Non-explosion of diffusion processes on manifolds with
time-dependent metric

Kazumasa Kuwada* and Robert Philipowski

Abstract

We study the problem of non-explosion of diffusion processes on a manifold with time-
dependent Riemannian metric. In particular we obtain that Brownian motion cannot explode
in finite time if the metric evolves under backwards Ricci flow. Our result makes it possible
to remove the assumption of non-explosion in the pathwise contraction result established by
Arnaudon, Coulibaly and Thalmaier (arXiv:0904.2762, to appear in Sém. Prob.).

As an important tool which is of independent interest we derive an Itô formula for the
distance from a fixed reference point, generalising a result of Kendall (Ann. Prob. 15 (1987),
1491–1500).

Keywords: Ricci flow, diffusion process, non-explosion, radial process.
AMS subject classification: 53C21, 53C44, 58J35, 60J60.

1 Brownian motion with respect to time-changing Riemannian
metrics

Let $M$ be a $d$-dimensional differentiable manifold, $\pi : \mathcal{F}(M) \to M$ the frame bundle and
$(g(t))_{t \in [0,T]}$ a family of Riemannian metrics on $M$ depending smoothly on $t$ such that $(M, g(t))$
is geodesically complete for all $t \in [0,T]$. Let $(e_i)_{i=1}^d$ be the standard basis of $\mathbb{R}^d$. For each$t \in [0,T]$ let $(H_i(t))_{i=1}^d$ be the associated $g(t)$-horizontal vector fields on $\mathcal{F}(M)$ (i.e. $H_i(t, u)$
is the $g(t)$-horizontal lift of $ue_i$), and let $(V_{\alpha,\beta})_{\alpha,\beta=1}^d$ be the canonical vertical vector fields. Let
$(W_t)_{t \geq 0}$ be a standard $\mathbb{R}^d$-valued Brownian motion. In this situation Arnaudon, Coulibaly and
Thalmaier [1, 5] defined horizontal Brownian motion on $\mathcal{F}(M)$ as the solution of the following
Stratonovich SDE:

$$dU_t = \sum_{i=1}^d H_i(t, U_t) \circ dW_t^i - \frac{1}{2} \sum_{\alpha,\beta=1}^d \frac{\partial g}{\partial t}(t, U_te_\alpha, U_te_\beta)V_{\alpha,\beta}(U_t)dt.$$  

They showed that if $U_0 \in \mathcal{O}_{g(0)}(M)$, then $U_t \in \mathcal{O}_{g(t)}(M)$ for all $t \in [0,T]$. $g(t)$-Brownian motion
on $M$ is then defined as $X_t := \pi U_t$. We denote the law of $g(t)$-Brownian motion on $M$ started
at $x$ by $P^x$, and expectation with respect to that measure by $E^x$.

2 Main result

The main result of this paper is the following theorem:

*Partially supported by the JSPS fellowship for research abroad
Theorem 1. If the family of metrics evolves under backwards super Ricci flow, i.e.
\[
\frac{\partial g}{\partial t} \leq \text{Ric},
\]  
then Brownian motion on \( M \) cannot explode up to time \( T \). In particular this result holds for backwards Ricci flow \( \frac{\partial g}{\partial t} = \text{Ric} \).

By recent work (see section 3), it has turned out that backwards Ricci flow tends to compensate the effects of Ricci curvature on the behaviour of heat flow and Brownian motion. Thus our result is quite natural because a lower bound of Ricci curvature yields the non-explosion property in the fixed metric case.

Remark 1.
1. In Section 6 we will give an extension of Theorem 1 including the case of non-symmetric diffusion processes.
2. For the question of explosion or non-explosion of Brownian motion on a manifold equipped with a fixed Riemannian metric see e.g. [6], [8, Section 7.8] or [9, Section 4.2].

As an important tool we prove the following Itô formula for the radial process \( \rho(t, X_t) \), where \( \rho(t, x) \) denotes the distance with respect to \( g(t) \) between \( x \) and a fixed reference point \( o \):

Theorem 2. There exists a non-decreasing continuous process \( L \) which increases only when \( X_t \in \text{Cut}_{g(t)}(o) \) such that
\[
\rho(t, X_t) = \rho(0, X_0) + \int_0^t \left[ \frac{1}{2} \Delta_{g(s)} \rho + \frac{\partial \rho}{\partial s} \right] (s, X_s) ds + \sum_{i=1}^d \int_0^t (U_s e_i) \rho(s, X_s) dW_s^i - L_t. \tag{2}
\]

Remark 2.
1. The usual Itô formula fails to apply because the distance function is not smooth at the cut-locus. A priori it is even not clear that \( \rho(t, X_t) \) is a semimartingale.
2. In the case of a fixed Riemannian metric Theorem 2 was proved by Kendall [11] (see also [8, Theorem 7.254] or [9, Theorem 3.5.1]). The idea of our proof is based on Kendall’s original one.

3 Remarks concerning related work

McCann and Topping [13] (see Topping [15] and Lott [12] also) showed contraction in the Wasserstein metric for the heat equation under backwards Ricci flow on a compact manifold. More precisely, they showed that the following are equivalent:

1. \( g \) evolves under backwards super Ricci flow, i.e. \( \frac{\partial g}{\partial t} \leq \text{Ric} \).
2. Whenever \( u \) and \( v \) are two non-negative unit-mass solutions of the heat equation
\[
\frac{\partial u}{\partial t} = \frac{1}{2} \Delta_{g(t)} u - \left( \frac{1}{2} \text{tr} \frac{\partial g}{\partial t} \right) u
\]
(the term \( \left( \frac{1}{2} \text{tr} \frac{\partial g}{\partial t} \right) u \) comes from the change in time of the volume element), the function \( t \mapsto W_2(t, u(t, \cdot) \text{vol}_{g(t)}, v(t, \cdot) \text{vol}_{g(t)}) \) is non-increasing. Here
\[
W_2(t, \mu, \nu) := \left( \inf_{\pi} \int_{M \times M} d_{g(t)}(x, y)^2 \pi(dx, dy) \right)^{1/2}
\]
is the $L^2$-Wasserstein distance of two probability measures $\mu$ and $\nu$ on $M$. (The infimum is over all probability measures $\pi$ on $M \times M$ whose marginals are $\mu$ and $\nu$.)

It means that backwards super Ricci flow is characterised by the contractivity property for solutions of the heat equation. Moreover, in recent work by Topping [15] and Lott [12] (see Brendle [3] also) the heat equation and the theory of optimal transport are efficiently used to derive several monotonicity results including a new proof for the monotonicity of Perelman’s reduced volume. These facts indicate that it would be effective for deeper understanding of Ricci flow to study the heat equation in conjunction with backwards Ricci flow and the theory of optimal transport.

The non-explosion property of the Brownian motion is one of the first problems we face when we begin to consider the heat equation on a noncompact manifold. Our result tells us that it is always satisfied as far as we consider the heat equation under backwards Ricci flow. It will be quite helpful for the study of Ricci flow on a noncompact manifold by means of the heat equation. In fact, our result enables us to remove the assumption on the non-explosion in recent work by Arnaudon, Coulibaly and Thalmaier [2, Section 4]. They extend McCann and Topping’s implication $1 \Rightarrow 2$ in the case on a noncompact manifold. In addition, they sharpen the monotonicity of $L^2$-Wasserstein distance to a pathwise contraction in the following sense; There is a coupling $(\bar{X}^{(1)}_t, \bar{X}^{(2)}_t)_{t \geq 0}$ of two Brownian motions starting from $x, y \in X$ respectively so that $t \mapsto d_g(t)(\bar{X}^{(1)}_t, \bar{X}^{(2)}_t)$ is non-increasing almost surely. By taking an expectation, we can derive the monotonicity of the $L^2$-Wasserstein distance from it. The sharpness of their pathwise contraction looks useful for the study of the optimal transport associated with a more general cost function than the squared distance, e.g. $L^{\infty}$-optimal transportation studied in the above mentioned papers [15, 12, 3]. As a consequence of our result, we can consider such a problem without assuming the compactness of the underlying space.

4 Proof of Theorem 2: Itô’s formula for the radial process

Since it suffices to prove Theorem 2 before the exit time of $X$ of an arbitrarily large relatively compact open subset of $M$, we may assume that $M$ is compact and that therefore its injectivity radius

$$i_M := \inf \{d_g(t)(x, y) \mid t \in [0, T], y \in \text{Cut}_g(t)(x)\}$$

is strictly positive and that we have a uniform bound for the sectional curvature $\text{Sect}_g(t)$:

$$|\text{Sect}_g(t)| \leq K^2 \quad \text{for all } t \in [0, T].$$

We first state Itô’s formula for smooth functions:

**Lemma 1.** Let $f$ be a smooth function on $[0, T] \times M$. Then

$$df(t, X_t) = \frac{\partial f}{\partial t}(t, X_t)dt + \frac{1}{2} \Delta_g(t)f(t, X_t)dt + \sum_{i=1}^{d}(U_t e_i)f(t, X_t) dW^i_t.$$

**Proof.** Itô’s formula applied to a smooth function $\tilde{f}$ on $[0, T] \times \mathcal{F}(M)$ gives

$$d\tilde{f}(t, U_t) = \frac{\partial \tilde{f}}{\partial t}(t, U_t)dt + \sum_{i=1}^{d} H_i(t)\tilde{f}(t, U_t) dW^i_t + \frac{1}{2} \sum_{i=1}^{d} H_i(t)^2 \tilde{f}(t, U_t) dt$$

$$- \frac{1}{2} \sum_{\alpha, \beta = 1}^{d} \frac{\partial g}{\partial t}(t, U_t e_\alpha, U_t e_\beta) V_{\alpha \beta} \tilde{f}(t, U_t) dt.$$

(3)
Now let \( \tilde{f}(t, u) := f(t, \pi u) \). By definition of \( H_i(t) \), \( H_i(t) \tilde{f}(t, u) = (ue_i) f(t, \pi u) \). Moreover, it is well known (see e.g. [3 Proposition 3.1.2]) that \( \sum_{i=1}^{d} H_i(t)^2 \tilde{f}(t, u) = \Delta_{g(t)} f(t, \pi u) \). Finally, since \( \tilde{f} \) is constant in the vertical direction, the last term in [3] vanishes, so that the claim follows.

\[ \]

**Lemma 2.** Let \( G(x, \tau, y, t) \) (\( x, y \in M \), \( 0 \leq t < \tau \leq T \)) be the fundamental solution of the equation \( \frac{\partial u}{\partial t} = \frac{1}{2} \Delta_{g(t)} u \) (see [7] for existence). Then for all \( \tau \in (0, T] \) and all \( x \in M \) the law of \( X_\tau \) under \( P^x \) is absolutely continuous with respect to the volume measure (note that this property does not depend on the choice of the Riemannian metric), and its density with respect to the \( g(0) \)-volume measure is given by \( y \mapsto G(x, \tau, y, 0) \).

**Proof.** Fix \( \varphi \in C^2(M) \), and let \( u \) be the solution of the initial value problem

\[
\begin{aligned}
&\frac{\partial u}{\partial t} = \frac{1}{2} \Delta_{g(t)} u \\
&u(0, \cdot) = \varphi.
\end{aligned}
\]

Then by Corollary 2.2 in [7],

\[
u(\tau, x) = \int_M G(x, \tau, y, 0) \varphi(y) dv_{g(0)}(y).
\]

Now apply Itô’s formula to \( X \) and the function \( (t, x) \mapsto u(\tau - t, x) \) to obtain

\[
u(0, X_\tau) = u(\tau, X_0) - \int_0^\tau \frac{\partial u}{\partial t}(\tau - t, X_t) dt + \frac{1}{2} \int_0^\tau \Delta_{g(t)} u(\tau - t, X_t) dt + \text{martingale}
\]

so that

\[
E^x [\varphi(X_\tau)] = E^x [u(0, X_\tau)] = E^x [u(\tau, X_0)] = u(\tau, x) = \int_M G(x, \tau, y, 0) \varphi(y) dv_{g(0)}(y).
\]

Since \( \varphi \) is arbitrary the claim is proved.

\[ \]

**Lemma 3.** \( \{ t \in [0, T] \mid X_t \in \text{Cut}_{g(t)}(o) \} \) has Lebesgue measure zero almost surely.

**Proof.** Since by Lemma 2 for each \( t \in (0, T] \) and any starting point \( x \in M \), the law of \( X_t \) under \( P^x \) is absolutely continuous with respect to the volume measure, and since moreover the cut-locus \( \text{Cut}_{g(t)}(o) \) has \( g(t) \)-volume zero (see e.g. [8 Theorem 7.253] or [4 Proposition 3.1]), we have

\[
E^x \left[ \int_0^T 1_{\{X_t \in \text{Cut}_{g(t)}(o)\}} dt \right] = \int_0^T P^x \left[ X_t \in \text{Cut}_{g(t)}(o) \right] dt = 0,
\]

so that almost surely \( \int_0^T 1_{\{X_t \in \text{Cut}_{g(t)}(o)\}} dt = 0 \).

\[ \]

We now apply Lemma 1 to the process \( \rho(t, X_t) \) up to singularity. As long as \( X_t \) stays away from \( o \) and the \( g(t) \)-cut-locus of \( o \),

\[
d\rho(t, X_t) = d\beta_t + \frac{1}{2} \left[ \Delta_{g(t)} \rho + 2 \frac{\partial \rho}{\partial t} \right](t, X_t) dt,
\]

where \( \beta_t \) is the martingale term given by

\[
\beta_t := \sum_{i=1}^{d} \int_0^t H_i(s) \rho(s, U_s) dW^i_s.
\]
As we will observe in Lemma 5, the singularity of $\rho(t,x)$ at $o$ is negligible. The quadratic variation $\langle \beta \rangle_t$ of $\beta_t$ is computed as follows:

$$\langle \beta \rangle_t = \sum_{i=1}^{d} \int_0^t [H_i(s) \dot{\rho}(s, U_s)]^2 \, ds$$

$$= \sum_{i=1}^{d} \int_0^t [(U_s e_i) \rho(s, X_s)]^2 \, ds$$

$$= \int_0^t |\nabla g(s) \rho(s, X_s)|^2 \, ds$$

$$= t.$$

Thus $\beta_t$ is a standard one-dimensional Brownian motion.

**Lemma 4** (Lemma 5 and Remark 6 in [13]). The function $(t,x) \mapsto \rho(t,x)$ is smooth whenever $x \notin \{o\} \cup \text{Cut}_{g(t)}(o)$, and

$$\frac{\partial \rho}{\partial t}(t,x) = \frac{1}{2} \int_0^t \rho(t,x) \frac{\partial g}{\partial t}(\dot{\gamma}(s), \dot{\gamma}(s)) \, ds,$$

where $\gamma : [0, \rho(t,x)] \to M$ is the unique minimizing unit-speed $g(t)$-geodesic joining $o$ to $x$.

Let $\text{Cut}_{ST}$ be the space-time cut-locus defined by

$$\text{Cut}_{ST} := \{(t,x,y) \in [0,T] \times M \times M \mid (x,y) \in \text{Cut}_{g(t)}\}.$$

It is shown in [13] that $\text{Cut}_{ST}$ is a closed subset in $[0,T] \times M \times M$. Though they assumed $M$ to be compact, extension to the noncompact case is straightforward. Since $[0,T] \times \{o\} \times \{o\}$ is a closed subset in $[0,T] \times M \times M$ and it is away from $\text{Cut}_{ST}$, we can take $r_1 > 0$ so that

$$d_{g(t)}(o, \text{Cut}_{g(t)}(o)) > r_1$$

(5)

holds for all $t \in [0,T]$. Thus we can use (4) when $X_t$ is in a small neighbourhood of $o$ until $X_t$ hits $o$. Since $g(t)$ is smooth, Lemma 4 and (4) together with the Laplacian comparison theorem imply the following by a standard argument:

**Lemma 5.** With probability one, $X_t$ never hits $o$.

For $x, y \in M$, let

$$\overline{d}(x,y) := \sup_{t \in [0,T]} d_{g(t)}(x,y).$$

We consider $[0,T] \times M \times M$ equipped with the distance function $d((s,x_1,x_2),(t,y_1,y_2)) := \max\{|t-s|, \overline{d}(x_1,y_1), \overline{d}(x_2,y_2)\}$.

By Lemma 4 and the compactness of $M$, there exists a constant $C_1 > 0$ such that

$$|d_{g(t)}(x,y) - d_{g(t')}(x,y)| \leq C_1 |t-t'|$$

(6)

holds for any $t, t' \in [0,T]$ and $x, y \in M$. We now define a set $A$ by

$$A := \left\{(t,x,y) \in [0,T] \times M \times M \mid d_{g(t)}(o,x) \geq 2i_{M}/3, d_{g(t)}(o,y) = i_{M}/3 \text{ and } d_{g(t)}(x,y) = d_{g(t)}(o,x) - d_{g(t)}(o,y) \right\}.$$
Note that $A$ is closed and hence compact since $d_{g(t)}(x,y)$ is continuous as a function of $(t,x,y)$. Note that, for $(t,x,y) \in A$, $y$ is on a minimal $g(t)$-geodesic joining $o$ and $x$. In particular, symmetry of the cut locus implies that $A \cap \text{Cut}_{ST} = \emptyset$. Thus we have

$$\delta_1 := d(A, \text{Cut}_{ST}) \geq \frac{i_M}{3(C_1 + 1)} > 0.$$ 

We define the function $V : \mathbb{R}_+ \to \mathbb{R}_+$ by

$$V(r) := \frac{d - 1}{2} K \coth \left( K \cdot r \wedge \frac{i_M}{3} \right) + 2C_1.$$ 

The Laplacian comparison theorem implies that, for all $(t,x,y) \notin \text{Cut}_{ST}$, $|\Delta_{g(t)}(d_{g(t)}(y,\cdot)(x))| \leq (d - 1)K \coth(Kd_{g(t)}(x,y))$ and hence Lemma 3 implies

$$\left| \frac{1}{2}(\Delta_{g(t)}d_{g(t)}(y,\cdot)(x)) + \frac{\partial}{\partial t}d_{g(t)}(y,x) \right| \leq V(d_{g(t)}(x,y)). \quad (7)$$

**Lemma 6.** Let $(t_0, x_0) \in \text{Cut}_{g(t_0)}(o)$ and $\delta \in (0, \delta_1)$. Let $X$ be a $g(t)$-Brownian motion starting at $x_0$ at time $t_0$. Let $\tilde{T} := T \wedge (t_0 + \delta) \wedge \inf \{t \geq t_0 | d_{g(t)}(x_0, X_t) = \delta \}$. Then

$$E \left[ \rho(t \wedge \tilde{T}, X_{t \wedge \tilde{T}}) - \rho(t_0, x_0) - \int_{t_0}^{t \wedge \tilde{T}} V(\rho(s, X_s))ds \right] \leq 0.$$

**Proof.** We construct a point $\tilde{o} \in M$ as follows: we choose a minimizing unit-speed $g(t_0)$-geodesic $\gamma$ from $o$ to $x_0$ and define $\tilde{o} := \gamma(i_M/3)$. Then by construction $(t_0, x_0, \tilde{o}) \in A$. Moreover for all $t \in [t_0, \tilde{T}]$ we have $d((t_0, x_0, \tilde{o}), (t, X_t, \tilde{o})) < \delta_1$ and therefore $X_t \notin \text{Cut}_{g(t)}(\tilde{o})$. Let

$$\rho^+(t, x) := d_{g(t)}(o, \tilde{o}) + d_{g(t)}(\tilde{o}, x).$$

Since $\tilde{o}$ lies on a minimizing $g(t_0)$-geodesic from $o$ to $x_0$, we have $\rho^+(t_0, x_0) = \rho(t_0, x_0)$. Moreover, by the triangle inequality, $\rho^+(t, x) \geq \rho(t, x)$ for all $(t, x)$. On $[t_0, \tilde{T}]$,

$$d_{g(t)}(\tilde{o}, X_t) \geq d_{g(t)}(\tilde{o}, x_0) - d_{g(t)}(x_0, X_t) \geq \frac{i_M}{3} \delta \geq \frac{i_M}{3} \delta.$$

holds. By (7) and Lemma 4

$$\left( \frac{1}{2} \Delta_{g(t)} \rho^+ + \frac{\partial \rho^+}{\partial t} \right)(t, x) \leq V(\rho^+(t, x))$$

holds if $(t, x, \tilde{o}) \notin \text{Cut}_{ST}$. Note that $V(\rho^+(t, X_t)) = V(\rho(t, X_t))$ holds for all $t \in [t_0, \tilde{T}]$ since we can show $\rho(t, X_t) \geq i_M/3$ in a similar way as in (8). Therefore

$$\rho(t \wedge \tilde{T}, X_{t \wedge \tilde{T}}) - \rho(t_0, X_{t_0}) - \int_{t_0}^{t \wedge \tilde{T}} V(\rho(s, X_s))ds$$

$$= \rho(t \wedge \tilde{T}, X_{t \wedge \tilde{T}}) - \rho^+(t_0, X_{t_0}) - \int_{t_0}^{t \wedge \tilde{T}} V(\rho^+(s, X_s))ds$$

$$\leq \rho^+(t \wedge \tilde{T}, X_{t \wedge \tilde{T}}) - \rho^+(t_0, X_{t_0}) - \int_{t_0}^{t \wedge \tilde{T}} \left( \frac{1}{2} \Delta_{g(s)} \rho^+ + \frac{\partial \rho^+}{\partial s} \right)(s, X_s)ds.$$

Since $\rho^+$ is smooth at $(t, X_t)$ for $t \in [t_0, \tilde{T}]$, the last term is a martingale. Hence the claim follows. \square
For \( \delta \in (0, \delta_1) \), we define a sequence of stopping times \((S^\delta_n)_{n \in \mathbb{N}}\) and \((T^\delta_n)_{n \in \mathbb{N}_0}\) by

\[
T^\delta_0 := 0, \\
S^\delta_n := T \wedge \inf\{t \geq T^\delta_{n-1} \mid X_t \in \text{Cut}_{g(t)}(o)\}, \\
T^\delta_n := T \wedge (S^\delta_n + \delta) \wedge \inf\{t \geq S^\delta_n \mid d_{g(t)}(X_{S^\delta_n}, X_t) = \delta\}.
\]

Note that these are well-defined because \(\text{Cut}_{ST}\) and \(\{(t, x) \mid d_{g(t)}(y, x) = \delta\}\), where \(y \in M\), are closed.

**Proposition 1.** The process

\[
\rho(t, X_t) - \rho(0, X_0) - \int_0^t V(s, X_s)ds
\]

is a supermartingale.

**Corollary 1.** The process \(\rho(t, X_t)\) is a semimartingale.

**Proof of Proposition 1.** Thanks to the strong Markov property of Brownian motion it suffices to show that for all deterministic starting points \((t_0, x_0) \in [0, T] \times M\) and all \(t \in [t_0, T]\)

\[
E \left[ \rho(t, X_t) - \rho(t_0, X_{t_0}) - \int_{t_0}^t V(s, X_s)ds \right] \leq 0.
\]

To show this we first observe that thanks to Lemma 1 and Lemma 6 for all \(n \in \mathbb{N}\)

\[
E \left[ \rho(t \wedge S^\delta_n, X_{t \wedge S^\delta_n}) - \rho(t \wedge T^\delta_{n-1}, X_{t \wedge T^\delta_{n-1}}) - \int_{t \wedge T^\delta_{n-1}}^{t \wedge S^\delta_n} V(\rho(s, X_s))ds \mid \mathcal{F}_{T^\delta_{n-1}} \right] \leq 0
\]

and

\[
E \left[ \rho(t \wedge T^\delta_n, X_{t \wedge T^\delta_n}) - \rho(t \wedge S^\delta_n, X_{t \wedge S^\delta_n}) - \int_{t \wedge S^\delta_n}^{t \wedge T^\delta_n} V(\rho(s, X_s))ds \mid \mathcal{F}_{S^\delta_n} \right] \leq 0.
\]

It remains to show that \(T_n \to T\) as \(n \to \infty\). If \(\lim_{n \to \infty} T_n =: T_\infty < T\) occurs, then \(T^\delta_n - S^\delta_n\) converges to 0 as \(n \to \infty\). In addition, \(d_{g(t)}(X_{S^\delta_n}, X_{T^\delta_n}) = \delta\) must hold for infinitely many \(n \in \mathbb{N}\). Take \(N \in \mathbb{N}\) so large that \(C_1(T_\infty - T_n) < \delta/2\) for all \(n \geq N\). Then (6) yields \(d_{g(T_\infty)}(X_{S^\delta_n}, X_{T^\delta_n}) \geq \delta/2\) for infinitely many \(n \geq N\). But it contradicts with the fact that \(X_t\) is uniformly continuous on \([0, T]\). Hence \(T_n \to T\) as \(n \to \infty\). \(\Box\)

**Lemma 7.** \(\lim_{\delta \to 0} \sum_{n=1}^{\infty} |T^\delta_n - S^\delta_n| = 0\) almost surely.

**Proof.** For \(\delta > 0\), let us define a random subset \(E_\delta\) and \(E\) in \([0, T]\) by

\[
E_\delta := \{t \in [0, T] \mid \text{there exists } t' \in [0, T] \text{ satisfying } |t - t'| \leq \delta \text{ and } (t', X_{t'}, o) \in \text{Cut}_{ST}\}, \\
E := \{t \in [0, T] \mid (t, X_t, o) \in \text{Cut}_{ST}\}.
\]

Since the map \(t \mapsto (t, X_t, o)\) is continuous and \(\text{Cut}_{ST}\) is closed, \(E\) is closed and hence \(E = \cap_{\delta > 0} E_\delta\) holds. By the definition of \(S^\delta_n\) and \(T^\delta_n\), we have

\[
E \subset \bigcup_{n=1}^{\infty} [S^\delta_n, T^\delta_n] \subset E_\delta
\]

and hence the monotone convergence theorem implies

\[
\lim_{\delta \to 0} \sum_{n=1}^{\infty} |T^\delta_n - S^\delta_n| \leq \lim_{\delta \to 0} \int_0^T 1_{E_\delta}(t)dt = \int_0^T 1_E(t)dt = 0
\]

almost surely, where the last equality follows from Corollary 3. \(\Box\)
Lemma 8. The martingale part of $\rho(t,X_t)$ is
\[ \sum_{i=1}^{d} \int_{0}^{t} (U_s e_i) \rho(s,X_s) dW_s^i. \]

Proof. By the martingale representation theorem there exists an $\mathbb{R}^d$-valued process $\eta$ such that the martingale part of $\rho(t,X_t)$ equals $\int_{0}^{t} \eta_s dW_s$. Let
\[ N_t := \int_{0}^{t} \eta_s dW_s - \sum_{i=1}^{d} \int_{0}^{t} (U_s e_i) \rho(s,X_s) dW_s^i. \]
Using the stopping times $S_n^\delta$ and $T_n^\delta$, the quadratic variation $\langle N \rangle_T$ of $N$ is expressed as follows;
\[ \langle N \rangle_T = \sum_{i=1}^{d} \sum_{n=1}^{\infty} \left( \int_{S_{n-1}^\delta}^{S_n^\delta} |\eta^i_t - (U_t e_i) \rho(t,X_t)|^2 dt + \int_{T_{n-1}^\delta}^{T_n^\delta} |\eta^i_t - (U_t e_i) \rho(t,X_t)|^2 dt \right). \] (9)
Since $X_t \notin \text{Cut}_{g(t)}(o)$ if $t \in (T_{n-1}^\delta, S_n^\delta)$, Itô’s formula yields
\[ \int_{S_{n-1}^\delta}^{S_n^\delta} |\eta^i_t - (U_t e_i) \rho(t,X_t)|^2 dt = 0 \]
for $n \in \mathbb{N}$ and $i = 1, \ldots, d$. For the second term in the right-hand side of (9) we have
\[ \sum_{n=1}^{\infty} \int_{T_{n-1}^\delta}^{T_n^\delta} |\eta^i_t - (U_t e_i) \rho(t,X_t)|^2 dt \leq 2 \int_{\bigcup_{n=1}^{\infty} \{S_n^\delta \cap T_n^\delta\}} (|\eta^i|^2 + 1) dt. \]
Since $\eta^i$ is locally square-integrable on $[0,T]$ almost surely, Lemma 7 yields $\langle N \rangle_T = 0$ and the conclusion follows.

We can now conclude the proof of Theorem 2. Set $I^\delta := \bigcup_{n=1}^{\infty} \{S_n^\delta \cap T_n^\delta\}$. Set $L^\delta_t$ by
\[ L^\delta_t := -\rho(t,X_t) + \rho(0,X_0) + \sum_{i=1}^{d} \int_{0}^{t} (U_s e_i) \rho(s,X_s) dW_s^i \]
\[ + \int_{[0,t] \cap I^\delta} \left[ \frac{1}{2} \Delta g(t) \rho + \frac{\partial \rho}{\partial s} \right] (s,X_s) ds + \int_{[0,t] \cap I^\delta} V(\rho(s,X_s)) ds. \]
By Proposition 1, Lemma 8 and Itô’s formula on $[0,T] \setminus I^\delta$, $L^\delta_t$ is non-decreasing in $t$. In particular, $L^\delta_t$ can increase only when $t \in I^\delta$. Then we have
\[ \rho(t,X_t) - \rho(0,X_0) - \sum_{i=1}^{d} \int_{0}^{t} (U_s e_i) \rho(s,X_s) dW_s^i - \int_{0}^{t} \left[ \frac{1}{2} \Delta g(s) \rho + \frac{\partial \rho}{\partial s} \right] (s,X_s) ds + L^\delta_t \]
\[ = - \int_{[0,t] \cap I^\delta} \left[ \frac{1}{2} \Delta g(t) \rho + \frac{\partial \rho}{\partial s} \right] (s,X_s) ds - \int_{[0,t] \cap I^\delta} V(\rho(s,X_s)) ds. \] (10)
Since (7) yields
\[ \left| \int_{[0,t] \cap I^\delta} \left[ \frac{1}{2} \Delta g(t) \rho + \frac{\partial \rho}{\partial s} \right] (s,X_s) ds + \int_{[0,t] \cap I^\delta} V(\rho(s,X_s)) ds \right| \leq 2 \int_{I^\delta} V(\rho(s,X_s)) ds \]
and $V(\rho(s,X_s))$ is bounded on $I^\delta$, Lemma 7 yields that the right hand of (10) converges to 0 as $\delta \to 0$. Thus $L_t := \lim_{\delta \to 0} L^\delta_t$ exists for all $t \in [0,T]$ almost surely and hence (2) holds. We can easily deduce the fact that $L_t$ can increase only when $t \in \text{Cut}_{g(t)}(o)$ from the corresponding property for $L^\delta_t$. \qed
We define $k_1 \geq 1$ and $\bar{F} : [0, \infty) \to \mathbb{R}$ by
\[
k_1 := \inf \left\{ k \geq 1 \mid \text{Ric}_g(t)(x) \geq -(d-1)k^2 \text{ for } t \in [0, T] \text{ and } x \in M\right\},
\]
\[
\bar{F}(s) := k_1 \coth(k_1 \cdot s \wedge r_1) + k_1 \cdot s \wedge r_1,
\]
where $r_1$ is defined in (6).

Theorem 1 follows immediately from the following estimate of the drift part of (2):

**Proposition 2.** Suppose (11). Then, for all $(t, x) \in [0, T] \times M$ with $(t, x, o) \notin \text{Cut}_{ST}$,
\[
\Delta_{g(t)} \rho(t, x) + 2\frac{\partial \rho}{\partial t}(t, x) \leq \bar{F}(\rho(t, x)).
\]

To prove this proposition it suffices to show the following lemma:

**Lemma 9.** Suppose (11). Fix $t \in [0, T]$ and a minimizing unit-speed $g(t)$-geodesic $\gamma : [0, b] \to M$ with $\gamma(0) = 0$. Then there exists a non-increasing function $F : (0, b) \to \mathbb{R}$ satisfying $F(s) \leq \bar{F}(s)$ and
\[
\Delta_{g(t)} \rho(t, \gamma(s)) + 2\frac{\partial \rho}{\partial t}(t, \gamma(s)) \leq F(s)
\]
for all $s \in (0, b)$.

**Proof.** Let $(X_i)_{i=1}^d$ be orthonormal parallel fields along $\gamma$ with $X_1 = \dot{\gamma}$. Fix $r \in (0, b)$, and let $J_i$ be the Jacobi field along $\gamma|_{[0,r]}$ with $J_i(0) = 0$ and $J_i(r) = X_i(r)$. Then it is well known (see [4] for example) that
\[
(\Delta_{g(t)}d_{g(t)}(\gamma(0), \cdot))(\gamma(r)) = \sum_{i=2}^d I(J_i, J_i),
\]
where the index form $I$ for smooth vector fields $Y, Z$ along $\gamma|_{[0,r]}$ is defined by
\[
I(Y, Z) := \int_0^r \left(\langle \dot{Y}(s), \dot{Z}(s) \rangle_{g(t)} - \langle R_{g(t)}(Y(s), \dot{\gamma}(s))\dot{\gamma}(s), Z(s) \rangle_{g(t)}\right) ds.
\]

Let $G : [0, b] \to \mathbb{R}$ be the solution to the initial value problem
\[
\begin{cases}
G''(s) = -\frac{\text{Ric}_g(t)(\dot{\gamma}(s), \dot{\gamma}(s))}{d-1}G(s), \\
G(0) = 0, G'(0) = 1.
\end{cases}
\]

Then we have
\[
\sum_{i=2}^d I(GX_i, GX_i) = \sum_{i=2}^d \int_0^r \left[ |G'(s)X_i(s)|^2 - \langle R(G(s)X_i(s), \dot{\gamma}(s))\dot{\gamma}(s), G(s)X_i(s) \rangle \right] ds
\]
\[
= \int_0^r [(d-1)G'(s)^2 - G(s)^2 \text{Ric}(\dot{\gamma}(s), \dot{\gamma}(s))] ds
\]
\[
= (d-1) \int_0^r [G'(s)^2 + G(s)G''(s)] ds
\]
\[
= (d-1)G(r)G'(r).
\]
Since \( \gamma(0) \) has no conjugate point along \( \gamma \) on \([0, r]\), the left hand side of (1) must be strictly positive (see Theorem 2.10 in [1]). It follows that \( G(r) > 0 \) for all \( r \in (0, b) \). Now let \( Y_i(s) := \frac{G(s)}{G(r)} X_i(s) \). Note that \( Y_i \) has the same boundary values as \( J_i \). Therefore, by the index lemma,

\[
(\Delta_{g(t)} d_{g(t)}(\gamma(0), \cdot))(\gamma(r)) \leq \sum_{i=2}^{d} I(Y_i, Y_i) = \frac{(d-1)G'(r)}{G(r)}.
\]

Hence Lemma 4 and (1) yield

\[
(\Delta \rho + 2 \frac{\partial \rho}{\partial t})(t, \gamma(r)) \leq \frac{(d-1)G'(r)}{G(r)} + \int_{0}^{r} \text{Ric}(\dot{\gamma}(s), \dot{\gamma}(s))ds
= (d-1) \left[ \frac{G'(r)}{G(r)} - \int_{0}^{r} \frac{G''(s)}{G(r)}ds \right]
=: F(r).
\]

Since

\[
F'(r) = (d-1) \left[ \frac{G(r)G''(r) - G'(r)^2}{G(r)^2} - \frac{G''(r)}{G(r)} \right] = -\frac{(d-1)G'(r)^2}{G(r)^2} < 0,
\]

\( F \) is decreasing. In particular, we have \( F(r) \leq F(r \wedge r_1) \). A usual comparison argument implies \( G'(r \wedge r_1)/G(r \wedge r_1) \leq k_1 \coth(k_1 \cdot r \wedge r_1) \) and hence the conclusion follows. \( \Box \)

6 Generalization to non-symmetric diffusion

We generalise the previous results on more general setting including the case for non-symmetric diffusions. Let \( X_t \) be time-dependent diffusion whose generator is \( \Delta_{g(t)}/2 + Z(t) \), where \( Z(t) \) is a time-dependent vector field on \( M \) which is smooth on \([0, T] \times M \).

Even in this case, Theorem 2 still holds by replacing \( \Delta_{g(t)}/2 \) with \( \Delta_{g(t)}/2 + Z(t) \). In what follows, we briefly mention the proof. Except for Lemma 2 and Lemma 3, an extension of each assertion is straightforward. For Lemma 3, some difficulties come from the fact that the result corresponding to Lemma 2, especially the existence of a fundamental solution, is not yet known at this moment for non-symmetric diffusions. But, for our purpose, it suffices to show the following:

**Lemma 10.** Suppose that \( M \) is compact. Then \( P^x[X_t \in \text{Cut}_{g(t)}(o)] = 0. \)

**Proof.** Let \( \tilde{Z}(t) \) be a differential 1-form corresponding to \( Z(t) \) by duality with respect to \( g(t) \). Let \( M^Z_t \) be the martingale part of the stochastic line integral of \( \tilde{Z}(t) \) along \( X_t \). Note that there is a constant \( c > 0 \) such that \( \langle M^Z \rangle_t \leq ct \) holds since \( M \) is compact. Let us define a probability measure \( \tilde{P}^x \) on the same probability space as \( P^x \) by \( \tilde{P}^x[A] := E^x[\exp(-M^Z - \langle M^Z \rangle_t/2)1_A] \). By the Girsanov formula, the law of \( X_t \) under \( \tilde{P}^x \) coincides with that of \( g(t) \)-Brownian motion at time \( t \). The Schwarz inequality yields

\[
P^x[X_t \in \text{Cut}_{g(t)}(o)] \leq E^x \left[ e^{-\frac{\langle M^Z \rangle_t}{2}}1_{\{X_t \in \text{Cut}_{g(t)}(o)\}} \right]^{1/2} E^x \left[ e^{\frac{\langle M^Z \rangle_t}{2}} \right]^{1/2}
\leq \tilde{P}^x \left[ X_t \in \text{Cut}_{g(t)}(o) \right]^{1/2} e^{ct/2}.
\]

Hence the conclusion follows from Lemma 2. \( \Box \)

To state an extension of Theorem 11 define a tensor field \( (\nabla Z(t))^g \) by

\[
(\nabla Z(t))^g(X, Y) := \frac{1}{2} (\langle \nabla_X Z(t), Y \rangle_{g(t)} + \langle \nabla_Y Z(t), X \rangle_{g(t)}),
\]

where \( \nabla \) is the Levi-Civita connection with respect to \( g(t) \).
**Assumption 1.** There exists a locally bounded measurable function $b$ on $[0, \infty)$ so that

1. $(\nabla Z(t,x))^b + \partial_t g(t,x) \leq \text{Ric}_{g(t)}(x) + b(\rho(t, x))g(t, x)$ for all $t \in (0, T)$ and all $x \in M$.

2. The 1-dimensional diffusion process $y_t$ given by $dy_t = d\beta_t + (\bar{F}(y_t) + \int_0^y b(s)ds)dt$ does not explode. (This is the case if and only if $b(y) := \bar{F}(y) + \int_0^y b(s)ds$, see e.g. [8, Theorem 6.50] or [10, Theorem VI.3.2].)

Once we obtain the following, non-explosion of $X_t$ follows in the same way as above by the comparison argument.

**Lemma 11.** Suppose that Assumption 1 holds. Fix $t \in [0, T]$ and a minimizing unit-speed $g(t)$-geodesic $\gamma : [0, b] \to M$ with $\gamma(0) = 0$. Then there exists a constant $C_Z > 0$ depending only on $\{Z(t)\}_{t \in [0, T]}$ and $\gamma(0)$ such that

$$((\Delta_{g(t)} + Z(t))d_{g(t)}(\gamma(0), \cdot))(\gamma(s)) \leq C_Z + F(s) + \int_0^s b(d_{g(t)}(\gamma(0), \gamma(u)))du$$

for all $s \in (0, b)$, where $F$ is the same function as appeared in Lemma 4.

**Proof.** By a direct calculation, $(\nabla Z(t))^b(\dot{\gamma}(s), \gamma(s)) = \partial_u \langle Z(t), \dot{\gamma}(s) \rangle_{g(t)}(\gamma(s))$. Hence we obtain

$$(Z(t)d_{g(t)}(\gamma(0), \cdot))(\gamma(r)) = \langle Z(t), \dot{\gamma}(r) \rangle_{g(t)}(\gamma(r))$$

$$= \langle Z(t), \dot{\gamma}(0) \rangle_{g(t)}(\gamma(0)) + \int_0^t (\nabla Z(t))^b(\dot{\gamma}(s), \gamma(s))ds.$$  

Then, by setting $C_Z := \sup_{s \in [0, T]} \sup \{ \langle Z(s), X \rangle_{g(s)}(\gamma(0)) \mid X \in T_{\gamma(0)}M, \|X\|_{g(s)} = 1 \}$, the conclusion follows in a similar way as we did in the proof of Lemma 3. \hfill \Box
