{R} \) and \( \ell \in P^{1,p}(\mathbb{R}^n) \). If \( \ell_P, \ell_Q \in P^{1,p}(\mathbb{R}^n) \) are such that \( \ell_P \lor \ell_Q \in P^{1,p}(\mathbb{R}^n) \), then \( \ell_P \lor \ell_Q = \ell_{P\cup Q} \) and \( \ell_P \land \ell_Q = \ell_{P\cap Q} \). Since \( z \) is a valuation on \( L^{1,p}(\mathbb{R}^n) \), it follows that

\[
Z(P) + Z(Q) = z(s\ell_P) + z(s\ell_Q) = z(s(\ell_P \lor \ell_Q)) + z(s(\ell_P \land \ell_Q)) = Z(P \cup Q) + Z(P \cap Q),
\]

for \( P, Q, P \cup Q \in \mathcal{P}_0^n \). Thus, \( Z : \mathcal{P}_0^n \to \mathbb{R} \) is a valuation.

By Theorem 1, there exist \( c_0, c_1, c_2 \in \mathbb{R} \) depending now on \( s \) such that

\[ z(s\ell) = c_0(s) + c_1(s)|P| + c_2(s)|P^*|, \]

for all \( s \in \mathbb{R} \) and \( \ell \in P^{1,p}(\mathbb{R}^n) \). We now investigate the behavior of these constants by studying valuations on different \( s\ell \)'s and their translations, for \( s \in \mathbb{R} \).

We start with \( c_0 \) and \( c_2 \).

**Example 1.** Let \( P \in \mathcal{P}_0^n \). Take translations \( \tau_1, \ldots, \tau_k \) such that the \( \phi_i \)’s are pairwise disjoint, where \( \phi_i = \tau_i(P/k^i) \). Consider the function \( f_k = s(\ell_{\phi_1} \lor \cdots \lor \ell_{\phi_k}) \), \( s \in \mathbb{R} \). Then, we have

\[
\|f_k\|^p_{p} = |s|^p \sum_{i=1}^{k} \int_{\phi_iP} \ell_{\phi_i}^p = |s|^p \sum_{i=1}^{k} \int_{\phi_iP} (\ell_{P}(\phi_i^{-1}x))^p dx
\]

\[
= |s|^p \sum_{i=1}^{k} k^{-in} \int_{P} \ell_{P}^p = |s|^p \|\ell_{P}\|^p_{p} \sum_{i=1}^{k} k^{-in} \to 0 \text{ as } k \to \infty.
\]
Thus, \( \ell P \) and \( c \)

Therefore, \( c \)

\[ \| \nabla f_k \|_p^p = |s|^p \sum_{i=1}^{k} \left| \nabla \ell \phi_i, P \right|^p = |s|^p \sum_{i=1}^{k} \left| \nabla (\ell P \circ \phi_i^{-1}) \right|^p \]

\[ = |s|^p \sum_{i=1}^{k} \int_{\phi_i, P} \left| \phi_i^{-1} \nabla \ell P (\phi_i^{-1} x) \right|^p dx = |s|^p \sum_{i=1}^{k} k^{ip} \int_{\phi_i, P} \left| \nabla \ell P (\phi_i^{-1} x) \right|^p dx \]

\[ = |s|^p \sum_{i=1}^{k} k^{-i(n-p)} \| \nabla \ell P \|_p^p \to 0 \text{ as } k \to \infty. \]

Thus, \( f_k \to 0 \) in \( W^{1,p}(\mathbb{R}^n) \) as \( k \to \infty. \)

By the translation invariance of \( z \) and (10), we have

\[ z(f_k) = \sum_{i=1}^{k} z(s \ell_{P/k/s}) = \sum_{i=1}^{k} \left( c_0(s) + \frac{c_1(s)}{k|m} |P| + c_2(s) k^m |P^*| \right) \]

\[ = kc_0(s) + c_1(s) |P| \sum_{i=1}^{k} k^{-in} + c_2(s) |P^*| \sum_{i=1}^{k} k^m \to 0 \text{ as } k \to \infty. \]

Therefore, \( c_2(s) \) has to vanish as the geometric series diverges, as well as \( c_0(s) \), for every \( s \in \mathbb{R}. \)

Now, let’s further determine \( c_1 \) by two different examples.

**Example 2.** For each function \( f \) with \( \lim_{x \to 0} f(x) = \infty \), let \( P \in \mathcal{P}_0^n \) and \( P_k = P (k^p / f(1/k))^{\frac{1}{n}} \), for \( k = 1, 2, \ldots \). Then, we have

\[ \| \ell_{P_k} / k \|_p^p = c_{n,p} k^{-p} \| P_k \| = c_{n,p} |P| / f(1/k) \to 0 \text{ as } k \to \infty \]

and

\[ \| \nabla \ell_{P_k} / k \|_p^p = \frac{1}{n} k^{-p} S_p(P_k) = \frac{1}{n} S_p(P) k^{-\frac{n^2}{n}} (f(1/k))^{\frac{n-n^2}{n^2}} \to 0 \text{ as } k \to \infty. \]

Thus, \( \ell_{P_k} / k \to 0 \) in \( W^{1,p}(\mathbb{R}^n) \) as \( k \to \infty. \)

By (10), we obtain

\[ z(\ell_{P_k} / k) = c_1(1/k) k^{p} |P| / f(1/k) \to 0 \text{ as } k \to \infty. \]

Therefore, \( c_1(1/k) \sim o(f(1/k) / k^p) \) as \( k \to \infty. \) Similarly, considering \( -\ell_{P_k} / k \), we obtain the same estimate as \( x \to 0^- \). Hence, \( c_1(x) \sim o(x^p f(x)) \) as \( x \to 0. \) It follows that \( c_1(x) \sim O(x^p) \) as \( x \to 0 \) via Remark 11.

**Example 3.** For each function \( f \) with \( \lim_{x \to \infty} f(x) = \infty \), let \( P \in \mathcal{P}_0^n \) and \( P_k = P / (k^p f(k))^{\frac{1}{n}} \), for \( k = 1, 2, \ldots \). Then, we have

\[ ||k \ell_{P_k}||_p^p = c_{n,p} k^p \| P_k \| = c_{n,p} k^{p-p^*} (f(k))^{-1} |P| \to 0 \text{ as } k \to \infty \]
and
\[
\|\nabla k \ell_{P_k}\|_p^p = \frac{1}{n} k^p S_p(P_k) = \frac{1}{n} S_p(P) (f(k))^{\frac{p-n}{n}} \to 0 \text{ as } k \to \infty.
\]

Thus, \(k \ell_{P_k} \to 0\) in \(W^{1,p}(\mathbb{R}^n)\) as \(k \to \infty\).

By (10), we obtain
\[
z(k \ell_{P_k}) = c_1(k) k^{-p^*} (f(k))^{-1} |P| \to 0 \text{ as } k \to \infty.
\]

Therefore, \(c_1(k) \sim o(k^{p^*} f(k))\) as \(k \to \infty\). Similarly, considering \(-k \ell_{P_k}\), we obtain the same estimate as \(x \to -\infty\). Hence, \(c_1(x) \sim o(x^{p^*} f(x))\) as \(x \to \infty\). It follows that \(c_1(x) \sim O(x^{p^*})\) as \(x \to \infty\) via Remark 11. \(\square\)

Now we are ready to prove the result on homogeneous valuations.

**Proof of Theorem 4.** The backwards direction has already been shown in Theorem 9.

We now consider the forward direction. In the light of Lemma 10, it suffices to consider the case \(f = s \ell_{P}\) for every \(s \in \mathbb{R}\) and \(\ell_{P} \in P^{1,p}(\mathbb{R}^n)\).

In this case, due to Lemma 12, there exists a continuous function \(c : \mathbb{R} \to \mathbb{R}\) satisfying (3) such that

\[
(11) \quad z(s \ell_{P}) = c(s) |P|
\]

for every \(s \in \mathbb{R}\) and \(\ell_{P} \in P^{1,p}(\mathbb{R}^n)\). On the other hand, by homogeneity, there exists a constant \(c \in \mathbb{R}\) such that

\[
(12) \quad z(s \ell_{P}) = c |s|^q |P|
\]

for every \(s \in \mathbb{R}\) and \(\ell_{P} \in P^{1,p}(\mathbb{R}^n)\). Formulas (11) and (12) yield

\[
(13) \quad c(s) = c |s|^q
\]

for every \(s \in \mathbb{R}\).

For \(q < p\) or \(q > p^*\), since \(c(s)\) satisfies (3), which is impossible with the expression (13), we have \(c = 0\). It follows that \(z(s \ell_{P}) = 0\) for every \(s \in \mathbb{R}\) and \(\ell_{P} \in P^{1,p}(\mathbb{R}^n)\).
For \( p \leq q \leq p^* \), set \( \tilde{c} = \binom{n+q}{q} c \). By properties of the beta and the gamma function and the layer cake representation, we have

\[
c(s) = \tilde{c} |s|^q \left( \binom{n+q}{q} \right)^{-1} \\
= \tilde{c} q |s|^q \frac{\Gamma(q) \Gamma(n+1)}{\Gamma(n+q+1)} \\
= \tilde{c} q |s|^q \int_0^1 t^{q-1} (1-t)^n dt \\
= \tilde{c} q \int_0^1 (|s| t)^{q-1} (1-t)^n |s| t \\
= \tilde{c} q \int_0^{|s|} t^{q-1} \left( \frac{|s| - t}{|s|} \right)^n dt.
\]

Thus,

\[
c(s) |P| = \tilde{c} q \int_0^{|s|} t^{q-1} |\{ |s| \ell_P > t \}| dt \\
= \tilde{c} \int_{\mathbb{R}^n} (|s| \ell_P(x))^q dx \\
= \tilde{c} \|s \ell_P\|_q^q.
\]

\( \square \)

4. A more general characterization

We finish the proof of Theorem 5 by the following crucial representation.

**Lemma 13.** Let the functional \( z : L^{1,p}(\mathbb{R}^n) \to \mathbb{R} \) satisfy \( z(0) = 0 \) and let \( s \mapsto z(sf) \) belong to \( B_p \) for \( s \in \mathbb{R} \) and \( \ell_P \in P^{1,p}(\mathbb{R}^n) \). If there exists a continuous function \( c : \mathbb{R} \to \mathbb{R} \) satisfying (3) such that

\[
z(s \ell_P) = c(s) |P|,
\]

for every \( s \in \mathbb{R} \) and \( \ell_P \in P^{1,p}(\mathbb{R}^n) \), then there exists a continuous function \( h \in G_p \) such that

\[
z(s \ell_P) = \int_{\mathbb{R}^n} h \circ (s \ell_P).
\]

**Proof.** It suffices to consider the case \( s > 0 \). Since there exists a continuous function \( c : \mathbb{R} \to \mathbb{R} \) satisfying (3), such that

\[
z(s \ell_P) = c(s) |P|,
\]
we have
\[
Dz_{\ell_P}(s) = c'(s) |P|.
\]
It follows that \(c(s)\) is continuously differentiable in the usual sense. Hence \(c(s) \in C^n(\mathbb{R})\), due to \(s \mapsto z(sf)\) belonging to \(C^n(\mathbb{R})\) for every \(s \in \mathbb{R}\) and \(f \in P^1_p(\mathbb{R}^n)\). Moreover,
\[
D^\alpha z_{\ell_P}(s) = c^{(\alpha)}(s) |P|,
\]
for every non-negative integer \(\alpha \leq n\) and \(c^{(n)} \in BV_{loc}(\mathbb{R})\).

Now, let
\[
h(s) = \sum_{j=0}^{n} \frac{1}{j!} \binom{n}{j} s^j c^{(j)}(s).
\]
We show by induction that there exists a signed measure \(\nu\) on \(\mathbb{R}\) such that
\[
c(s) = \int_0^s \left( \frac{s-t}{s} \right)^n d\nu(t).
\]
Since \(c \in C^n(\mathbb{R})\) and \(c^{(n)} \in BV_{loc}(\mathbb{R})\), there exists a signed measure \(\nu\) on \(\mathbb{R}\) such that \(h(s) = \nu([0,s])\) for every \(s \geq 0\). Let \(h_1(s) = \int_0^s h(x)dx\). Then, by Fubini’s theorem, we obtain
\[
h_1(s) = \int_0^s \int_0^x d\nu(t)dx = \int_0^s \int_t^x dx d\nu(t) = \int_0^s (s-t)d\nu(t).
\]
Let \(k \geq 2\) and \(h_k(s) = \int_0^s h_{k-1}(x)dx\). Assume \(h_k(x) = \frac{1}{k!} \int_0^x (x-t)^k d\nu(t)\). Applying Fubini’s theorem again gives
\[
h_{k+1}(s) = \frac{1}{k!} \int_0^s \int_0^x (x-t)^k d\nu(t)dx = \frac{1}{k!} \int_0^s \int_t^x (x-t)^k dx d\nu(t) = \frac{1}{(k+1)!} \int_0^s (s-t)^{k+1} d\nu(t).
\]
Thus, in particular, we have
\[
h_n(s) = \frac{1}{n!} \int_0^s (s-t)^n d\nu(t).
\]
On the other hand, by (15), we have

\[
\begin{align*}
  h(x) &= c(x) + \frac{1}{n!} x^n c^{(n)}(x) + \sum_{j=1}^{n-1} \frac{1}{j!} \left( \left( \binom{n-1}{j} + \binom{n-1}{j-1} \right) x^j c^{(j)}(x) ight) \\
  &= \sum_{j=0}^{n-1} \frac{1}{j!} \binom{n-1}{j} x^j c^{(j)}(x) + \sum_{j=0}^{n-1} \frac{1}{(j+1)!} \binom{n-1}{j} x^{j+1} c^{(j+1)}(x) \\
  &= \sum_{j=0}^{n-1} \frac{1}{(j+1)!} \binom{n-1}{j} (x^j c^{(j)}(x))'.
\end{align*}
\]

Hence,

\[
\begin{align*}
  h_1(s) &= \int_0^s h(x) \, dx = \sum_{j=0}^{n-1} \frac{1}{(j+1)!} \binom{n-1}{j} s^{j+1} c^{(j)}(s).
\end{align*}
\]

Assume that \( h_k(x) = \sum_{j=0}^{n-k} \frac{1}{(j+k)!} \binom{n-k}{j} x^{j+k} c^{(j)}(x) \). Similarly, we obtain

\[
\begin{align*}
  h_k(x) &= \frac{1}{k!} x^k c(x) + \frac{1}{n!} x^n c^{(n-k)}(x) \\
  &\quad + \sum_{j=1}^{n-k-1} \frac{1}{(j+k)!} \left( \left( \binom{n-k-1}{j} + \binom{n-k-1}{j-1} \right) x^j c^{(j)}(x) ight) \\
  &= \sum_{j=0}^{n-k-1} \frac{1}{(j+k)!} \binom{n-k-1}{j} x^j c^{(j)}(x) \\
  &\quad + \sum_{j=0}^{n-k-1} \frac{1}{(j+k+1)!} \binom{n-k-1}{j} x^{j+1} c^{(j+1)}(x) \\
  &= \sum_{j=0}^{n-k-1} \frac{1}{(j+k+1)!} \binom{n-k-1}{j} (x^{j+1} c^{(j)}(x))'.
\end{align*}
\]

It follows that

\[
\begin{align*}
  h_{k+1}(s) &= \int_0^s h_k(x) \, dx = \sum_{j=0}^{n-(k+1)} \frac{1}{(j+k+1)!} \binom{n-(k+1)}{j} s^{j+k+1} c^{(j)}(s).
\end{align*}
\]
Thus, in particular, we have $h_n(s) = \frac{1}{n!} s^n c(s)$. Therefore, by the layer cake representation, we have

$$z(s\ell_P) = c(s)|P| = \int_0^s \left(\frac{s-t}{s}\right)^n |P| \, d\nu(t)$$

$$= \int_0^s |\{s\ell_P > t\}| \, d\nu(t)$$

$$= \int_{\mathbb{R}^n} h \circ (s\ell_P).$$

Furthermore, for fixed $P \in \mathcal{P}_n^0$,

$$s^k D^k z_{\ell_P}(s) = s^k c^{(k)}(s) |P|$$

satisfies (3) for every integer $0 \leq k \leq n$. Therefore, as defined in (15), $h$ also satisfies (3).

Theorem 5 follows as an immediate corollary of Theorem 9 and Lemmas 10, 12, and 13.

Acknowledgement. The author wishes to thank the referees for valuable suggestions and careful reading of the original manuscript. The work of the author was supported in part by Austrian Science Fund (FWF) Project P23639-N18 and the National Natural Science Foundation of China Grant No. 11371239.
